Iron Compounds (*Chem.*) (1) FERROUS COMPOUNDS: In these iron is divalent. *Ferrous oxide*, FeO, is a black powder; takes fire in air; readily combines with carbon dioxide; it is prepared by reduction of ferric oxide in hydrogen at 300°, or by heating ferrous oxalate out of contact with air. *Ferrous hydroxide*, $Fe(OH)_2$: A white solid; rapidly oxidises in air, turning first a dirty green colour, then reddish brown, owing to formation of hydrated ferric oxide; it is prepared by mixing air free solutions of caustic soda and ferrous sulphate out of air. *Ferrous chloride*, $FeCl_2$: Forms white crystalline scales when anhydrous, green crystals containing $6H_2O$ when obtained by evaporation of its aqueous solution. Vapour density at low temperature corresponds to formula Fe_2Cl_4, at high temperature to $FeCl_2$. Heated in air it gives Fe_2O_3. Forms double salts with alkali chlorides, *e.g.* $FeCl_2 2NH_4Cl$. Dissolves nitric oxide, forming a dark brown solution. Anhydrous salt, obtained by passing dry hydrogen chloride over heated iron; crystallised salt, obtained by dissolving iron or ferrous sulphide in hydrochloric acid, and crystallising the solution. *Ferrous sulphate*, $FeSO_4$: A white solid obtained by heating the crystallised salt carefully till all water of crystallisation is expelled. Ordinarily met with as green crystals, $FeSO_4 7H_2O$, which are called *green vitriol* or *copperas*; in this form it is isodimorphous with magnesium sulphate. Its solution oxidises on exposure to air, forming hydrated ferric oxide and ferric sulphate; it dissolves nitric oxide, forming a dark brown solution, a property made use of in testing for nitrates. It forms double salts with alkaline sulphates, *e.g.* ferrous ammonium sulphate, $FeSO_4(NH_4)_2SO_4 6H_2O$, which is more stable in air than ferrous sulphate, and is therefore used in standardising solutions of potassium permanganate and dichromate for use in volumetric analysis. Ferrous sulphate is used as a reducing agent, *e.g.* it reduces gold from a solution of gold chloride. It was formerly used in making Nordhausen sulphuric acid by partial roasting and subsequent distillation. It may be obtained by dissolving iron or ferrous sulphide in dilute sulphuric acid, and crystallising the solution. On the large scale iron pyrites, FeS_2, are exposed to air, and moistened with water; rapid oxidation occurs, and from the mass ferrous sulphate can be obtained by extraction with water and crystallising the solution. Ferrous sulphate is largely used in making ink. *Ferrous iodide*, FeI_2: Obtained by heating finely divided iron in iodine vapour out of air; is remarkable as being a dark red brown crystalline solid, other ferrous salts being white. (2) FERRIC COMPOUNDS: In these iron is trivalent. *Ferric oxide*, Fe_2O_3: A reddish brown powder; only soluble in acids with difficulty, after it has been strongly heated; insoluble in water; easily reduced to the metal by heating in hydrogen or carbon monoxide; less easily by heating with carbon. It is obtained by heating the hydroxide and many salts of iron in air. When obtained by heating ferrous sulphate it is used for polishing purposes under the name of jewellers' rouge. It is a common ore of iron (*q.v.*) *Ferric hydroxide*, $Fe(OH)_3$: Obtained as a slimy dark brown precipitate when ammonia is added to a solution of ferric chloride in the cold; on warming, the precipitate becomes granular. When heated it forms ferric oxide. It dissolves in ferric chloride solution, and on submitting this product to dialysis (*q.v.*), it is obtained in a soluble colloidal form. This solution is used in medicine under the name of *dialysed iron*; it does not show the ordinary reactions of iron, and it is precipitated by addition of solutions of salts. Hydrated ferric oxides, containing less water than ferric hydroxide, are formed when iron rusts in moist air. It has the property of fixing colouring matters on fabrics (cotton, linen, etc.), and on this account many ferric salts which are hydrolysed by water, such as the nitrate, acetate, and sulphate, are used as mordants; *e.g.* $Fe(NO_3)_3 + 3H_2O = Fe(OH)_3 + 3HNO_3$. Hydrated oxides of iron are important ores of iron (*q.v.*) *Ferric chloride*, $FeCl_3$: Is a red brown solid with a green lustre when anhydrous; this form is obtained by heating iron in a rapid stream of chlorine. When obtained by evaporating its aqueous solution to the solidifying point, it forms brownish yellow crystals of the composition $FeCl_3 6H_2O$. A solution of ferric chloride can be prepared by dissolving iron in hydrochloric acid, and passing chlorine into the solution, or oxidising the solution with nitric acid, $6FeCl_2 + 6HCl + 2HNO_3 = 6FeCl_3 + 2NO + 4H_2O$; also by dissolving ferric hydroxide in hydrochloric acid. Anhydrous ferric chloride boils at about 280°, and its vapour density corresponds to the formula Fe_2Cl_6 just above its boiling point; at higher temperatures to $FeCl_3$. It is soluble in alcohol; it is used in organic chemistry as a "halogen carrier," *e.g.* nitrobenzene is converted by chlorine in presence of $FeCl_3$ into metachlornitrobenzene. The solution of ferric chloride is partly hydrolysed by water, completely at great dilutions, $FeCl_3 + 3H_2O = Fe(OH)_3 + 3HCl$; so that it always reacts acid to litmus. It is an oxidising agent, *e.g.* $2FeCl_3 + H_2O + H_2SO_3 = H_2SO_4 + 2HCl + 2FeCl_2$. It coagulates albumin. Solutions of ferric chloride in water and in alcohol are used in medicine. *Ferric sulphate*, $Fe_2(SO_4)_3$: A pale yellowish white

solid which dissolves in water plentifully, but slowly. It may be prepared by adding sulphuric acid to ferrous sulphate, and oxidising with nitric acid, $6FeSO_4 + 3H_2SO_4 + 2HNO_3 = 3Fe_2(SO_4)_3 + 2NO + 4H_2O$. It forms alums with the alkali sulphates, *e.g.* $K_2SO_4Fe_2(SO_4)_3 24H_2O$. *Ferric acetate*, $Fe(C_2H_3O_2)_3$: Forms a deep red uncrystallisable solution, which forms an insoluble basic acetate, $Fe(OH)_2(C_2H_3O_2)$, on heating. Use is made of this property in analysis to separate iron from other metals. (3) OTHER COMPOUNDS OF IRON: *Ferrosoferric oxide*, Fe_3O_4: Also called magnetic oxide of iron. Occurs naturally, and is an important ore of iron (*q.v.*) Obtained as a dark brown solid by passing steam over heated iron. As its name implies, it is magnetic. It is formed as a thin layer on iron in Barff's process (*q.v.*) Chemically it behaves as if it were a compound of ferrous and ferric oxides, $Fe_3O_4 = FeO_6Fe_2O_3$. *Sulphides of iron;* Ferrous sulphide, FeS, is obtained as a dark grey solid on heating iron and sulphur together; also as a black precipitate when ammonium sulphide is added to a soluble iron salt. It is this compound which causes the blackening of the teeth and faeces after taking iron. It readily dissolves in acids, forming a ferrous salt, and evolving sulphuretted hydrogen. *Iron disulphide*, FeS_2: Also called Iron Pyrites, or Mundic, when it occurs crystallised in the regular system: Marcasite when it occurs crystallised in the triclinic system. Heated out of air it loses a part of its sulphur; heated in a current of air it forms sulphur dioxide and ferric oxide, and on this account is used in enormous quantities for the manufacture of sulphuric acid. *See also* FERROUS SULPHATE. *Ferrates:* When a mixture of finely divided iron and potassium nitrate is heated, it takes fire, and from the product when cold a solution of potassium ferrate is obtained on adding water. The formula of the salt is K_2FeO_4. Caustic potash precipitates it from the concentrated solution. It is black, and forms red solutions; only stable when very concentrated. *Iron carbonyl:* A brownish liquid of the probable formula $Fe(CO)_5$; very volatile; slowly formed when carbon monoxide is passed over gently heated, finely divided iron. *See also* POTASSIUM FERROCYANIDE *and* FERRICYANIDE, *and* PRUSSIAN BLUE. W. H. H.

Iron, Cutting. The word "iron" is applied to the cutting part of tools that have steel cutters, such as planes.

Irone (*Chem.*) *See* TERPENES.

Iron Founding. The process of making iron castings. It consists essentially of the processes of (1) MOULDING (*q.v.*); (2) Pouring in the molten iron which has usually been melted in a CUPOLA FURNACE (*see* FURNACES); (3) Breaking up the mould when the casting has cooled sufficiently; and (4) TRIMMING or FETTLING (*q.v.*) the casting, which is then ready to leave the foundry.

Iron Losses (*Elect. Eng.*) That part of the energy which is lost in a transformer (*q.v.*) or similar electromagnetic apparatus, through the Foucault or eddy currents (*q.v.*) and the HYSTERESIS (*q.v.*) The amount of the former loss is uncertain, but it may be reduced to a very small amount by laminating the core. *See* LAMINATION. The amount of energy lost by hysteresis depends upon the quality of the iron and the value of the magnetic induction in the iron. According to the well known formula of Steinmetz, if B be the induction, *h* a coefficient depending on the nature of the iron and the unit of mass chosen, then W, the work lost during each complete magnetic cycle, is given by the equation:

$$W = hB^{1.6}$$

Iron Ores (*Min.*) The principal ores of iron are the oxides HÆMATITE and MAGNETITE, the hydrates LIMONITE, TURGITE, GÖTHITE, and the carbonates CHALYBITE (or SIDERITE), and CLAY IRONSTONE (*q.v.*) *See also* IRON *and* IRON COMPOUNDS. There are many minerals besides (*e.g.* Iron Pyrites) which contain a large amount of iron, but owing to the presence of other elements (such as sulphur and phosphorus), which cannot be easily separated from the metal, they are not classed commercially as iron ores.

Iron Painting (*Dec.*) This work differs from ordinary house painting, because the surface is almost non-absorbent, while the principal object of the paint is to prevent rusting. The best paint for iron has long been the subject of discussion among engineers and painters. Red lead is generally favoured, but oxide of iron has also many adherents. Probably better than either are the several special iron paints manufactured for the purpose. When red lead is used it is mixed with boiled oil, and quickly dries very hard. The London County Council usually specifies white lead for repainting iron, but this is contrary to the opinion of those who have closely studied the subject. In repainting iron it is quite essential that all traces of grease, dirt, and rust be removed before the new paint is applied. A blow lamp or solvents are usually employed to remove the grease, while the rust is got rid of by thorough scraping and the use of wire brushes.

Iron Pattern (*Foundry*). A pattern (*q.v.*) is often made of iron in cases where a large number of castings have to be made from it. The iron pattern is itself a casting, and is made from an original wooden pattern, in which double contraction (*q.v.*) has to be allowed for.

Iron Pyrites (*Min.*) Sulphide of iron, FeS_2. Iron = 47, sulphur = 53 per cent. Cubic, in brassy yellow crystals or massive in radiating forms. It is hard and brittle. It was formerly used as a substitute for flint in firearms; now chiefly used in the manufacture of sulphuric acid, sulphate of iron, and alum. It nearly always contains a trace of gold, for which metal it is often mistaken, but from which it is at once distinguished by its hardness and brittleness. In some cases enough gold is present to pay as an ore of gold. Pyrites is of world wide distribution. Many dark clays and other coloured rocks owe their colour to finely disseminated Pyrites.

Iron Rope. Usually termed WIRE ROPE (*q.v.*)

Iron Stain on Linen. *See* CELLULOSE.

Ironstone. A general term for IRON ORE (*q.v.*)

Iron Tubing (*Eng., etc.*) *See* TUBING.

Ironwood. *See* WOODS.

Irradiation (*Phys.*) The name given to a peculiar optical effect in consequence of which very luminous bodies—for instance, an incandescent lamp filament—appear larger than the actual size. It is supposed to indicate that when a part of the retina is very strongly stimulated, the adjacent portions are also slightly affected, giving the sensation of light.

Irrationality of Dispersion (*Light*). Prisms of different materials under exactly similar conditions produce spectra of different lengths. If, however,

the spectra be made of equal lengths, and be made to correspond in one part, it will be found that they do not correspond in other parts, the separation of two given spectral lines depending upon the substance of the prism.

Irregular Pass (*Textiles*). *See* ENTERING.

Irregular Reflection (*Light*). Reflection which occurs at other than polished surfaces. Such surfaces are equivalent to myriads of small mirrors set at all angles, and their effect is to scatter the light in all directions. A typical instance is white unglazed paper. Even the smoothest surface is to some extent rough, and in consequence diffuses some light.

Irreversible Cycles (*Phys.*) When the pressure, volume, and temperature of a substance are altered in such a way that after a series of changes the substance returns to its original state, it is said to pass through a "cycle" of operations, and when the series of changes can only take place in one way the cycle is said to be "irreversible." For instance, if the substance during the cycle comes into contact with another body at a higher temperature than its own, then the operation is irreversible, for if it be attempted to perform the cycle the reverse way, at this particular point it is necessary that heat should pass from the cold substance to the hot body, which will not happen. Practical changes are almost inevitably irreversible. *Cf.* REVERSIBLE CYCLES.

Irrigation (*Civil Eng.*) The artificial supply of water for agricultural purposes. Usually effected by open channels on the surface of the land, and not by pipes or conduits.

—— (*Sewage*). The distribution of sewage over a large surface of ordinary agricultural ground, having in view a maximum growth of vegetation (consistent with due purification) for the amount of sewage supplied. The soil should be porous, as it is essential that the sewage should not only run over but through the soil before passing out as an effluent. On an average one acre of land is required for every hundred persons.

Isatin (*Chem.*), $C_6H_4<^{CO}_{NH}>CO$. Yellowish red prisms; melts at 201°; soluble in water and in alcohol. It dissolves in caustic soda solution with a violet colour; but on standing, the solution turns yellow, owing to the formation of the sodium salt of isatinic acid, $C_6H_4<^{CO.COONa}_{NH_2}$. Its chemical behaviour is that of a ketone (*q.v.*); but with phosphorus pentachloride it gives isatin chloride, $C_6H_4<^{CO}_{N}\geqslant C.Cl$. The latter compound is reduced to indigo by zinc dust. It was first obtained by oxidation of indigo with nitric acid. In some of its reactions (*e.g.* formation of salts with alkalis) isatin behaves according to the tautomeric form $C_6H_4<^{CO}_{N}\geqslant C.OH$, which is called PSEUDOISATIN.

Isatis Tinctoria (*Botany*). The WOAD PLANT belongs to the order *Cruciferae*, and yields a dye by fermentation of the leaves. The dye is now superseded by indigo.

Ischium (*Zoology*). The posterior bone of the hip girdle.

Isentropic Lines (*Heat*). Lines or curves of constant entropy. Frequently used as another name for ADIABATIC LINES, but the two are only synonymous in the case of reversible changes.

Isinglass. A refined form of gelatine obtained from fish membranes, especially the sturgeon. *See* ACCIPENSER *and* GELATINE.

Isinglass Gold Size (*Dec.*) Made from Russian isinglass. It is dissolved in water by means of heat, and afterwards added to spirits of wine, and then strained or filtered. It is used for gilding on glass.

Isis Headed Capital (*Architect.*) *See* HATHOR HEADED CAPITAL.

Iso- (*Chem.*) A prefix used in chemical nomenclature to indicate that the compound or group of compounds whose name or names begin with the prefix are isomeric (*see* ISOMERISM) with the compound or group of compounds having the same name, minus the prefix "iso." Examples:

$$\begin{array}{c} CH_3 \\ | \\ CH_2 \\ | \\ CH_2OH \end{array} \qquad\qquad \begin{array}{c} CH_3 \\ | \\ CHOH \\ | \\ CH_3 \end{array}$$

Propyl Alcohol. Isopropyl Alcohol.

Another example is afforded by methyl cyanide, CH_3CN, and methyl isocyanide, CH_3NC.

Isobar *or* **Isobaric Line** (*Meteorol.*) A line (or surface) in the air, at all points of which the barometric pressure has the same value.

Isobarometric Charts (*Meteorol.*) Charts on which lines are drawn through regions having simultaneously the same readings of the barometer.

Isobars (*Phys.*) Lines or curves showing the relation between the volume and temperature of a body when its pressure is constant. Also known as ISOPIESTIC LINES.

Isobilateral Leaf (*Botany*). The term applied to a type of leaf where the blade is vertical, *e.g.* IRIS.

Isocheimals (*Meteorol.*) Lines drawn on a map through regions which have equal winter temperatures.

Isochromatic Curve (*Phys.*) A term used to denote a line along which the colour is uniform in the case of the colour phenomena displayed by crystals in convergent polarised light.

Isochromatic Photography. Another name for ORTHOCHROMATIC PHOTOGRAPHY (*q.v.*) *See also* PHOTOGRAPHY.

Isochronism (*Watches and Clocks*). The performance of *unequal* arcs of vibration in *equal* intervals of time.

Isochronous (*Phys.*) Having equal times. Applied to uniform motion, or more correctly to two or more different motions which occur in the same time, *e.g.* two pendulums which swing exactly in time with each other.

Isoclinic Lines (*Phys.*, *Meteorol.*) Lines connecting those parts of the Earth's surface at which the magnetic inclination or dip is the same.

Isocyanides (*Chem.*) *Also called* CARBYLAMINES, CARBAMINES, *or* ISONITRILES. Compounds of the formula $R-NC$, where R stands for an alcohol radical. They are isomeric with the organic cyanides or nitriles which have the formula $R-CN$. They are distinguished from the latter by having a disagreeable smell, lower boiling points, and by their reactions. They are obtained by heating an alkyl

iodide with silver cyanide; also by heating a primary amine with chloroform and alcoholic potash:

$$C_2H_5I + AgCN = C_2H_5NC + AgI.$$
$$C_6H_5NH_2 + CHCl_3 + 3KOH = \underset{\text{Phenyl Isocyanide.}}{C_6H_5NC} + 3KCl + 3H_2O.$$

The isocyanides are liquids, sparingly soluble in water, readily soluble in alcohol and ether; they all have the same disagreeable smell, which produces nausea and headache. When heated they undergo rearrangement into cyanides; with acids they undergo hydrolysis to amines and formic acid:

$$C_2H_5NC + 2H_2O = C_2H_5NH_2 + HCOOH.$$

Their formation from and decomposition into primary amines proves that the nitrogen is attached to carbon. Methyl isocyanide boils at 59°, ethyl isocyanide at 79°, and phenyl isocyanide at 166°, at the same time polymerising. Their formation is used as a test for primary amines and chloroform.

Isocyclic Ring (*Chem.*) *See* CLOSED CHAIN COMPOUNDS.

Isodynamic Lines (*Phys.*, *Meteorol.*) Lines connecting those parts of the Earth's surface at which the total magnetic intensity (in the line of dip) is the same.

Isogeothermic Lines (*Phys.*, *Meteorol.*) Lines connecting those places on the Earth's surface at which the mean temperature of the soil is the same.

Isogonic Lines (*Phys.*, *Meteorol.*) Lines connecting those parts of the Earth's surface at which the magnetic declination is the same.

Isohels (*Meteorol.*) Lines connecting places having the same amount of sunshine.

Isohydric Solutions (*Chem.*) Solutions of substances (salts, acids, bases) having a common ion, of such strength that the concentration (gram molecules per litre) of the ion in each solution is the same. Such solutions undergo no change when they are mixed.

Isohyets (*Meteorol.*) Lines connecting places having the same amount of rainfall.

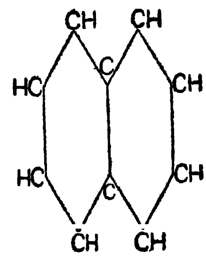
Isomerism. Compounds composed of the same elements and having the same molecular weight are said to be isomeric. There are various kinds of isomerism. When the same atom or group of atoms is substituted at different places in the molecule of a parent compound, we have POSITION ISOMERISM; *e.g.* propane yields normal and isopropyl alcohols and iodides:

CH_3	CH_3	CH_3	CH_3	CH_3
$\vert$	$\vert$	$\vert$	$\vert$	$\vert$
CH_2	CH_2	$CHOH$	CH_2	CHI
$\vert$	$\vert$	$\vert$	$\vert$	$\vert$
CH_3	CH_2OH	CH_3	CH_2I	CH_3
	Normal Propyl Alcohol.	Isopropyl Alcohol.	Normal Propyl Iodide.	Isopropyl Iodide.
	Isomeric.		Isomeric.	

When different radicals are united together by means of a di- or polyvalent element to form compounds which fulfil the requirements of the above definition of isomeric compounds, we have what is called METAMERISM; *e.g.* the following ethers are metameric, also the amines:

$$\underset{\text{Methylpropyl Ether.}}{\begin{matrix}CH_3\\C_3H_7\end{matrix}\!\!>O} \quad \underset{\text{Diethyl Ether.}}{\begin{matrix}C_2H_5\\C_2H_5\end{matrix}\!\!>O} \quad \underset{\text{Trimethylamine.}}{\begin{matrix}CH_3\\CH_3\\CH_3\end{matrix}\!\!>N} \quad \underset{\text{Methylethylamine.}}{\begin{matrix}C_2H_5\\CH_3\\H\end{matrix}\!\!>N} \quad \underset{\text{Normal and Isopropylamines.}}{\begin{matrix}C_3H_7\\H\\H\end{matrix}\!\!>N}$$

When the same atoms or groups of atoms are similarly united chemically, but have a different spacial arrangement, we have what is called Stereoisomerism or Geometrical Isomerism. This form of isomerism is dealt with separately. *See* STEREOISOMERISM. The number of isomerides derivable from one parent compound increases very rapidly with the increase of complexity of the compound. While butane has only two isomeric forms, $CH_3CH_2CH_2CH_3$ and $(CH_3)_2.CH.CH_3$, tridecane, $C_{13}H_{28}$, has 802 isomerides. Naphthalene—



has ten isomerides when two hydrogen atoms are replaced by two different atoms or groups, but over 10,000,000 isomerides when eight hydrogens are replaced by eight different groups. It must not be inferred that if two compounds are isomeric they are easily converted into each other, or are even nearly related. This may be so or not. Hydrazobenzene is easily converted into benzidine, $C_6H_5NH.NH.C_6H_5 \rightarrow H_2N.C_6H_4.C_6H_4NH_2$; but these isomerides are widely different chemically. Propyl alcohol is not readily changed to isopropyl alcohol, but both these substances have certain properties in common. The most numerous examples of isomerism are to be found in organic chemistry; but in recent years numerous examples have been discovered in inorganic chemistry. Examples are: the sodium potassium sulphites, $SO_2\!<\!\begin{matrix}OK\\Na\end{matrix}$ and $SO_2\!<\!\begin{matrix}ONa\\K\end{matrix}$; the sodium potassium thiosulphates, $SO_2\!<\!\begin{matrix}OK\\SNa\end{matrix}$ and $SO_2\!<\!\begin{matrix}ONa\\SK\end{matrix}$; the chromium bromides,

$$\underset{\substack{\text{Blue.}\\\text{All Br precipitated}\\\text{by }AgNO_3.}}{[Cr(H_2O)_6]Br_3} \text{ and } \underset{\substack{\text{Green.}\\\frac{1}{3}\text{ Br precipitated}\\\text{by }AgNO_3.}}{\left[Cr\begin{matrix}Br_2\\(H_2O)_4\end{matrix}\right]Br2H_2O.}$$

See also, in connection with this subject, TAUTOMERISM *and* WERNER'S THEORY.

Isometric Lines (*Phys.*) Lines or curves showing the relation between the pressure and temperature of a body when its volume is constant. Also known as ISOPLERES.

Isomorphism (*Chem.*) Literally means having the same form. In chemistry it is used to indicate the identity of crystalline form shown by compounds containing similar elements similarly combined together. The following are examples of isomorphous compounds:—The alums: they have the general formula $R_2SO_4M_2(SO_4)_3 24H_2O$; the double sulphates of the general formula $R_2SO_4MSO_4 6H_2O$, when R = K, NH_4, or Na, and M = Mg, Mn, Fe, Co, or Ni; the arseniates and phosphates, as sodium arseniate, $Na_2HAsO_4 12H_2O$, and sodium phosphate, $Na_2HPO_4 12H_2O$; the sulphates and chromates, as K_2SO_4 and K_2CrO_4. The term is also applied to the elements occurring in isomorphous groups; for

instance, aluminium, chromium, iron, and manganese are sometimes called isomorphous elements because the alums form an isomorphous group. Identity of crystalline form is not by itself a proof of isomorphism: thus potassium nitrate crystallises in the same form as arragonite—a form of calcium carbonate; but these substances are not isomorphous, for calcium and carbon are not similar elements to potassium and nitrogen. A good test of isomorphism besides similarity of form is the formation of mixed crystals. Thus a crystal of common alum will grow in a solution of chrome alum by having the latter deposited on it in such a way that the shape of the crystal does not alter; or a mixed solution of these two alums will deposit crystals containing both alums, while their shape is that of alum or chrome alum. The identity of crystalline form in isomorphous substances is not perfect, the angles between corresponding faces in two isomorphous substances being usually slightly different. The principle of isomorphism has occasionally been of use in atomic weight determinations. Thus aluminium is isomorphous with iron in a number of compounds, so that if ferric oxide has the formula Fe_2O_3, the isomorphous aluminium oxide will most probably have the formula Al_2O_3; so that if the percentage composition of this oxide is known, the atomic weight of aluminium is known. One element may belong to more than one isomorphous group. Manganese is isomorphous with iron in its sulphate and in its alums; it is isomorphous with sulphur in the manganates and sulphates, *e.g.* K_2MnO_4 and K_2SO_4; it is isomorphous with chlorine in the permanganates and perchlorates, *e.g.* $KMnO_4$ and $KClO_4$.—W. H. H.

Isomorphism (*Min.*) The identity in form of some minerals of the same groups. Isomorphous minerals can and do replace one another to a considerable extent; *e.g.* the sulphide of lead, GALENA, is often partially replaced by the isomorphous sulphide of silver, ARGENTITE, without any apparent alteration in the crystal of Galena.

Isonephs (*Meteorol.*) Lines connecting places having the same amount of cloudiness.

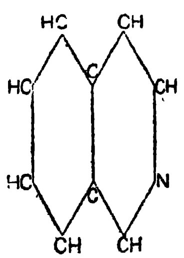
Isonitriles (*Chem.*) *See* ISOCYANIDES.

Isonitroso Compounds (*Chem.*) *See* NITROSO COMPOUNDS.

Isopiestic Lines (*Phys., Meteorol.*) *See* ISOBARS.

Isopleres (*Phys.*) *See* ISOMETRIC LINES.

Isoquinoline (*Chem.*)



A colourless crystalline solid; melts at 23°; boils at 240°. Its properties and behaviour are similar to those of quinoline (*q.v.*) It occurs in coal tar, and is obtained from this source. On oxidation it yields phthalic acid and cinchomeronic acid. It is used in the preparation of the dye quinoline red, and is of importance as being the parent substance of a number of alkaloids, *e.g.* Papaverine and Narcotine.

Isotherals (*Meteorol.*) Lines drawn on a map through regions which have equal summer temperature.

Isothermal Change (*Phys.*) A change in the pressure and volume of a substance, especially of a gas, which occurs without change of temperature.

Isothermal Charts (*Meteorol.*) Charts on which lines are drawn through regions having simultaneously the same readings of the thermometer.

Isothermal Line *or* **Curve** (*Phys.*) A curve showing the relation between the changes of pressure and volume of a substance which is kept at constant temperature. For a perfect gas the curve is a hyperbola, and is represented by the equation PV = a constant.

Isotherms (*Meteorol.*) Lines connecting places having an equal temperature.

Isothiocyanates (*Chem.*) *See* MUSTARD OILS.

Isotonic Solutions (*Chem.*) Solutions having the same osmotic pressure (*q.v.*)

Isotropic Body (*Phys.*) A body homogeneous in all directions as regards its physical properties.

Istesso tempo, l' (*Music*). The same time; put after an alteration of time to show that the former tempo is to be resumed, or as warning that there is to be no change in the time.

Italian (*Textile Manufac.*) A lining fabric, usually with a five end weft sateen weave. Highly polished in the finishing and pressing.

Italian Pink (*Dec.*) A pigment similar to Dutch pink (*q.v.*)

Italian Schools of Painting. *See* PAINTING, SCHOOLS OF

Italic, Italics (*Typog.*) The name applied to a printing type invented about 1500 by Aldus Manutius, a Venetian printer. Italic type or italics are employed in modern books, etc., to attract the attention of the reader, for emphasis, or to distinguish a word or phrase from others in the same context. The words in parentheses which follow the terms in this work are set in italics.

Ivory (*Zool.*) The toothlike substance of the tusks of elephants and also of the teeth and tusks of the narwhal, boar, and hippopotamus.

——, Artificial. A form of CELLULOID (*q.v.*) often used as an imitation of and substitute for ivory.

Ivory Black (*Dec.*) This is made by calcining waste cuttings of ivory. It is of an intense black colour, tending toward a bluish hue; is not a good drier, but makes a good glaze. *See* GLAZING. Much so-called ivory is real boneblack

Ivory, Vegetable (*Botany*). The ripe seeds of the ivory nut palm or Corozo nut, ***Phytelephas macrocarpa*** (order, *Palmæ*), a native of Central America. The hard albumen is much used for making small articles, which are turned in the lathe.

J (*Phys.*) The symbol for JOULE'S EQUIVALENT (*q.v.*)

Jaborandi. A powerful sudorific drug derived from the dried leaflets of a Brazilian shrub, ***Pilocarpus pennatifolius*** (order, ***Rutaceæ***). The alkaloid Pilocarpine and its salts are used in ophthalmic practice.

Jack. A term applied to a great variety of mechanical contrivances, often to machines which have taken the place of human labour, *e.g.* the automatic machine for turning a spit in roasting meat. Applied to a form of roller, winch, a wedge used in mining, an oscillating lever, to a spring clip forming the terminal in a telegraph or telephone wire by means of which instruments can be rapidly brought into circuit, etc., etc.

—— (*Archæol.*) A vessel made of waxed leather, used either for holding liquor (*see* BLACK JACK) or for drinking from, *e.g.* a mug or tankard.

—— (*Arm.*) A sleeveless tunic or coat of fence, usually made of leather, worn by footmen and archers from the fourteenth to the sixteenth century. Later forms of the Jack were plated with iron. The Jack was succeeded by the BUFF COAT (*q.v.*)

—— (*Eng.*) A piece of mechanism, usually portable, used for lifting heavy weights through a short distance; *e.g.* lifting a heavy vehicle so that its wheels are off the ground. It is usually worked by hand, the force being applied by levers, or by a screw in a SCREW JACK or BOTTLE JACK, or by a small hydraulic press in the case of a HYDRAULIC JACK.

—— (*Lace Manufac.*) A term used in the lace trade. It has various meanings; *e.g.* a frame of wood or iron with projecting wires to hold bobbins filled with material. This description applies to the jack used by the warper, and is analogous to the term "creel" used in the weaving trade. *See also* JACKS.

Jacket (*Eng., etc.*) A general term for a casing used to keep some object at a constant temperature; *e.g.* a STEAM JACKET (*q.v.*) or a WATER JACKET (*q.v.*)

—— (*Paper Manufac.*) A special felt cover for the couch roll, which serves to remove excess water from wet paper during manufacture.

Jack Frame (*Cotton Spinning*). A fine gauge on the roving frame with one row of flyer spindles only. Used for producing fine rovings for very fine spun yarns.

Jacking Delivery Motion (*Cotton Spinning*). Used on fine spinning mules for delivering a short length of roving through draw rollers after "jacking" has taken place, to compensate for the contraction during twisting.

Jacking Motion (*Cotton Spinning*). Used on fine spinning mules for stopping delivery of roving through rollers, just before the carriage reaches the end of its traverse outwards. By this means an extra draft is given to the spun thread.

Jacking Off (*Spinning*). The motion in mule spinning for reversing the twist or taking out the excessive twine in the yarn, near the top of the spindle, before winding on to the latter.

Jacking Up (*Eng.*) Lifting a heavy object by means of a JACK (*q.v.*)

Jack in the Box (*Cotton Spinning*). *See* DIFFERENTIAL MOTION.

Jack Off (*Lace Manufac.*) To wind short lengths of thread off a number of bobbins, and make them into one continuous length.

Jack Plane (*Carp.*) The plane used for roughing out wood and producing an approximately true surface. Its length is usually from 15 to 18 in., and the width of the cutting iron 2 to $2\frac{1}{2}$ in. English jack planes are usually made of beech. Iron planes are much used in America, and are being gradually introduced in England.

Jack Rafters (*Carp.*) The short rafters fixed to the hip rafters. *See* ROOFS.

Jacks (*Lace Manufac.*) The SELECTORS or INTERCEPTORS used in the lace curtain machine.

—— (*Textile Manufac.*) A type of lever in dobby looms in connection with the lowering and lifting of the heald shafts.

Jacobean Architecture. *See* RENAISSANCE ARCHITECTURE.

Jacquard (*Cotton Weaving*). A pattern machine used for the production of floral and other ornamental designs in cloth weaving where the adoption of tappet or dobby would be useless. These machines are specially constructed for different kinds of work, the chief makes being SINGLE CYLINDER, TWO CYLINDER, CROSS BORDER, and TWILLING JACQUARD.

—— (*Lace Manufac.*) Mechanism connected to the lace machine for the purpose of producing the fabric. (Jacquards vary considerably in their application to the various machines used in the textile trades.) The form best adapted for lace curtain machines is a special form of MANCHESTER TOP, and for the "Levers" machine a modification known as the "SPRING DROPPER" JACQUARD, wherein the various movements of the guide bars are accomplished by the aid of droppers (*q.v.*) or wedges. Great accuracy of movement is attained by the latter method. *See also* SILK WEAVING.

Jade (*Min.*) A compact tough silicate of magnesium and calcium of variable composition. It is much used by the Maoris for weapons and by the Chinese in the manufacture of cups, images, rings, etc. Also called Nephrite and Axe Stone. Distinguished from Jadeite, which is a sodium aluminium silicate. Jade comes chiefly from China, New Zealand, Corsica, and North America.

Jag Bolt (*Eng.*) A bolt roughened on the part of its axis or shaft above the screw, in order that it may be held fast by the material (wood, lead, etc.) in which it is embedded.

Jalap (*Botany*). The dried tuberculated roots of *Ipomæa purga* (order, *Convolvulaceæ*), imported from Mexico, are the source of the purgative resin JALAP.

Jamb (*Build.*) (1) The brickwork on each side of a fireplace. (2) The sides of a door or window opening.

Jambe *or* **Gamb** (*Her.*) The paw and part of a leg of any animal. If extending only to the first joint it is called a PAW.

Jamb, Jambart, Jambeau (*Arm.*) A defence for the leg, generally made of cuir-bouilli until the fifteenth century, subsequently of iron. *See* BAINBERGS, ARMOUR, *and* GREAVES.

Jamb Lining (*Carp. and Join.*) The wood finishings that cover the sides of window and door openings.

Jamesonite (*Min.*) A sulph-antimonide of lead, $2PbS, Sb_2S_3$. It is orthorhombic and usually occurs in very fine capillary crystals. From Cornwall, Siberia, Hungary, etc.

Japanese Paper. Made from the bark of *Morus papifera sativa*, used for expensive printing, and especially for printing proofs of engravings and etchings.

Japanners' Gold Size (*Dec.*) Size is simply a weak glue water made with gelatine of various degrees of purity, ranging from isinglass or some form of inferior gelatine which has been freed from colouring matter down to the cheapest and darkest glue. Gold size is so called from its use by gilders, and is made from very pure gelatine. Japanners use an exactly similar size.

Japanning (*Dec.*) This is a species of enamelling (*q.v.*), and, like it, is distinguished from ordinary varnishing by the japan being dried in hot stoves. Japanning, therefore, is restricted to articles of no great size, usually of metal. Japanning is done with a suitable varnish, and may be in any colour, but black is by far the commonest. Several coats of the varnish are applied for good work, and each coat is dried in the stove before the next is applied. The heat is of course much less than in enamelling, but is often as much as 150° C. The varnishes used are copals with less oil in them, but more turpentine than in an ordinary copal varnish. Japanning gives a more brilliant and a more durable surface than any ordinary varnishing can do, but costs considerably more. Tin boxes and canisters, articles of ironmongery, *papier maché* goods, slate for marble imitation, and leather are often japanned. Japan is always *coloured with mineral pigments*, on account of the heat it has to stand. The black japan owes its colour to the asphaltum from which it is made.

Japetus (*Astron.*) The most distant satellite of Saturn; distant 2,261,000 miles. Period 79d. 7h. 54m. Discovered by Cassini in 1671.

Jardinière. A vase or stand for the display of growing flowers, either inside or outside a house; also for the display of cut flowers as a table decoration.

Jargoon (*Min.*) A variety of ZIRCON (*q.v.*) of a smoky colour. Used as a gem.

Jar, Leyden (*Elect.*) *See* LEYDEN JAR.

Jarrah. *See* WOODS.

Jasmine *or* **Jasminum** (*Botany*). A genus of fragrant flowered plants belonging to the *Oleaceæ* (Olive order). The flowers of *J. officinale* and *J. grandiflorum* yield on distillation a volatile oil used in perfumery.

Jasper (*Min.*) An opaque coloured variety of silica in the massive state. It is really an intimate mixture of the crystalline anhydrous silica Quartzine and the amorphous hydrated silica Opal, together with other impurities. Of all colours, chiefly red, yellow, and green. Often found in veins in volcanic rocks, or as pebbles from the erosion of these veins. Of very wide distribution.

Jatropha (*Botany*). A genus of the *Euphorbiaceæ* found in tropical countries. The seeds of several species yield by pressure oils used medicinally, for burning, and to adulterate croton oil.

Javelin (*Arms*). A light spear used as a missile by both horse and foot in the Middle Ages. It is still carried in this country for display, *e.g.* by the footmen attending a judge on State occasions.

Jaw (*Eng., etc.*) The part of a vice, clamp, chuck, etc., which actually comes in contact with the piece of work to be held.

Jazerant (*Arm.*) Light armour composed of overlapping pieces of steel fastened by one edge to some fabric. Used in the fourteenth and fifteenth centuries in place of heavy chain or plate armour.

Jemmy. A short crowbar.

Jerkin (*Cost.*) A short jacket something like a doublet, worn by men in the sixteenth and seventeenth centuries.

Jesses (*Her.*) *See* HAWK BELLS AND JESSES.

Jet. (1) A fine stream of fluid; (2) the nozzle or pipe from which such a stream issues, *e.g.* the nozzle from which gas issues for burning.

—— (*Min.*) A hydrocarbon compound allied to Cannel Coal in composition. It is light, and takes a good polish, and hence is used for ornamental purposes. Chiefly from Whitby.

Jet Condenser (*Eng.*) The device used for condensing the steam in the older type of steam engines. The exhaust steam escapes into a space in which it mingles with cold water issuing from a jet or nozzle. The condensed steam and the water are removed by a pump, often termed an Air Pump. *See* AIR PUMP (*Eng.*)

Jets (*Astron.*) Meteoric vapours ejected from the coma of a comet towards the sun, and immediately driven back by the solar repulsion.

Jetty (*Architect.*) A portion of a building extending beyond the face of the part below, as in the case of a projecting upper storey in a half-timber building.

—— (*Civil Eng.*) A small pier or landing stage.

Jeux d'Anches (*Music*). The French term for reed stops on an organ.

Jewels. *See* PRECIOUS STONES.

Jeyes' Disinfectant. *See* CREOSOTE.

Jib (*Eng.*) The projecting part of a crane from the end of which the chain hangs down. *See also* CRANES.

—— (*Eng., etc.*) An alternative spelling of GIB (*q.v.*)

Jib Cranes (*Eng.*) *See* CRANES.

Jib Door (*Joinery*). A secret door which, when shut, resembles the wall in which it is fixed.

Jig (*Cycle Manufac.*) A device for holding parts of cycles (*e.g.* frames) in their proper relative positions while they are being operated on by hand or otherwise.

—— *or* **Jigger** (*Mining*). An appliance for sorting or dressing ore worked either by hand or by machinery.

—— *or* **Jigger Saw** (*Carp., etc.*) A narrow saw having a reciprocating motion, actuated by mechanism. Most of the work for which this saw was used is now carried out by the band saw (*q.v.*)

Jigger. A term for many mechanical contrivances used in various trades; *e.g.* in pottery manufacture, a vertical lathe upon which are made plates, saucers, dishes, and other flat and pressed wares. *See also* JIG.

Jil Barrow (*Eng.*) A flat wheelbarrow without sides, used in foundries and engineering shops.

Job (*Print.*) Work which occupies less than a sheet.

—— (*Trades*). (1) Any kind of odd work. (2) A small contract.

Jobbing Founts (*Typog.*) Types suitable for jobbing work (*q.v.*); generally of a fancy character.

Jobbing Machines (*Print.*) Small platen machines, worked either by a pedal or by power; used for jobbing work.

Jobbing Work (*Typog.*) This includes all kinds of small work, such as cards, programmes, memorandums, circulars, bills, etc.

Job's Tears (*Botany*). A grass, *Coix lachryma* (order, *Gramineæ*), belonging to China and India, grown as a cereal in Northern India. The hard "seeds" are used for ornaments, being made into necklaces, etc.

Joggle (*Carp.*) A simple joint formed by notching two pieces of timber at a point where they cross each other; *e.g.* rafters may be joggled to the purlins on which they lie.

—— (*Eng.*) A small projection on a piece of metal work, which fits into a corresponding socket on another part for the purpose of checking lateral motion.

Joggled Joint (*Masonry*). A projection formed on one stone to fit into another.

Joiner's Cramp. A long piece of T or bar iron, with a movable shoe at one end and a screw press at the other. Used for squeezing up the shoulders of tenons in doors, etc.

Joinery. The branch of wood working which deals with the more finished and ornamental parts of a building, such as doors, windows, staircases, internal fittings and fixtures; also certain classes of furniture and many articles constructed in a well finished style. *Cf.* CABINETMAKING *and* CARPENTRY.

Joint (*Bind.*) The part of the cover where it joins the back of the book on the inside, and where a kind of hinge is formed. In whole-bound books the joints are generally formed of the same material (pared down) as the cover; in half-bound books the joints are sometimes covered with cloth if the book is likely to be much used. In other cases the joints are simply covered over with the end papers, which are pasted well down into the joints.

—— (*Elect. Eng.*) The main essentials of a good electrical joint are three: (1) Electrical conductivity. (2) Mechanical strength and durability. (3) Facility for insulation. A joint may be soldered, brazed, or welded, or may be "dry," *i.e.* the two parts of the conductor are brought into close metallic contact and kept in position by twisting, lapping with wire, by a clamp, etc.

Jointing (*Carp. and Joinery*). (1) The making of various joints. *See* TENON, DOVETAIL, *etc.* (2) The truing up of large members of a structure in which considerable accuracy is required.

—— (*Eng.*) Applied to a great variety of operations, such as the connecting together of lengths of piping. In foundry work jointing means the formation of suitable surfaces on two parts of a mould which have to be separated when the pattern is withdrawn; such surfaces are usually faced with fine sand.

—— *or* **Jointer Plane** (*Joinery*). The largest form of plane, resembling a jack or trying plane in form, but 28 or 30 in. long. Used in truing up large pieces of timber.

Joints (*Carp. and Joinery*). *See* DOVETAIL, HALVING, LAP JOINT, MORTICE AND TENON, *etc.*

—— (*Geol.*) Divisional planes of secondary origin, formed in various rocks at or near the time of their consolidation. Joints usually occur in two or more transverse sets, which cut across the bedding planes of the rocks in such a manner as to divide them up into masses with some approach to geometrical regularity. They are spaced at about equal distances apart, and the rock affected does not usually tend to split between them in directions parallel to the joints. This feature distinguishes joints from cleavage. Except in the case of strata of very uniform lithological character, joints tend to a "bonded" arrangement, like that of masonry or brickwork. The joints formed in rocks which have cooled from a state of fusion generally traverse them in such a manner as to divide the eruptive rock into polygonal prisms, whose axes are perpendicular to the surface of cooling.

Joists (*Eng., Build., etc.*) A general term for beams and girders, especially the horizontal beams which carry the floors in a building. *See also* FLOORS *and* ROOFS.

Jolley (*Pot.*) A machine used in the manufacture by machinery of cups, jugs, and hollow ware generally.

Joule (*Phys.*) A unit of work equal to ten million (10^7) ergs. It is occasionally used in electrical calculations; but the unit of POWER, which is one joule per second, is more frequently required. This unit of power is termed the WATT (*q.v.*)

Joule's Equivalent, J. (*Heat*). The amount of mechanical work which can be obtained from one unit of heat if entirely converted into work; also termed the MECHANICAL EQUIVALENT OF HEAT. The value of this equivalent has been the subject of many experiments since those of Joule; it is found that one calorie is equivalent to $4{\cdot}189 \times 10^7$ ergs, or that the heat required to raise 1 lb. of water through 1° Fahrenheit is equivalent to 778 foot pounds.

Joule's Law (*Elect.*) The heat produced by a current in a conductor is proportional to the time during which it flows, the resistance of the conductor, and to the square of the strength of the current. If C be the strength of the current in ampères, t the time in seconds, R the resistance of the conductor in ohms, and H the amount of heat produced in calories, then $H = C^2Rt \times {\cdot}24$.

Journal (*Eng.*) The part of a shaft which is actually in contact with the bearings. It must be truly cylindrical, and it is often of smaller diameter than the rest of the shaft.

Journeyman. A qualified mechanic or workman.

—— (*Clocks*). *See* INDICATOR DIALS.

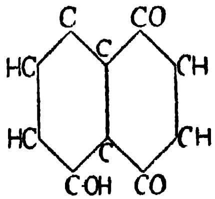
Joy's Valve Gear (*Eng.*) A set of levers forming what is termed Radial Gear, sometimes used instead of eccentrics to actuate the slide valves of a locomotive. The levers are driven by a link attached to the connecting rod.

Jubé (*Architect.*) The rood loft over the screen which separates the chancel from the nave. So named from the fact that the priest pronounced the words *jube domine benedicere* from the rood loft previous to reading the lessons. *See* ROOD SCREEN.

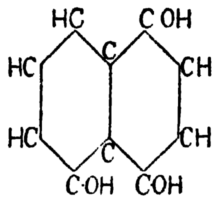
Judge (*Mining*). A measuring rod or staff used in mines.

Juglandaceæ (*Botany*). An order of Dicotyledons belonging to north temperate and tropical Asia. The Walnut (*Juglans regia*) is the best known genus, and is valued not only for its fruit, but also for its wood and an oil expressed from the seeds.

Juglone (*Chem.*)



(5-oxy-α-naphthoquinone). Garnet red needles (from alcohol); melts with decomposition at 150°. Soluble in chloroform, less soluble in alcohol. The powder causes sneezing. It is obtained from walnut shells. On reduction it gives α-hydrojuglone,



which forms colourless plates, melts at 169°, is sparingly soluble in water, readily in alcohol and ether; its solution is oxidised on standing in air to juglone. α-Hydrojuglone is poisonous. On distillation it is changed to the isomeric β-hydrojuglone. The hydrojuglones occur in unripe walnut shells.

Julian Calendar (*Astron.*) The calendar as revised by Julius Cæsar, B.C. 45. It is still, with trifling modification, used by all civilised nations

Julian Period (*Astron.*) The Julian period consists of 7,980 Julian years, each containing exactly 365¼ days. Its starting point or epoch is January 1, 4713 B.C.

Jumper (*Mining*). A form of hand drill shaped like a straight crowbar. It has a chisel-like cutting edge, and cuts a hole by a simple rising and falling motion. The blow may be intensified by striking the head of the tool with a hammer.

—— *or* **Through Stone** (*Build.*) *See* THROUGH STONE.

Jumping Up (*Forge*). Thickening the end of an iron rod by hammering it in the direction of its length; also termed UPSETTING.

Jump Joint (*Eng.*) A BUTT JOINT (*q.v.*)

Juncaceæ (*Botany*). A Monocotyledon order found in moist places in temperate and cold climates. The RUSHES (*Juncus*) are used for making baskets and similar articles, and some species are used as fodder.

Junctions (*Civil Eng.*) A point where a branch enters or leaves another line. The main rail is furnished with gaps, and the branch rail has SWITCHES or POINTS (*q.v.*) and CROSSINGS or GUARD RAILS.

Juniper (*Botany*). An oil is distilled from the unripe fruits of *Juniperus communis* (order, *Coniferæ*) and used in medicine. The fruits are also used in making gin. *See also* WOODS.

Junk Ring (*Eng.*) A cast iron ring fixed to a piston in order to squeeze the packing (*q.v.*) into close contact with the sides of the cylinder.

Juno (*Astron.*) One of the larger minor planets or asteroids discovered by Harding in 1804.

Jupiter, Planet (*Astron.*) Distance from Sun, 483,000,000 miles; diameter, 86,500 miles; periodic time, 11·86 years. Five satellites, whose periods are respectively 1d. 18½h., 3d. 13¼h., 7d. 4h., and 16d. 18h; the period of the innermost satellite is not yet accurately known.

Jupon (*Cost.*) A close fitting tunic, originally worn by knights under the hauberk or cuirass: later a sleeveless surcoat reaching to the hips, often of rich material blazoned with arms, and worn over armour. That of the Black Prince is still to be seen in Westminster Abbey. *See* COAT ARMOUR.

Jurassic System (*Geol.*) The group of rocks which embraces all the strata between the top of the Rhætic Beds (*q.v.*) and the base of the Neocomian Rocks. It therefore includes the Lias and the Oolites. These rocks are typically developed in the Swiss Jura, whence the name.

Justification (*Typog.*) The adjustment or even spacing of words and lines in a given measure.

Jute (*Botany*). The plant *Corchorus capsularis* (order, *Tiliaceæ*): also *C. olitorius* is the source of JUTE or GUNNY, which is obtained by maceration of the bast fibres, as in flax and hemp. Used in the manufacture of sacks, paper, carpets, cordage, etc.

K (*Elect.*) A symbol used for the SPECIFIC INDUCTIVE CAPACITY of a dielectric (*q.v.*)

—— (*Phys., etc.*) A symbol often used for the MOMENT OF INERTIA (*q.v.*) The letter I is also used.

k (*Elect.*) A symbol used for the MAGNETIC SUSCEPTIBILITY (*q.v.*) of iron and steel. Its value is easily obtained from the tables of PERMEABILITY (*q.v.*) by the formula

$$\mu = 1 + 4\pi k$$

in which μ equals the Permeability. It is evident that if μ be large, k is very approximately equal to μ divided by 4π or 12·5.

—— (*Phys., etc.*) A symbol frequently used to denote a constant.

Kaaba. *See* CAABA.

Kachin (*Photo.*) The name of a substance used as a developer. It is a white crystalline powder readily soluble in water. The use of bromide with this developer is unnecessary, and in fact greatly retards its action. With plates that have been considerably over-exposed it will yield good negatives.

Kahnisin (*Meteorol.*) The hot winds of Egypt.

Kakemono (*Art*). The name given by the Japanese to a wall picture, generally painted on silk or paper, and mounted on rollers. It is the custom in Japanese houses to roll up the kakemonos periodically and substitute others in their places.

Kale (*Botany*). A cultivated form of *Brassica oleracea* (order, *Cruciferæ*), used as a vegetable.

Kaleidoscope. An optical toy, consisting of a tubular body containing two (or three) mirrors arranged at angles of 60°. Small objects (*e.g.* pieces of coloured glass, beads, etc.) are contained in a glass compartment at one end; on looking through the other end, the objects and their reflection in the mirrors form symmetrical patterns, which change as the instrument is rotated. It is employed to a small extent by designers.

Kalinite (*Min.*) *See* ALUM.

Kampylite (*Min.*) A variety of MIMETITE (*q.v.*) occurring in barrel shaped crystals, whence the name. Found at Dry Gill Mine in Cumberland.

Kann (*Mining*). A Cornish name for FLUORSPAR (*q.v.*)

Kaolin (*Geol.*) Another name for CHINA CLAY. It originates chiefly through the prolonged action of subterranean waters upon felspar—chiefly upon the potash felspars Orthoclase and Microcline. As a rule kaolin occurs only in those granite areas whose surfaces have not been lately beneath the sea and which have not been recently pared to any great depth by glacial action. Kaolin is almost absent from the north of England and from the whole of Scotland. Most clays were originally impure forms of kaolin. It is a hydrous silicate of aluminium, $2H_2O . Al_2O_3 . 2SiO_2$. Approximate composition, silica = 46·3, alumina = 39·8, water = 13·9 per cent. Monosymmetric. The crystals are microscopic plates; it appears to the naked eye as a fine white clay, with a slightly soapy feel. From Cornwall, Saxony, Austria, China, and the United States. It is used with *Petuntse*, a similar material, to form hard paste porcelain. *See* POTTERY AND PORCELAIN *and* CHINA CLAY.

Karri. *See* WOODS.

Karrusel (*Watches*). A modern form of tourbillon invented by B. Bonniksen, in which the rotary escapement carriage turns at a much slower rate than in Breguet's original invention, making the watch stronger and cheaper, while gaining the same object *See* TOURBILLON.

Kaspine Leather. A new kind of white leather tanned by means of formaldehyde and an alkali. The process was discovered by E. E. M. Payne in 1898.

Kater's Pendulum. *See* PENDULUMS.

Kathode *or* **Cathode** (*Elect.*) The conductor or electrode (*q.v.*) by which an electric current leaves a conducting system, *e.g.* a liquid or gas.

Kathode Rays (*Elect.*) An emanation from the kathode in a highly exhausted vacuum tube. These rays probably consist of a stream of negatively electrified particles, shot out from the kathode: they travel through the stream in straight lines, and can be deflected or even brought to a focus by a plate of suitable shape placed in their path; they are also deflected by a magnet. They are either identical with or give rise to the emanation known as LENARD RAYS (*q.v.*) *See also* RADIATION.

Kation *or* **Cation** (*Elect.*) The ION (*q.v.*) in a solution, which travels towards the KATHODE (*q.v.*)

Kauri. *See* WOODS.

—— (*Dec.*) Kauri or Cowrie copal is a resin exuded by two trees, *Dammara australis* in New Zealand, and *D. ovata* in New Caledonia. It is used for varnish making. In commerce the only kauri used is the sub-fossil exudation, which is dug up in lumps, often weighing a hundredweight or more. The fresh exudation of the trees is of no value. The value of kauri in varnish making is due to the large amount of oil it will take up, and to the fact that it can be worked into a varnish at a lower temperature than any other copal. The trade in it amounts to about half a million pounds sterling per annum.

Kazen (*Mining*). A Cornish term for a sieve.

Keel Moulding (*Architect.*) A moulding used in the Early English and Decorated periods. In section it resembles the keel of a ship or an ogee arch. It consists of a pointed bowtell with a slight sinking on each side of the point or arris. *See* BOWTELL, ROLL MOULDING, *and* SCROLL MOULDING.

Keen's Cement (*Build.*) A cement or plaster capable of being worked to a very hard and highly polished surface. It is obtained by soaking plaster of Paris in alum water after a first calcination; it is then put again into the kiln, reburnt, and ground. It is especially useful on sharp angles of walls and on walls which have to be painted.

Keep (*Archæol.*) *See* DONJON.

Keeper (*Elect.*) A piece of soft iron placed across the poles of magnets; it completes the magnetic circuit and decreases the demagnetising effect.

—— (*Eng.*) The lower part of the bearing in the axle box of a railway vehicle; there is no force exerted by the axle on this part of the bearing during steady running.

Kefir (*Foods*). *See* KEPHIR.

Kelp (*Chem.*) The ash obtained by burning seaweed, especially deep-sea weed. It is used in the preparation of iodine (*q.v.*) Instead of burning it, the weed may be extracted with sodium carbonate solution, and the liquid obtained treated with hydrochloric acid. The resulting liquid, neutralised with caustic soda and evaporated, gives a residue of salts called kelp substitute; it contains all the iodine, and is used for the preparation of iodine.

Kelp Substitute (*Chem.*) *See* KELP.

Kentish Coal. *See* COAL.

Kentish Rag (*Build.*) A stone used for rubble walling. *See* BUILDING STONES.

Kentledge (*Eng.*) The heavy material (stones, scrap iron, etc.) used to form a counterbalance weight in a balance crane.

Kephir *or* **Kefir** (*Hygiene*). Fermented cow's milk; a modern substitute for KOUMISS (*q.v.*) It is more easily digested and absorbed than the original milk, and is used medicinally. The process of fermentation is a double one; both lactic acid (*q.v.*) and alcohol are produced, though the amount of each is very small.

Kepler's Laws (*Astron.*) FIRST LAW: The orbit of a planet is an ellipse, the sun being in one focus. SECOND LAW: The radius vector (the line joining the sun to the planet) sweeps out equal areas in equal times. THIRD LAW: The squares of the Periodic Times of the planets are proportional to the cubes of their mean distances from the sun.

Kerargyrite (*Min.*) A synonym for HORN SILVER (*q.v.*)

Keratin (*Zool.*) An organic substance which is found in horn, nails, and in the cells of the epidermis when it assumes a horny texture, *i.e.* when pressed out by the growth of younger cells.

Kerf (*Carp. and Join.*) The cut made by a saw.

Kermesite (*Min.*) An oxysulphide of antimony, $2Sb_2S_3$, Sb_2O_3. Antimony = 76·34, oxygen = 4·73, sulphur = 18·93 per cent. Monosymmetric. Crystals usually acicular. Also in radiating masses. Saxony Bohemia, Hungary, France, etc.

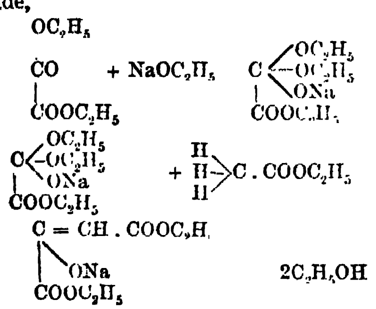
Kern (*Typog.*) That part of a letter which overhangs its body or shank, more generally met with in italic type, owing to the slope of the characters.

Kerr's Phenomena *or* **Kerr Effects** (*Phys.*) Kerr discovered that a transparent dielectric like glass or carbon disulphide becomes doubly refracting under the influence of an electrostatic strain. Terminals were fixed in holes drilled in a slab of glass and connected to a powerful electric machine, and the glass was placed between crossed Nicol prisms, so that the light passed through it at right angles to the lines of electric force. On working the machine the dark field became coloured. Kerr afterwards discovered a magnetic effect on polarised light. When plane polarised light is reflected from the polished surface of the pole of a powerful magnet, the plane of polarisation is rotated: the rotation produced by a positive pole is in a clockwise direction; that produced by a negative pole is in the reverse direction. The phenomena is, however, complicated, and depends upon the relation of the plane of polarisation to the plane of incidence. This effect is one of the various experimental results which connect light with electro-magnetic phenomena.

Kerosene (*Chem.*) That fraction of American petroleum boiling between 150° and 300°, and consisting of paraffin hydrocarbons (*q.v.*) containing from 10 to 16 atoms of carbon. It is usually purified by shaking in succession with sulphuric acid and caustic soda, distilling it, and collecting for burning purposes the fraction coming over between the above temperatures.

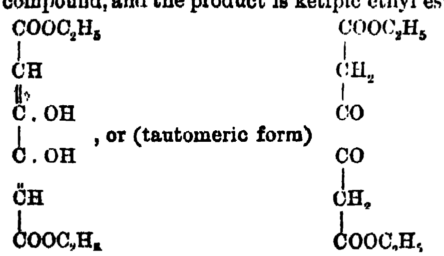
Ketipic Acid (*Chem.*) *See* KETIPIC ESTER.

Ketipic Ethyl Ester (*Chem.*)
$$\begin{array}{l}COCH_2COOC_2H_5\\ |\\ COCH_2COOC_2H_5\end{array}$$
A crystalline solid; melts at 77°, soluble in alcohol. Ferric chloride imparts a deep red colour to its solution in alcohol. Forms an osazone (*q.v.*) On hydrolysis it yields the unstable ketipic acid, which readily loses $2CO_2$ and forms diacetyl—a diketone (*q.v.*) Ketipic ethyl ester is obtained as follows: Act upon ethyl oxalate and ethyl acetate with sodium ethoxide,

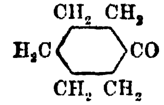


Acidify, and the product is $\begin{array}{l}C.OH : CH.COOC_2H_5\\ |\\ COOC_2H_5\end{array}$

(ethyl oxalacetate). Repeat the whole process on this compound, and the product is ketipic ethyl ester,

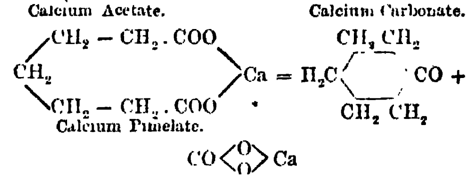


Ketones (*Chem.*) Compounds of the formula $R - CO - R'$, where R and R′ are alkyl groups or other hydrocarbon residues which may be the same or different, are called ketones. Examples are acetone CH_3COCH_3, and acetophenone $CH_3COC_6H_5$. When R and R′ are substituted alkyls or hydrocarbon residues, the compounds have still the ketone character, but have also the character of the substituting groups superimposed on the ketone character; *e.g.* ethyl acetoacetate, $CH_3CO.CH_2COOC_2H_5$, has the ketone character, but this is modified by the presence of the group $-COOC_2H_5$. The ketone group may also occur in a ring, giving rise to what are called cyclic ketones; *e.g.*



which is called cyclohexanone (*see* NOMENCLATURE) or ketohexamethylene. The ketone group may occur more than once in a compound, giving diketones (*q.v.*), etc. Among the benzene compounds there occurs a class of ketones of such distinctive properties that they have been given a special name—quinones (*see* QUINONES). The ketones may be obtained by many methods; *e.g.* (1) Heating the calcium salts of acids—

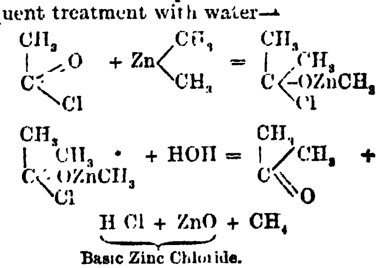
$$\begin{matrix}CH_3COO\\ CH_3COO\end{matrix}\!\!>Ca = CH_3COCH_3 + CO\!<\!\begin{matrix}O\\ O\end{matrix}\!>Ca$$
Calcium Acetate. Calcium Carbonate.



(2) Oxidation of a secondary alcohol—

$$CH_3.CHOH.CH_3 + O = CH_3.CO\ CH_3 + H_2O$$
Secondary Propyl Alcohol.

(3) Action of zinc alkyls on acid chlorides and subsequent treatment with water—



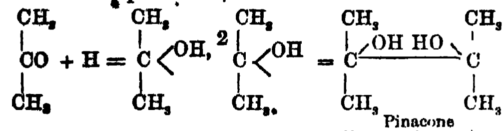
(4) From nitriles by the action of an alkyl iodide in presence of magnesium, the best yields being obtained with aromatic nitriles (*e.g.* benzonitrile with ethyl iodide gives an 80 per cent. yield of the ketone)—

$$C_6H_5CN + C_2H_5I + Mg = \begin{matrix}C_6H_5\\ C_2H_5\end{matrix}\!\!>C = N.MgI$$
Benzonitrile.

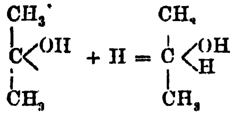
$$2\begin{matrix}C_6H_5\\ C_2H_5\end{matrix}\!\!>C : NMgI + 4HOH = 2\begin{matrix}C_6H_5\\ C_2H_5\end{matrix}\!\!>CO +$$
$$2\,NH_3 + Mg\,(OH)_2 + MgI_2$$

(5) From β-ketonic acids by hydrolysis of the ester by alcoholic caustic potash (*see* ETHYL ACETOACETATE). Important examples of ketones are acetone, acetophenone, camphor; and of com-

pounds containing ketone groups, ethyl acetoacetate and lævulose (*see these*). (6) Aromatic ketones may be obtained from benzene by the action of an acid chloride in presence of aluminium chloride (*see* ACETOPHENONE). The chemical reactions of the ketones are : (1) On reduction they yield secondary alcohols and pinacones,



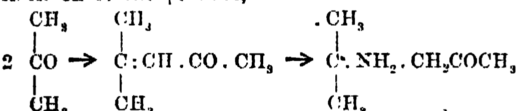
Pinacone
Tetramethylglycol.



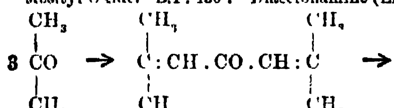
(2) On oxidation they yield acids with a smaller number of carbon atoms in the molecule than the original ketone; *e.g.* ethyl propyl ketone, $CH_3CH_2COCH_2CH_2CH_3$, yields acetic, propionic, and butyric acids. (3) Phosphorus pentachloride replaces the oxygen by two atoms of chlorine,

$$CH_3COCH_3 \rightarrow CH_3CCl_2CH_3$$

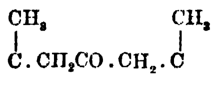
(4) Ammonia causes condensation, and then adds itself on to the product,



Mesityl Oxide. B.P. 130°. Diacetonamine (Liquid).

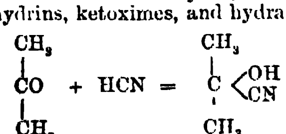


Phorone. M.P. 28°.

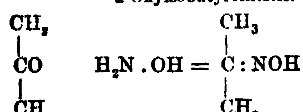


Triacetonamine. M.P. 40°

(5) With hydrocyanic acid (HCN), hydroxylamine (H_2NOH), and phenylhydrazine ($H_2N.NHC_6H_5$) the ketones behave like the aldehydes, forming respectively cyanhydrins, ketoximes, and hydrazones—

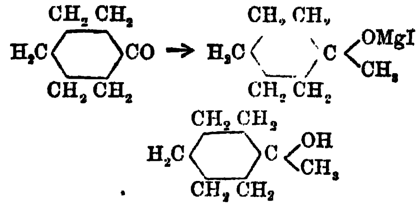


a-Oxyisobutyronitrile. B.P. 120°.



Acetoxime. M.P. 60°.

(6) Those ketones which contain a methyl group unite directly with sodium hydrogen sulphite just as the aldehydes do. (7) Ketones undergo condensation; *e.g.* hydrochloric acid causes two molecules of acetone to lose one molecule of water and form mesityl oxide (*see* 4); three molecules of acetone to lose two molecules of water and form phorone (*see* 4). Boiled with sulphuric acid, acetone condenses to mesitylene (*q.v.*) (8) Ketones, especially cyclic ketones, yield tertiary alcohols when boiled with magnesium and an alkyl iodide in ethereal solution, and the product of the reaction acidified with dilute acid :



Ketose (*Chem.*) A sugar which contains the ketone group is called a ketose—*e.g.* lævuolose (*q.v.*)

Ketoximes (*Chem.*) *See* KETONES, *also* OXIMES.

Kettledrums (*Music*). *See* MUSICAL INSTRUMENTS (PERCUSSION).

Kettlestitch (*Bind.*) The chain stitch made at the head and tail of a book when the sections are being sewn together, prior to binding, in order to keep them firm.

Keuper (*Geol.*) The uppermost division of the Trias or Upper New Red. In Britain it consists of a small thickness of sandstone, prevalently red in colour, and an overlying series of red marls, which range to as much as eight hundred feet in thickness where they are most fully developed. Deposits of rock salt, and also of gypsum, occur in these marls. The Keuper series has been formed under continental conditions, and in an arid climate, at the bottom of inland lakes.

Key (*Bind.*) A small metal implement used to secure one end of a band to the base of a sewing press, the other end being attached to a loop formed of cord on the adjustable bar running across the press. *See* BANDS; *and* SEWING PRESS *under* BOOKBINDING.

—— (*Eng., etc.*) (1) A wedge shaped piece of iron or other material used for fixing a joint, especially the wedge by which a wheel is fixed on its axle. (2) A tool used for turning a nut or other loose part of some machine or structure.

—— (*Music*). I. A system of notes in connection with one certain note called the "Tonic," or keynote, from which the key is named. This system includes the seven notes of the major diatonic scale, together with five chromatic notes, *viz.* the flattened 2nd, 3rd, 6th, and 7th, and sharpened 4th of the diatonic scale. The technical names of the seven diatonic notes are : (1) Tonic or keynote. (2) Supertonic (above the tonic). (3) Mediant (midway between tonic and dominant). (4) Sub-dominant (the *under*-dominant, being a fifth below the tonic just as the dominant is a fifth above the tonic) (5) Dominant (governing note). (6) Sub-mediant (the *under*-mediant, being midway between the sub-dominant (under-dominant) and the tonic. (7) The leading note (from its tendency to lead to the tonic, below which it is only a semitone), also called sub-tonic (under the tonic). [8. Tonic or keynote, being replicate of 1.] Starting from C, the twelve notes of the key are :

These notes with the tails turned down form the major scale; those with the tails turned up, the minor scale. The whole series form the diatonic chromatic scale. II. That part of the mechanism of keyed instruments on which the finger rests. It is, strictly speaking, a lever, which in the case of the pianoforte raises a hammer, and in the case of the flute, etc., opens or closes the sound holes.

Key (*Plastering*). The portion of the plaster that squeezes through the laths of a ceiling or partition; any holes or roughness that the plaster can hang to.

Key Bed *or* **Way** (*Eng.*) The grove cut in a shaft or the hub of a wheel, into which the key is driven.

Keyboard (*Music*). The set of keys on instruments played by means of keys. On organs the keyboards are spoken of as "manuals," to distinguish them from the keyboard played with the feet, called a pedal board.

Key Harmonica (*Music*). *See* MUSICAL INSTRUMENTS (PERCUSSION).

Keyhole Saw (*Carp.*) A narrow saw having a handle at one end only, and somewhat resembling a very narrow handsaw; used for cutting out small pieces of wood such as those removed in forming the central part of a keyhole. A hole is bored at each end of the keyhole, in which the point of the saw can be inserted.

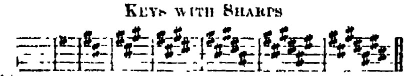
Keyless Work (*Watches*). The mechanism enabling one to wind and set a watch by turning the pendant knob or "button," instead of having to use a separate key.

Keynote (*Music*). *Also called* TONIC. The note from which the scale begins, and by which it is named.

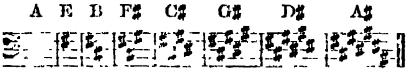
Key Seating (*Eng.*) A KEY BED (*q.v.*)

Key Signature (*Music.*) The sharps or flats belonging to the key placed at the beginning of a piece of music between the clef and the time signature to show that every note of their respective names, throughout the piece, is to be so affected unless contradicted. The sharps and flats are called ESSENTIAL sharps and flats, and are written as follows:

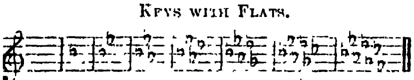
KEYS WITH SHARPS



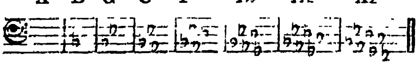
Major Key.	C	G	D	A	E	B	F♯	C♯
Minor Key.	A	E	B	F♯	C♯	G♯	D♯	A♯



KEYS WITH FLATS.



Major Key.	C	F	B♭	E♭	A♭	D♭	G♭	C♭
Minor Key.	A	D	G	C	F	B♭	E♭	A♭



It will be seen that in keys with sharps the major keynote is always one note above the last sharp in the signature, and in keys with flats it is always the last flat but one in the signature. The keys of C major and A minor having no sharp nor flat are often spoken of as the "open" signature. It will be noticed that the minor keynote is always three semitones below the major keynote. A simple rule to determine whether a piece is in the major or minor key is: Assume that it is major, then see if the dominant is unaltered throughout the piece or section. If unaltered, it is major; but if that note be raised in the majority of times it occurs, then it is in the minor key.

Keystone (*Architect.*) The stone which occupies the centre of the crown of an arch. *See* ARCH.

Kibble, Kibbal (*Mining*). A vessel used for drawing up materials from a mine; a bucket, barrel, etc.

Kick (*Build.*) The depression or FROG in the surface of certain kinds of bricks.

Kidney Ore (*Min.*) A variety of HÆMATITE (*q.v.*) so called from its resemblance to a lobed kidney.

Kieselguhr. A fossil deposit consisting of the silicified valves of the vegetable organisms known as DIATOMS (*q.v.*) It is used in making dynamite (*q.v.*)

Kieselguhr Bricks. *See* BRICKS.

Killas (*Geol.*) A Cornish name for the country rock, mainly of sedimentary origin, in which the metalliferous veins occur. The name is applied irrespective of the geological age of the rock. A large part of the killas may be of Devonian age; some is certainly Carboniferous; and part may pertain to the Proterozoic System. Most of the "killas" of Devonshire and Cornwall has been dynamically metamorphised.

Killed Spirits. A solution of zinc chloride used in soldering; scrap zinc is added to hydrochloric acid until the acid is neutralised or "killed."

Kiln. A furnace in which ore or some other substance is placed in order to be strongly heated, but not fused; *e.g.* in glass manufacture a square or rectangular annealing oven heated on both sides, used chiefly for annealing large articles. When full the kiln is closed, and by allowing the fires gradually to become extinct, the articles are more thoroughly annealed than by passing them down the lear. *See* BRICKS, GLASS MANUFACTURE, POTTERY AND PORCELAIN, BISQUE OVEN, GLOST OVEN, ENAMEL KILN, *etc.*

Kilogram. *See* WEIGHTS AND MEASURES.

Kilometre. *See* WEIGHTS AND MEASURES.

Kinematics. The science dealing with the motion of bodies, apart from the forces which produce the motion.

Kinetic Energy. The energy which a body possesses in virtue of its motion. If m be the mass, and v the linear velocity of a body, then the kinetic energy is $\frac{1}{2} m v^2$. In the case of a rotating body, if K be its MOMENT OF INERTIA (*q.v.*) and ω its angular velocity, the kinetic energy is $\frac{1}{2} K \omega^2$.

Kinetic Friction. *See* FRICTION, KINETIC.

Kinetic Theory of Gases (*Phys.*) The theory whereby the known physical properties of gases are deduced from the assumption that a gas consists of many separate molecules, each having a finite mass and velocity, and obeying the ordinary laws of motion.

King Bolt (*Carp and Join.*) An iron rod, taking the place of the king post in a truss. *See also* ROOFS.

Kingcloser. A brick cut lengthwise, showing $2\frac{1}{4}$ in. one end and $4\frac{1}{2}$ in. the other.

King Post (*Carp. and Join.*) The central vertical timber in a trussed roof or in a partition. *See also* ROOFS.

King Rod (*Build.*) An iron rod used in place of the king post in an iron roof. *See* KING BOLT *and* ROOFS.

Kings of Arms. The chief officers of the Heralds' College. They are "Garter," "Clarenceux," and "Norroy" for England; "Bath," "Lyon," and "Ulster" for Wales, Scotland, and Ireland respectively.

Kino. A dark red astringent jelly-like juice used in medicine and tanning. Obtained from incisions made in the trunks of various trees and shrubs in tropical and sub-tropical regions. The chief varieties are official or Malabar Kino (India and Ceylon), and Australian or Eucalyptus Kino. It resembles CATECHU (*q.v.*).

Kiosk *or* **Kiosque** (*Architect.*) A small structure, generally polygonal or circular in construction, with open sides, and surmounted by a dome-shaped or tent-shaped roof carried on pillars. Used as a band stand, summer house, etc.

Kip Leather. Leather made from Kip hides, which are the skins of yearling cattle grown in India.

Kirchoff's Hypothesis (*Astron.*) The hypothesis which explained the origin of the dark lines in the solar spectrum. When the light from an incandescent body passes through the same substance in a state of vapour, the coloured bands become replaced by dark or absorption lines.

Kirchoff's Laws (*Elect.*) FIRST LAW: At a point where any number of conductors carrying currents meet, the algebraic sum of all the currents flowing towards the point is equal to the sum of the currents flowing away from the point. SECOND LAW: If any closed circuit be made up of conductors of resistance r_1, r_2, r_3, etc., and if the currents in these conductors are c_1, c_2, c_3, etc., then the algebraic sum $c_1r_1 + c_2r_2 + c_3r_3 +$ is equal to the electromotive force acting in the circuit. This law is of great use in the calculation of currents in conductors forming a number of different closed circuits, *e.g.* the WHEATSTONE BRIDGE (*q.v.*)

Kish (*Chem.*) A name given to the carbon which separates from melted pig iron when silicon or highly silicious iron is added to it. When a molten mass of grey pig iron is allowed to cool *slowly* (as in a foundry ladle) a scum of graphitic carbon (*q.v.*) separates and collects on the surface.

Kist. *See* CIST.

Kit-Cat (*Paint.*) A term applied to a portrait on canvas rather less than threequarter length (36 by 28 in.), in which the hands are shown. The term arose from the fact that Sir Godfrey Kneller painted a series of portraits of members of the *Kit-Cat Club* on canvases of those dimensions to fit the walls of a room in Tonson, the publisher and bookseller's residence, Barn Elms, Putney. Addison and Steele were amongst the members of the club.

Kitchener *or* **Kitchen Range.** A kitchen stove the grate portion of which can be either used as an open or a closed range. It is provided with an oven and a boiler and with the necessary flues for heating them. The top of the stove, known as the hot plate, is used for heating saucepans, etc.

Kite (*Meteorol.*) An instrument for "sounding," or taking observations in, the air Of various shapes and sizes. It is raised in the air by the force of the wind pressing against its surface, and is held steady by means of a cord.

Kite Winch (*Meteorol.*) A winch used for paying out the line or winding it up during the flight of a kite.

Klemm's Leather. *See* CROWN LEATHER.

Knee (*Carp. and Join.*) A convex curve, the reverse of a RAMP (*q.v.*)

Kneeler (*Build.*) A stone placed either at the base of the slope of a gable or at a higher level; its base is horizontal, while one face is usually cut to the same angle as the gable. It serves to relieve a part of the diagonal thrust.

Knib (*Typog.*) A small projection at one end of a setting rule to enable it to be more easily lifted from the composing stick when the line of type has been set.

Knife Edges. Sharp edges of steel, agate, or other hard material, on which a lever turns; used in balances, weighing machines, etc.

Knife File (*Eng.*) A thin, sharp edged file.

Knitting Frame, *or* **Loom** (*Textile Manufac.*) A machine for the knitting of warp threads into a wearable fabric. It may be a straight-bar or circular loom. The fabric possesses the same structure as that due to the ordinary process of knitting.

Knocking (*Eng.*) A noise heard in the cylinder of a pump or engine, due to a loose part or the accumulation of fluid (gas, steam, or water) at the end of the stroke. The term is often applied to noises due to various other defects in machinery.

Knocking-Down Iron (*Bind.*) An oblong rectangular piece of iron with a leg on one side, by means of which it is secured in the lying press. The upper surface, which is flat, is used as a support when beating the slips in the boards after they are laced in, so that they may be imperceptible when the boards are covered.

Knop Yarn (*Textile Manufac.*) Yarn on the surface of which are formed at intervals small knops or lumps, which may be of one or several colours. The process of producing this yarn is known as "knopping," and is done on the twisting frame.

Knots (*Her.*) Heraldic badges, made of intertwined cords, borne by different families.

Knotter (*Paper Manufac.*) An appliance for removing knots and mechanical impurities from pulp.

Knotting (*Dec.*) A preparation of shellac used for covering knots in wood before being painted. *See* HOUSE PAINTING.

Knuckle (*Build.*) The joint of a hinge.

Knuckle Joint (*Eng.*) A hinged joint between two rods; one possesses an eye or loop, fitting into a forked projection on the other rod; a pin passes through the eye, forming an axis, about which the two members can turn.

Kohlrabi (*Botany*). Like the cabbage, broccoli, and kale, this plant is a cultivated variety of *Brassica oleracea* (order, *Cruciferæ*).

Kola (*Botany*). An African plant, *Cola acuminata* (*Sterculiaceæ*), whose seeds, known as Kola nuts, are used in medicine, having the power of sustaining fatigue.

Kollergang (*Paper Manufac.*) *See* EDGE RUNNER.

Kombé (*Botany*). The important drug STROPHANTHIN is obtained from the ripe seeds of *Strophanthus kombe* (*Apocynaceæ*), which are used in Central Africa as an arrow poison.

Koumiss *or* **Kumiss**. An alcoholic beverage resulting from the fermentation of mare's milk, commonly used by many nomadic tribes in Asia, especially by the Tartars. Sometimes used dietetically in this country.

Kr (*Chem.*) The symbol for KRYPTON (*q.v.*)

Krio Sphinx (*Architect.*) A carved figure having the body of a lion and the head of a ram. *See* SPHINX *and* ANDRO SPHINX.

Krokidolite (*Min.*) *See* CROCIDOLITE.

Krypton, Kr. (*Chem.*) Atomic weight, 81·8. A gas without chemical reaction. It has a monatomic molecule; a characteristic spectrum; boils at $-151{\cdot}7^{\circ}$ It occurs in the atmosphere to the extent of 1 part in 7,000,000. It is obtained by fractional distillation of liquid air.

Kundt's Experiment (*Sound*). If a fine powder be placed in a tube containing a gas in which STATIONARY WAVES (*q.v.*) of sound are being produced, the powder collects in heaps at the LOOPS (*q.v.*); from the position of these heaps we can determine with fair accuracy the distance from one loop to the next, and hence the wave length (*q.v.*) of the sound in the gas in the tube. From the wave length we can calculate the velocity of sound in the gas.

Kupfernickel (*Min.*) Arsenide of nickel, NiAs. Nickel=44·1, arsenic=55·9 per cent. Hexagonal, but usually massive, with a coppery colour, whence the name. It is used as an ore of nickel. From Cornwall, Linlithgowshire, Wigtonshire, Saxony, Bohemia, many places in Scandinavia, N. and S. America.

Kyanising (*Eng., Build.*) Soaking timber in a solution of corrosive sublimate, $HgCl_2$, in order to preserve it.

Kyanite (*Min.*) A silicate of aluminium, Al_2O_3, SiO_2. Silica=37, alumina=63 per cent. Triclinic, occurring in bladed crystals in metamorphic rocks. Pale blue to white. Banffshire, Aberdeenshire, Perthshire, Shetland, Ireland, Switzerland, Tyrol, the United States, etc.

Kylin (*Art.*) A mythical animal often depicted on Chinese and Japanese porcelain. Sometimes known as the Chinese Unicorn.

L (*Phys.*) The symbol for LATENT HEAT (*q.v.*)

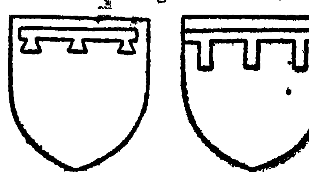
La (*Chem.*) The symbol for LANTHANUM (*q.v.*)

La, Lah (*Music*). The sol-fa name for A in the fixed Do system; and for the sixth degree of the scale (submediant) in the movable Do system.

Labarum (*Archæol.*) (1) The Roman imperial standard as altered by Constantine the Great after his conversion to Christianity, certain Christian symbols being incorporated on it. (2) A general term for a banner or standard.

Label (*Architect.*) *See* HOOD MOULD.

—— *or* **File** (*Her.*) A mark of cadency used to distinguish the eldest son during the lifetime of his father. It consists of a bar with three points placed across the paternal shield, in chief. In the case of younger sons the paternal shield is differenced by the following additions:



MODERN FORM. OLD FORM.

the second son uses a crescent; the third son a mullet; the fourth son a martlet; the fifth son an annulet; the sixth son a fleur-de-lys; the seventh son a rose; the eighth son a cross moline; the ninth son a double quatrefoil. In the case of royalty the label is employed by all sons, but the second and younger sons bear the label differenced.

Labiatæ (*Botany*). The natural order *Labiatæ* includes a large number of plants which are valued for the essential oils they contain. A common and fairly typical example is the WHITE DEAD NETTLE (*Lamium album*). Among the plants of this order are the LAVENDER (*q.v.*), SWEET BASIL (*Ocymum basilicum*), MINT (*Mentha*), MARJORAM (*Origanum*), THYME (*Thymus*), ROSEMARY (*Rosmarinus officinalis*), BALM (*Melissa*), HOREHOUND (*Marrubium*), *Pogostemon Patchouli*, which yields OIL OF PATCHOULI, and many others.

Laboratory. (1) A place in which experimental work and investigation in natural science are carried on. (2) Another term for the "hearth" of a reverberatory furnace, *i.e.* the part in which the effective work of the furnace is performed.

Labradorite (*Min.*) A calcium aluminium sodium silicate; approximate composition, silica = 52·9, alumina = 30·3, lime = 12·3, soda = 4·5 per cent. Triclinic. It is one of the felspars. Grey, brown, greenish, sometimes colourless. It shows a fine play of colour in certain directions, and is cut as an ornamental stone. It is of very wide distribution in basic volcanic rocks.

Laburnum. *See* WOODS.

Lac (*Botany*). A resinous exudation from the branches of a number of trees such as *Ficus indica* and *F. religiosa* (order, *Moraceæ*); *Butea frondosa* (order, *Leguminosæ*); *Croton lacciferus* (order, *Euphorbiaceæ*). It is caused by the punctures of a small insect (*Cossus ficus*). *See also* SHELLAC.

Laccolite (*Geol.*) A term originally applied to those occurrences of intrusive rocks in which the eruptive rock displaces its own volume of the rock invaded, and thus, as it were, lifts the whole of the overlying country rock on its back. One or two such instances have been seen abroad; but most of the intrusive masses to which this name has been applied are nothing more than sills occurring in the usual manner, *i.e.* without any such upward arching of the country rock above. The term may well be dispensed with.

Lace Hand and Machine Made. "The earlier laces were plain braids," and were made by "unroving the edges of woven material and plaiting or knotting the fringe so formed" into a reticulated border. This was one of the earliest forms of ornamentation. Further developments were the introduction of a braid with a toothed edge called DENTELLE and CUTWORK,

the latter a method of ornamentation, which was produced by arranging a series of threads upon a frame and interlacing them by the aid of needle and thread, thus forming a net or ground upon which various objects cut out of woven material could be embroidered. Every draper's shop window gives ample evidence of the survival—or revival in a modern form—of this art, by the display of a multiplicity of articles, both for home and personal adornment, composed of fabrics of the most diverse character superimposed upon each other, *e.g.* a design, worked by the aid of the sewing machine, through two fabrics. Upon the superfluous material of the imposed fabric being cut away, effects are evolved artistic, unique, or peculiar. A similar effect to cutwork was attained by the method known as DRAWNWORK, produced by drawing a design upon woven fabric and then carefully cutting certain threads of both weft and warp at regular intervals in the interspace between the various objects of the design; the cut threads were then carefully drawn out, thus leaving reticulated openwork which could afterwards be more firmly secured by the aid of the needle and to the fancy of the worker. These methods were the fashionable employment for ladies of the period about 1587. There are two descriptions of lace, "point" and "pillow." Real POINT LACE is made entirely by the aid of the needle, upon a parchment pattern, each loop or stitch being so worked as to hold the preceding stitch in position. The Italians claim to have invented it, but they probably derived the art of fine needlework, of which lace is a development, from the Greeks. Much proficiency in the art had been attained by 1626, and a great development in 1665 by Colbert's establishment of the POINTS OF FRANCE. The chief centres of manufacture were Venice, Milan, Genoa, and Brussels. The nuns also were amongst the principal makers, being very expert in the production of the extremely fine flaxen thread so essential to the making of high class lace. It is mainly owing to the fineness of this thread that BRUSSELS LACE (*q.v.*) owes its beauty of appearance. PILLOW LACE is made upon a parchment pattern, but quite a number of threads enter into its composition, each thread having a separate source of supply called a bobbin; and, being similar in shape to an ordinary lead pencil, they can be twisted or otherwise manipulated with ease. The parchment pattern being secured to the pillow or cushion and the threads to pins, stuck at suitable intervals into the cushion, the worker's hands are free to make the necessary movements. There is a considerable quantity of "lace" that is designated SEMI-REAL LACE produced by modern methods. It is a composite article, machine made braids being utilised to form the more substantial outline of the pattern, the "fillings" being wrought by the needle and also by adventitious aids. Very effective articles are produced, Luxeuil being one of the principal sources of manufacture. Most laces take their name from the place where they were first made, or that were noted for the excellence of their production, and many laces differ much more in name than in appearance. The chief exception to this rule is GUIPURE, which takes its name from a made up cord composed of some inferior material, such as cotton wrapped round or plated with a more valuable article, *e.g.* gold thread or silk. This principle produces, not only a thicker thread, but a thread of an entirely different appearance, and is used to form the raised pattern. Any lace therefore that contains raised outlines attained by this or similar methods may be called "Guipure": thus we find "Spanish Guipure," etc., and also various "made up" names as "Guipure d'art." The Germans claim the invention of pillow lace, and Barbara Uttmann, of St. Annaberge, as the medium, about 1560.—W. H.

Lace Machine. Ignoring experiments, the first machine for producing lace net as a practical and commercial success was invented by John Heathcote, 1809-11; and though many mechanical imperfections have been eliminated and improvements developed, the fundamental principle remains the same in the modern machine of to-day. The object to be attained is to twist one series of threads around a neighbouring and alternating series. This is accomplished by dividing the threads that will eventually compose the fabric into two systems, one called the "warp," where each thread has a common source of supply (the warp beam), and the other called the "bobbins," which, though numerically the same, have each an independent source of supply. The continuity of this latter system of threads is thus broken below receptacles called the "carriages," each of which contains an independent bobbin. These carriages (with the bobbins they contain) are so attenuated, so slim, that the whole system is able to pass simultaneously between neighbouring warp threads. A slight lateral movement of the warp threads at right angles to the plane of the carriages (to the right when the carriages swing in one direction, and to the left at the return movement of the carriages) causes warp thread and bobbin thread to twist together. A continuation of these movements simply forms a series of twisted pillars, composed of one bobbin and one warp thread twisted together, and having no connection with any neighbouring pair of threads; but if at certain regular intervals a more extended lateral movement is communicated to the guide bars that control the warp threads (say over two carriages instead of only one), then community is at once established and a web of net begins to be formed, the description of net being dependent upon the character of the movement communicated to the warp threads. It requires two "motions" or movements of the carriages to form one complete twist, and by reference to fig. 1 it will be readily understood that it has taken six to and fro movements of the carriages to form the first three twists represented in the upper portion of the drawing; it will also be realised that so long as this limited amount of movement is continued, only twisted pillars would be formed, as previously mentioned; but the seventh movement shows the warp thread as having been moved to the right behind two bobbin threads; the eighth movement, to the left over one bobbin; the ninth movement, to the right under one bobbin; the tenth movement, to the left over two bobbins; the eleventh movement, to the right under one

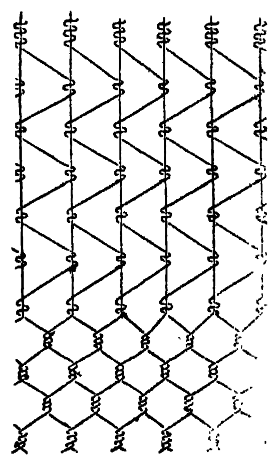


FIG. 1.

bobbin: the twelfth movement, to the left over one bobbin, after which it is all repetition in the same order. Up to this point it has been assumed that the bobbin thread is a straight line, as represented in the drawing; and on paper this is perfectly correct, but it must be remembered that the bobbin threads form a system of threads to themselves, each thread from an independent source; and the tension upon each thread is controlled by a flexible spring, that impinges upon the bobbin: these springs are adjusted to give a uniform tension, as far as possible. The warp threads (the other system) all come from a common source, and one controlling influence affects them collectively. This controlling influence generally takes the form of a cord passed around a collar on the end of the warp beam. To the end of this cord a weight or spring is attached, though other mechanical devices are used. It will be obvious that should the weight or tension upon the warp exceed that upon the bobbins, the exact reverse of what is represented in the drawing would occur—*viz.* the warp would pull straight and the bobbin would lie across. Neither of these conditions would contribute to success in net making; it is the happy medium that is required—just sufficient tension upon the warp to cause bobbin and warp to adapt themselves to each other, as shown in the last three meshes represented, which depict the formation of MECHLIN NET, also known as MALINES and TULLE. There are three descriptions of twist lace machines, but one principle obtains in them all. The principle is that of a swinging pendulum, all the machines being built to a certain diameter of circle, generally 12 to 14 in. It is in the lower half of the circumference of this circle that the carriages, properly controlled, swing, like so many pendulums, and with similar rhythm, at a speed of about 120 swings or "motions" per minute. The machine invented by John Heathcote is best adapted for making plain net, either Brussels or Mechlin. Owing to difficulties originally encountered in procuring carriages of sufficient thinness he found it necessary to place the carriages in two rows or tiers one behind the other, and though the principle was adopted in the first instance as an extremity, it was found so efficient for the making of traverse net that it has never been superseded, and still obtains in the most modern machines. Fig. 2 shows the principle, the carriages being actuated upon the rolling locker method. Though the double tier principle has not been departed from for plain net machinery, the original idea of a single tier machine was never lost sight of, and in 1813 John Lever invented his single tier machine, where there are as many carriages in one row as in two rows in the plain net machine, each carriage being proportionally thinner. Though in the first instance it was intended to make, and did make, plain net, it was soon found that its proper function was the making of fancy laces, nets, edgings, insertions, and millinery laces generally. Fig. 3 shows the essential principle of this machine. The third machine in use, though the same in principle, is really a development comprising some of the features of both the above machines, advantage being taken of those that would best add to its capacity for making lace curtains, where speed and facilities for producing breadth of design are the qualities chiefly required. —W. H.

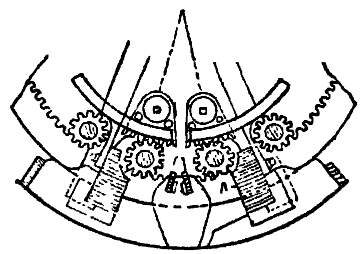

FIG. 2.

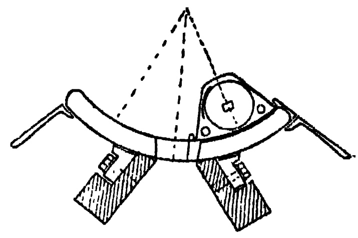

FIG. 3.

Lachrymatory (*Archæol.*) The name given to a small vase or phial, generally elongated in form, found in ancient Roman tombs. The name implies that they were intended for holding tears, but it is more probable that they were intended for other purposes.

Lacing (*Eng.*) The union of the ends of leather belting by means of thongs of leather passed through pierced holes.

Lacing Cord (*Lace Manufac.*) Cotton cord or braid made upon the "dolly" or braiding machine, for lacing Jacquards together.

Lacing Course (*Build.*) A course of bricks bonding the rings or successive courses of an arch.

Lacing In (*Bind.*) Passing the ends of the bands or cords to which the book is sewed through holes made in the boards. When passed through, they are hammered well into the boards, thus attaching the boards to the book. *See* BANDS, BOARDS, *and* KNOCKING-DOWN IRON.

Lac Insect (*Zool.*) *Coccus ficus*, belonging to the same tribe as the Cochineal insect (*q.v.*); perforates the bark of tropical trees, causing an exudation of resin (LAC). As SHELL-LAC the resin is used in making varnishes, sealing wax, and lacquer.

Lacmoid (*Chem.*) Probable constitution,

$$N\begin{cases} C_6H_4(OH)_2 \\ C_6H_3OH:O \end{cases}$$

Reddish brown, shining, amorphous grains; soluble in alcohol, acetic acid, and less soluble in ether and in water; insoluble in chloroform and benzene. To prepare it, resorcin (100 grs.), sodium nitrite (5 grs.), and water (5 c.c.) are gradually heated to 110°; when the reaction is over, the heating is continued at 115° to 120°; ammonia is given off, and the product becomes blue in colour; water is added, then hydrochloric acid till the blue colour is changed to red. The precipitate is filtered off and washed with a little water, and dried at 100°. In dilute solution in alcohol (·2 gr. in 100 c.c.) it forms an important INDICATOR (*q.v.*); acids turn it red, alkali blue. Carbonic acid affects it, also nitrous acid, and sulphuretted hydrogen decolourises it. Salts of the alkaline earths do not affect it. Lacmoid paper can be used to titrate carbonates and sulphides, also chromates (normal chromates turn it blue, free chromic acid red).

Lacquer (*Dec.*) It is by no means easy to distinguish between a lacquer and a varnish; in fact, the distinction is more conventional than real. A lacquer generally means a spirit varnish, and especially those in which shellac is the chief solid

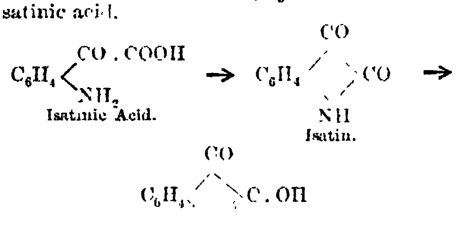
ingredient. The solvent in a "spirit varnish" is not necessarily alcohol, but the varnish must dry by evaporation, and not by oxidation and resinification, as in the case with the fatty varnishes. The solvents used in the manufacture of lacquers are spirits of wine, oil of turpentine, tar oil, petroleum, ether, and benzole, and mixtures of these. Like any other varnish, a lacquer may be coloured, and any resin soluble in a volatile solvent may be employed in its preparation. Those most used are shellac, amber, copal, dammar, sandarach, colophony, asphaltum, indiarubber, and collodion.

Lactalbumin (*Chem.*) A constant constituent of all kinds of milk; but it is always present in small amount. It resembles in general serumalbumin, but differs from this in rotatory power, temperature of coagulation, and in solubility. Said to have been crystallised.

Lactams (*Chem.*) Compounds similar to the Lactones (*q.v.*), but having the ring closed by an Imino group (NH) instead of oxygen; *e.g.*

$CH_2CH_2CH_2CO$ is γ-butyrolactam.
NH

They are formed by heating the γ and δ amino acids, and on boiling with alkalis (*e.g.* NaOH) they are converted to salts of the amino acid from which they are derived (compare Lactones). Certain Lactams exhibit Tautomerism, *e.g.* Isatin—the lactam of isatinic acid.



Tautomeric Form.

The form $C_6H_4\langle {CO \atop N} \rangle C.OH$ is called the Lactim form.

Lacteals (*Zoology*). The lymphatic vessels found in connection with the intestine. They contain a milky fluid (CHYLE), and are concerned in the absorption of fats from the digested food.

Lactic Acid (*Chem.*), $CH_3.CHOH.COOH$. (α-oxypropionic acid). A syrupy liquid, soluble in water, alcohol, and ether. It readily loses water on heating, forming an anhydride,

$$CH_3CHOHCOO.C\left\langle \begin{matrix} CH_3 \\ H \\ COOH \end{matrix} \right.$$

The latter on distillation yields a second anhydride called lactide,

$$CH_3CH\left\langle \begin{matrix} COOC\left\langle {CH_3 \atop H} \right. \\ O\ O\ C \end{matrix} \right.$$

a crystalline solid. Heated with dilute sulphuric acid at 130° it yields aldehyde and formic acid. It behaves at the same time as a secondary alcohol and as an acid, *e.g.* oxidation with potassium permanganate changes it to a ketonic acid—pyruvic acid $CH_3COCOOH$; hydrobromic acid changes it to α-brompropionic acid; hydriodic acid to propionic acid; it forms two kinds of ethyl derivatives, *viz.*

$CH_3CHOC_2H_5COOH$	$CH_3CHOHCOOC_2H_5$
Alcohol Derivative.	Acid Derivative.

It occurs in sour milk, in the gastric juice in dyspepsia, in sauerkraut, etc. It can be prepared synthetically from propionic acid by heating the latter with bromine at 130°, and boiling the product for a long time with much water—

$$\underset{\text{Propionic Acid.}}{CH_3CH_2COOH} \rightarrow \underset{\alpha\text{-Brompropionic Acid.}}{CH_3CHBrCOOH} \rightarrow CH_3CHOH.COOH$$

also from aldehyde by allowing this compound to stand with prussic acid and hydrochloric acid—

$$CH_3.C\left\langle {O \atop H} \right. \qquad CH_3C\left\langle \begin{matrix} OH \\ CN \\ H \end{matrix} \right. \qquad CH_3C\left\langle \begin{matrix} OH \\ COOH \\ H \end{matrix} \right.$$

In quantity it is prepared by inverting cane sugar with tartaric acid, adding sour milk, putrid cheese, and zinc oxide. The process is one of fermentation, and the zinc oxide is added to remove the free lactic acid in the form of the zinc salt, because the ferment ceases action if the acid is allowed to accumulate. The zinc salt is recrystallised, decomposed by sulphuretted hydrogen, filtered, concentrated, and extracted with ether. Lactic acid contains a symmetric carbon

atom, $H - \underset{COOH}{\overset{CH_3}{C}} - OH$, and accordingly exists in three

forms. The synthetic acid, and that obtained by fermentation, are both optically inactive; this form can be resolved by making the strychnine salt and crystallising it, when the lævo-salt separates first. The dextro acid occurs in the juice of muscle and in meat extracts such as Liebig's; it is called SARCOLACTIC ACID.

Lactim (*Chem.*) *See* LACTAMS.

Lactometer. An instrument for determining the specific gravity of milk.

Lactones (*Chem.*) Anhydrides of oxy-acids which have the oxy-group separated from the acid group by two or three carbon atoms. The former are called γ-lactones and the latter δ-lactones; *e.g.* $\underset{\gamma}{CH_2OH}.\underset{\beta}{CH_2}.\underset{\alpha}{CH_2}.COOH$ is called γ-oxybutyric acid, and it readily loses water and forms butyrolactone $CH_2.CH_2.CH_2.CO$, which is a γ-lactone.
O

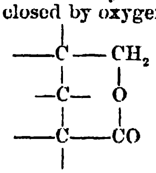
The lactones are liquids or solids, soluble in water, alcohol, ether, which on treatment with alkalis (*e.g.* NaOH) give the sodium salts of the corresponding acid. With halogen acids most of them yield the haloid acid, *e.g.* $CH_2CH_2CH_2CO$ (O) + HBr = $CH_2BrCH_2CH_2COOH$. The lactones are formed from the halogen acids by distillation or boiling with water; from the corresponding ketonic acids by

reduction; from dibasic acids by reduction of the chloride or anhydride. As lactones are only formed by γ- and δ-oxy-acids, it is clear that in the case of a substance of unknown constitution which either behaves like a lactone, or can be converted into a lactone, something can be inferred as to its constitution Thus camphoric acid forms an anhydride which yields a lactone on reduction:

$$C_8H_{14}\left\langle{CO \atop CO}\right\rangle O \rightarrow C_8H_{14}\left\langle{CO \atop CH_2}\right\rangle O$$

Camphoric Acid Anhydride. Lactone (Campholide).

So that in campholide we may infer a ring of four or five carbon atoms closed by oxygen, *e.g.*:



Lactose *or* **Milk Sugar** (*Chem.*), $C_{12}H_{22}O_{11}$. Forms white rhombic crystals containing one molecule water. Soluble in water; insoluble in alcohol. Its solution is dextro-rotatory. Lactose reduces Fehling's solution, also ammoniacal silver; on gentle oxidation it gives a monocarboxylic acid—lactobionic acid; oxidised by nitric acid, it gives a dicarboxylic acid—mucic acid; it yields a characteristic osazone (*see* OSAZONES); boiled with dilute sulphuric acid, it gives dextrose and galactose; it forms an octoacetate. These facts show that it is a hexahydric alcohol and also an aldehyde. It is much less sweet than cane sugar. Lactose occurs in the milk of mammals: human milk contains about 5 per cent. and cow's milk 3·8 per cent. on an average. Lactose is prepared from milk by coagulating the proteid (addition of a little strong acid) and evaporating the whey to a syrup, when crude lactose will crystallise out on standing in a cold place; it is recrystallised. It can be obtained very pure by dissolving in water and precipitating it with absolute alcohol.

Lacunar (*Architect.*) A sunk compartment or panel in a ceiling, etc.

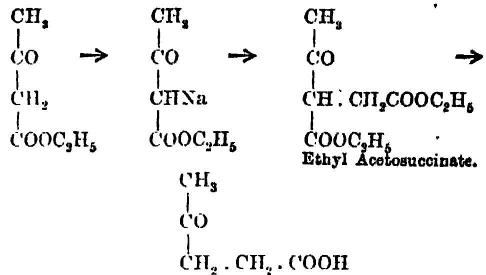
Ladder Rack (*Civil Eng.*) *See* MOUNTAIN RAILWAYS

Ladies (*Build.*) Roofing slates measuring 16 in. by 8 in.

Ladle (*Met.*) An iron vessel, generally lined with fireclay, used for conveying molten metal from the furnace to the moulds. Also an iron spoon used for holding molten lead or other metal, *e.g.* for fixing iron railings, etc.

Lævorotatory Compounds (*Chem.*) Compounds which rotate the plane of polarisation of a plane polarised ray of light to the left. *See* POLARISED LIGHT. If the substance is a solid, it is examined in solution in a suitable inactive solvent. *See* ASYMMETRIC CARBON ATOM.

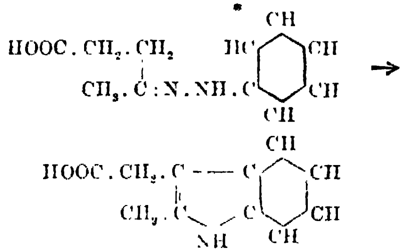
Lævulinic Acid (*Chem.*) β-acetopropionic acid, $\underset{\gamma}{CH_3CO}\,.\,\underset{\beta}{CH_2}\underset{\alpha}{CH_2}\,.\,COOH$. White solid, crystallising in scales; melts at 33°; decomposes on distillation at the ordinary pressure, but distils unchanged at 144° under 12 mm. pressure; very soluble in water, alcohol, and ether. It is obtained by boiling lævulose, or any sugar which yields lævulose on hydrolysis, with dilute sulphuric acid. Synthetically it is prepared from ethyl acetoacetate by acting on the sodium derivative with ethyl monochloracetate, and boiling the product with baryta water:



Ethyl Acetosuccinate.

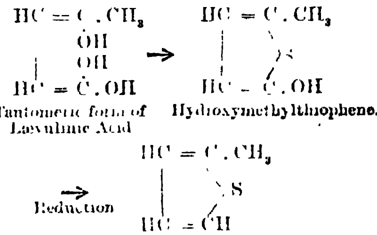
Lævulinic Acid.

As a γ-ketonic acid, lævulinic acid has the reactions of a ketone; thus on reduction it yields (*a*) with sodium amalgam γ-oxyvaleric acid (Na – salt); (*b*) with hydriodic acid it yields normal valeric acid. With hydrocyanic acid, hydroxylamine, and phenylhydrazine it behaves like other ketones; the phenylhydrazine derivative yields an indole derivative when heated with zinc chloride:



a-Methylindole-β-Acetic Acid.

P_2S_5 converts lævulinic acid into methylthiophene:



Tautomeric form of Lævulinic Acid

Hydroxymethylthiophene.

Reduction

Methylthiophene.

Lævulose, Fructose, *or* **Fruit Sugar** (*Chem.*), $CH_2OH\,.\,(CHOH)_3CO\,.\,CH_2OH$. A white crystalline solid (fine silky needles); melts at 95°; readily soluble in water; sweet taste, as sweet as cane sugar. It occurs along with dextrose in all ripe fruits, also in honey. It can be prepared by inverting cane sugar by a dilute acid (*e.g.* sulphuric acid), cooling to 0° and adding slaked lime; on shaking, the sparingly soluble lime-compound of lævulose separates out, leaving the more soluble dextrose compound in solution. After filtering and pressing, the lime compound is decomposed by suspending it in water and passing carbon dioxide through the liquid, when the calcium is separated as carbonate and lævulose remains in solution. On evaporation the lævulose remains as a syrup which crystallises with difficulty. Lævulose is also obtained pure from inulin by hydrolysing the latter with water. It can be obtained from dextrose by converting the latter

into the osazone, hydrolysing the latter with strong hydrochloric acid, and reducing the product:

$$\begin{array}{l} CH_2OH \\ | \\ (CHOH)_4 \\ | \\ CHO \end{array} \rightarrow \begin{array}{l} CH_2OH \\ | \\ (CHOH)_3 \\ | \\ C:N.NH.C_6H_5 \\ | \\ HC:N.NH.C_6H_5 \\ \text{Phenylglucosazone.} \end{array} \xrightarrow{HCl}$$

$$\begin{array}{l} CH_2OH \\ | \\ (CHOH)_3 \\ | \\ CO \\ | \\ CHO \\ \text{Glucosone.} \end{array} \xrightarrow{H} \begin{array}{l} CH_2OH \\ | \\ (CHOH)_3 \\ | \\ CO \\ | \\ CH_2OH \\ \text{Lævulose.} \end{array}$$

Hence lævulose can be synthesised. *See* DEXTROSE *and* OSAZONES. Lævulose is lævorotatory; its dextrorotatory modification is known and the racemic variety is the synthetic sugar α-acrose (*see* DEXTROSE). As an alcohol lævulose forms *esters* with acids or acid anhydrides, etc.; *e.g.* acetic anhydride and sodium acetate yield a penta-acetate, while benzoyl chloride and caustic soda yield a pentabenzoate; with alcohols and gaseous hydrochloric acid it yields ethers; with metallic oxides it yields compounds of the same type as the methoxides and ethoxides; *e.g.*, $C_6H_{12}O_6 3CaO = C_6H_6(CaOH)_3O_6$. As a ketone alcohol it yields on reduction the hexahydric alcohol mannitol, $CH_2OH(CHOH)_4CH_2OH$; on oxidation it yields trioxybutyric and glycollic acids, $CH_2OH.CHOH$ $CHOH.COOH$ and $CH_2OH.COOH$; with hydrogen bromide in presence of ether it yields α-brommethylfurfuraldehyde,

$$\begin{array}{l} CH = CH - CH_2Br \\ | \qquad\quad > O \\ CH = CH \cdot CHO \end{array}$$

With hydrocyanic acid, hydroxylamine, and phenylhydrazine it behaves as a ketone. The compound with hydrocyanic acid,

$$CH_2OH(CHOH)_3.C\begin{array}{l} \diagup OH \\ - CN \\ \diagdown CH_2OH \end{array}$$

on hydrolysis and reduction with hydriodic acid yields methylnormalbutyl acetic acid,

$$\begin{array}{c} C_4H_9 \\ | \\ CH_3 - C - H \\ | \\ COOH \end{array}$$

With excess of phenylhydrazine lævulose yields the same phenylglucosazone as dextrose. Lævulose reduces Fehling's solution and ammoniacal silver, and ferments with yeast like dextrose, but less readily.

Lag (*Weaving*). A strip of wood containing perforations into which pegs are inserted, and which determine the heald shafts to be lifted or lowered.

Lag and Lead (*Elect. Eng.*) If a varying electromotive force act in any circuit, the current produced will not in general be completely in step with the E.M.F. The maximum value of the current may be attained either before or after the maximum value of the E.M.F. Thus in the commonest case of a varying E.M.F., that of an alternating current, a difference of phase is produced between the current and the E.M.F. Let R be the resistance of the circuit, L its self-induction (*q.v.*), K its capacity, and $p = 2\pi n$ where n is the frequency. Then the angle of lag, ϕ, is determined by the equation

$$\tan \phi = \frac{pL - \frac{1}{pK}}{R}$$

If pL be greater than $\frac{1}{pK}$, the difference of phase is positive and the current lags behind the E.M.F., while if $\frac{1}{pK}$ be greater than pL, the difference of phase is negative, or there is a *Lead* in phase. If $pL = \frac{1}{pK}$, there is neither lag nor lead, and the impedance (*q.v.*) is equal to R, and the current in the circuit follows Ohm's Law.

Lagen (*Archæol.*) A liquid measure at one time in use in England, equal to about seven quarts.

Lagging (*Eng.*) (1) The process of covering a boiler, cylinder, etc., with some non-conducting material in order to prevent loss of heat. (2) The material itself which is used in this process. (3) Pieces of wood, etc., used in covering or building up large cylindrical objects, *e.g.* wooden drums, patterns, the centring on which arches are erected, etc.

Lagging Back (*Weaving*). The operation of reversing the pattern chain with the object of removing defective picks, etc.

Lagging of Tides (*Astron.*) At the time of neap tides the interval between the corresponding tides of successive days is greater than the mean, and the tide is said to lag.

Lagos Rubber. *See* CAOUTCHOUC *and* RUBBER.

Lagre (*Glass Manufac.*) A sheet of glass placed upon the flattening stone to prevent scratching in the manufacture of SHEET GLASS. *See* GLASS MANUFACTURE.

Laid Paper. Writing paper showing the wire marks, slightly ribbed. *Cf.* WOVE PAPER.

Lakes (*Dyeing, Dec., etc.*) The word lake has two meanings. For the dyer it means an insoluble colour compound formed on the fibre. It also means (*a*) a pigment consisting of an insoluble white solid or "carrier" dyed by some natural or artificial organic dye; (*b*) a coloured precipitate got by precipitating such dyes with metallic salts. We restrict ourselves to the consideration of lakes in the senses (*a*) and (*b*). The exact nature of the lakes we are concerned with is not accurately known. It no doubt varies, some of them probably being definite chemical compounds, others mixtures. The fact that acid dyes will combine with a metallic oxide as the latter is set free by an alkali (the application of which fact to lake making we shall soon see) would appear to favour the idea that at least the lakes of acid dyes partake of the nature of salts, and may therefore be definite compounds. Lake pigments for artists were formerly made by dyers from waste lac dye liquors (cochineal), and this is the origin of the name. A purple pigment was also prepared, says Pliny, from the scum of the baths in which Tyrian purple was dyed. An enormous number of lakes is now manufactured, and we can only here give some brief account of the principles of their formation, illustrated by a few examples. There are, then, two distinct methods of producing a lake. One is to mix a dye solution with one of a metallic salt, and then to precipitate the metal,

whereupon a precipitation is formed which entangles colouring matter and brings it down from solution in some way not well understood. If the metallic precipitate is white by itself, the colour of the lake may be due to the organic dye only; but the case is clearly different if the metallic compound has an independent colour of its own. The other method is to use a carrier in the solid form, and to throw down the organic dye upon it with a suitable precipitant. The chief CARRIERS used are china-clay, barytes, starch, gypsum, chalk, talc, red lead, and hydrate of alumina. This last method is the one chiefly employed with the basic dyes, and in its application the choice of a carrier is of very great importance, as any given dye has a carrier which will give greater brilliancy of hue and greater covering power than any other insoluble substance. The old madder lakes were excellent examples of the first method. Madder infusion was mixed with alum and precipitated with carbonate of soda. The lake was then filtered off and washed. Brazil wood lake is made in the same way, alum and tinsalt being added to the decoction, and then precipitated with soda. Most modern lakes are, however, made by the second process, or by a combination of the two, in which the carrier is thrown down separately, and then after washing is dyed with a solution of the dye. An ALIZARINE LAKE can be prepared by dissolving 100 lb. of alizarine (10 per cent. paste) in caustic soda, diluting largely, filtering if necessary, and adding a solution of 50 lb. of alum and 3 lb. of chloride of calcium in 80 gallons of water. A coloured lime alumina lake is thrown down. The same lake can be prepared, to give an instance of the combination above alluded to, by precipitating sulphate of alumina to which a little chloride of calcium has immediately before been added, with carbonate of soda. The precipitate of aluminic hydrate and carbonate of lime is then dyed by heating it with alizarine paste mixed with Turkey red oil and a little tannin. WALL PAPER LAKES are prepared from basic dyes by throwing them down upon a carrier of blanc fixe (precipitated barium sulphate), as no other carrier gives a lake with equal body. For BASIC DYES in general, however, the carrier most used is kaolin or porcelain clay. In some cases the carrier becomes dyed sufficiently well by being merely stirred up in the dye solution, but in most cases the action of a separate precipitant of the dye is essential. Alum, either alone or reinforced with carbonate of soda or tannin, is used for the purpose. Many lakes are made with tannin. A solution of alum, or of any suitable metallic salt, is taken, the carrier is stirred up in it with the dye solution, and the whole is then precipitated with a solution of tannin. For basic green dyes quercitron answers better than pure tannin, as it gives a lake of a better colour. The order of the operations may be varied. The carrier may be mixed first with the dye solution and the tannin, adding the metallic solution last. In either case chalk or carbonate of soda is used to complete the precipitation of the metal. These TANNIN LAKES have a bad reputation with oil painters, as they are said to be non-drying, but they answer very well for wall papers and water colour painting. As an instance of the use of a COLOURED CARRIER, the production of violet lakes by precipitating a red dye on to Prussian blue may be mentioned. AZO DYES are precipitated on a carrier with a salt of lead, calcium, or barium. Here the carrier may be used alone with the dye solution, or sodium aluminate or carbonate may be also added before the precipitation. The carrier is usually blanc fixe in paper staining and heavy spar for paint. EOSINE LAKES are much prized for their bright colours, and some of them (vermilionettes) are used as substitutes for vermilion. Lead salts are used as precipitants, and in some cases red lead is used as a carrier. One method of making the lake is to mix a paste of hydrate of alumina with a solution of eosine, and then to add a solution of lead nitrate. Various other eosine lakes of differing shades are made by precipitating the dye on a carrier of porcelain clay or starch, by alum; or by using a carrier compound of a mixture of red lead and gypsum; or by precipitating with salts of magnesium or zinc. Lakes must be well washed after making, till all that can dissolve has been removed. They are sold in powder, in paste, and also in blocks. There seems to be hardly any limit to the possible number of lakes, and their manufacture has become quite a fine art. They are procurable in hundreds of different colours and shades, produced by varying the dye, precipitant, and carrier, as well as the conditions of temperature, degree of concentration of the solution, etc., under which the dye is separated out in the solid form.

Lakes (*Geol.*) Local expanses of inland waters which are usually caused by some special conditions in one part of the channel of a stream, and are essentially quite temporary in character. They are due to various causes, amongst which are (1) the formation of a barrier of some kind, which forces the water back; (2) a local subsidence; (3) mechanical erosion of part of the river bed, such as is caused by glacial action; (4) to the filling, by water, of the craters of recently extinct volcanoes, etc.

Lalande's Cell (*Elect.*) *See* CELLS, PRIMARY.

Lamboys (*Arm.*) A kind of steel skirt reaching from the waist to the knee, and sometimes forming a part of body armour of the Tudor period.

Lambrequin *or* **Mantling** (*Her.*) A small mantle attached to the helmet. It is often arranged so as to form a background for the shield, and the whole forms the achievement. It appears jagged at the edges, as the actual mantle worn by knights in battle became much cut and torn.

Lamb's Tongue (*Joinery*). A flat ogee moulding used on sashes.

Lame (*Silk Manufac.*) *See* HEDDLE.

Lamina, *pl.* **Laminæ.** A thin layer or plate of metal, rock, tissue, bone, etc.

Laminated Work (*Carp. and Join.*) Curved ribs or other structures constructed of thin boards nailed together side by side.

Lamination (*Elect. Eng., etc.*) Building up with flat strips or plates. Cores of transformers (*q.v.*) and many other iron parts of electrical machinery are laminated in order to prevent the production of induced or FOUCAULT CURRENTS (*q.v*) in the metal. The planes of division are arranged to lie parallel to the lines of magnetic force which run through the iron, and at right angles to the direction in which any induced currents would tend to flow. By this means the path of the magnetic lines is unbroken, while that of the Foucault currents is interrupted and the currents are thereby reduced to a minimum.

—— (*Geol.*) An arrangement of the structural planes of a mineral or a rock in such a manner that they form thin parallel plates or laminæ. Thus nearly all coal presents typical examples of lamina-

tion, which is due to repeated alternations of thin sheets of cherry coal, cannel coal, and "mother of coal."

Lampblack. An impure form of carbon obtained by the incomplete combustion of substances such as turpentine, tar, fractions of petroleum not useful for other purposes, all of which are rich in carbon. The process may be imitated by turning up the flame of an ordinary paraffin oil lamp till it "smokes" strongly—that is, till the air supply is insufficient for the complete combustion of the oil. Lampblack consists of about 80 per cent. carbon, the other 20 per cent. being composed of unchanged substance and products of its decomposition by heat, in presence of the limited air supply. Soot is the most familiar form, but its strong brown tinge is fatal to its use as a pigment. The brown coloration is due to other products of partial combustion, and for lampblack manufacture combustibles are chosen which give less of these intermediate products. Oils are generally employed, and the soot obtained is freed from the brown substances by treatment with acids and caustic alkalies, till nothing but deep black pure carbon is left. Lampblack is the pigment of PRINTERS' INK and of CHINESE or INDIAN INK.

Lampoon. A virulent satire, in prose or poetry.

Lancashire Boiler (*Eng.*) *See* BOILERS.

Lance (*Arms*). A weapon consisting of a wooden shaft, shaped at the part where it was held and having a pointed metal head. Used almost universally and in all ages, but especially by knights in the Middle Ages. Also a weapon used in the whale fishery for despatching the whale.

Lance Rest (*Arm.*) In the period when armour was worn the lance rest consisted of a bracket fixed to the right side of the breastplate. The lance now has a strap attached, through which the arm is passed.

Lancet (*Architect.*) The name of one of the periods into which Sharpe divided English Gothic Architecture. His division is based on the form of the window, and Lancet-shaped or acute pointed windows are characteristic of the first part of the Early English period; the dates given by Sharpe being from 1190 to 1245 A.D. *See* CURVILINEAR *and* EARLY ENGLISH.

Lancet Arch (*Build.*) A pointed arch, having the radii of the segments longer than the span.

Lancewood. *See* WOODS.

Land and Sea Breezes (*Meteorol.*) Breezes blowing inland during the day and out to sea at night are commonly found at the sea coast in hot countries; the former is termed a SEA BREEZE, the latter a LAND BREEZE. They are commonly explained by the land being the hotter during the day; cool air rushes from the sea to compensate for the rarefaction thus caused; at night the land cools more quickly than the sea, and an air current in the reverse direction is thus caused. This explanation is, however, incomplete.

Lander (*Mining*). A man who empties a kibble (*q.v.*) as it comes up to the surface.

Landing (*Build.*) A horizontal platform at which a flight of stairs starts or finishes.

Landing Bar (*Lace Manufac.*) A bar peculiar to Lever's machine, to which the catch bars are attached. The two combined hold, support, and at the same time forward the carriages through their required movement.

Landolphia (*Botany*). Climbing plants belonging to the Dicotyledon order *Apocynaceæ*, and natives of Africa. They are the source of part of the rubber ("African rubber") of commerce.

Landscape (*Art.*) A picture representing some view of natural inland scenery.

Landslip (*Geol.*) An accidental displacement of a mass of rock by which it has been transferred from the surface at one part to that of a part near. Landslips are generally due to the undermining action of water in weakening the support which has previously kept an upper bed of rock in its place on a slope. A landslip may occur on a scale of almost any magnitude.

Langsam (*Music*). The German equivalent for Adagio (*q.v.*)

Langued (*Her.*) When the tongue of an animal or bird appears, it is "langued" and the tincture given when differing from that of the beast.

Langue de Bœuf (*Arms*). A weapon of the halberd or partisan character, carried by bodyguards. The broad blade was supposed to resemble the tongue of an ox, hence the name.

Lanoline (*Chem.*) A pale yellow semi-solid; separates into water and an oil on warming. The oil is purified wool fat, and consists of fatty acid esters of cholesterine (*q.v.*) and of an isomeric compound called isocholesterine. It is obtained from sheep's wool by washing the wool, then pressing it while hot, and treating the fat with alkalis to remove acids; alkali is removed by washing with a dilute mineral acid. Used as an ointment.

Lantern. *See* OPTICAL LANTERN.

Lantern Light (*Carp. and Join.*) A glazed light fixed on top of a roof, and having sashes at the sides and ends as well as the top.

Lantern Objective. An achromatic lens or combination of lenses, placed at the proper distance in front of the slide or other object to be exhibited on the screen; it is the part of the optical system which actually produces the image on the screen. The objective of an ordinary lantern is supported by a tube projecting from the front of the lantern, and is provided with a rack and pinion by means of which it may be moved backwards and forwards in order to focus the picture.

Lantern Pinion (*Clocks*). A pinion the leaves of which are cylindrical rods fitted between two circular plates. Advantageously used in the going trains of turret clocks. *See* PINION.

Lanthanum, La (*Chem.*) Atomic weight, 138. A rare metal belonging to the same group of elements as aluminium. Its compounds resemble those of aluminium, and they have similar formulæ; unlike aluminium, it burns in hydrogen at 210°, and on heating it in nitrogen it forms a nitride. It occurs in the rare earths Cerite, Gadolinite, Yttrocerite. Some chemists are of opinion that lanthanum is not a single element. Lanthanum has a complex and characteristic spectrum.

Laocoon (*Sculp.*) The famous group in the Vatican representing the Trojan priest Laocoon and his two sons enveloped by serpents. Regarded as a masterpiece of anatomical knowledge and realistic expression. The group was discovered in Rome about 1506, and is attributed to sculptors of the Rhodian school.

Lap (*Build.*) The distance that roof slates or tiles overlap the next course but one.

—— (*Eng.*) (1) The distance to which plates in a LAP JOINT (*q.v.*) lie over each other. (2) A piece of soft metal or wood, coated with fine emery or some other powder, used in finishing off polished surfaces of hard metal. (3) The form given to a slide valve in order to cut off the steam at a given point. *See* SLIDE VALVE.

—— (*Textile Manufac.*) The fleece of wool as it is delivered from the condenser, or it may be the narrow width of wool from the scribbler or intermediate, conveyed to a subsequent machine by what is known as the Scotch Feed.

Lap Dovetail (*Joinery*). The form of dovetail used in drawer fronts; the joint is invisible from the front, but can be seen on the board forming the side of the drawer.

Lapis Lazuli (*Min.*) Sodium and aluminium orthosilicate and sodium sulphide, $Na_4(NaS_3.Al)Al_2Si_3O_{12}$. Cubic, but rarely in crystals; more often massive. Blue. It is used as an ornamental stone, and also constitutes, when powdered, the pigment ultramarine. From Siberia, China, Hungary, etc. An artificial pigment, of nearly the same composition, has now replaced the mineral as a pigment.

Lapithæ (*Sculp.*) A mythical Thessalian race, represented on the metopes of the Parthenon (Battle of the Lapithæ and Centaurs). *See* ELGIN MARBLES.

Lap Joint (*Eng.*) A joint between two plates, one of which lies over the other for a short distance: the two are fixed together by rivets or bolts.

Laplace's Formula for the Velocity of Sound. *See* VELOCITY OF SOUND.

Laplace's Nebular Hypothesis (*Astron.*) An hypothesis which contends that the solar system has been formed from a vast glowing mass of gas extending beyond the orbit of Neptune, which has gradually contracted, leaving behind rings, which have eventually formed the planets.

Lapped Valve (*Eng.*) A slide valve with lap. *See* SLIDE VALVE.

Lappets (*Cotton Weaving*). A cheap method of ornamenting cloth by means of extra warp or whip yarn. An imitation of embroidery. The mechanism is attached to the loom; there are two forms, *viz.* the SCOTCH or CAM, and the LANCASHIRE or LATTICE.

Lapping (*Linen Manufac.*) When the cloth is bleached and finished, it is cut to lengths and folded up in various ways to suit the market for which it is intended. This is called lapping.

Lap Welding (*Eng.*) Joining two pieces of wrought iron or steel by laying the end of one over the other and welding them together; it is the most usual way of making a welded joint in the forge, and is also employed in making wrought iron tube which is welded at the seam.

Lap Winding (*Elect. Eng.*) One of the methods of winding the armature of a dynamo in which all the windings lie on the outside of the core. The elements or loops are so arranged as to overlap one another. *See* WINDING OF ARMATURES.

Larch (*Botany*). The bark of the larch, *Larix europæa* (order, *Coniferæ*), is used in tanning. *See* WOODS *and also* VENICE TURPENTINE.

Largamente (*Music*). In a broad, dignified manner.

Large (*Music*). *See* NOTES.

Larghetto (*Music*). A diminutive of Largo, somewhat broadly.

Largo (*Music*). Broad, dignified.

Larrying (*Build.*) Bedding the inside bricks of a thick wall in thin mortar.

Larva (*Biol.*) A term applied to the embryo of certain animals, *i.e.* the organism in certain of the early stages of its life, after it is freed from the ovum, but before it attains its adult form, *e.g.* a caterpillar is the LARVA of an insect.

Lash (*Silk Manufac.*) *See* COUPLING.

Latch. A contrivance for fastening a door, etc.; opened either by hand or by means of a key.

—— (*Arms*). Another name for the CROSSBOW (*q.v.*)

Latching (*Surveying*). *See* DIALLING.

Latent Heat (*Phys.*) The quantity of heat necessary to produce a change in the physical state of unit mass of a substance, without producing any change in temperature, *e.g.* 536 calories are necessary to turn 1 gram of boiling water into steam at 100°; therefore 536 is the latent heat for the physical change involved, *i.e.* the vaporisation of water.

Lateral Canal (*Civil Eng.*) A canal running between two points in a river's course, to provide a navigable channel where the part of the river itself is unsuitable, owing to shoals, rapids, etc.; or to cut off a long bend in the river.

Latex (*Botany*). The milky sap of laticiferous tissue occurring in certain natural orders. It is of economic importance, as it contains gum resins, tannins, gums, etc. *See also* RUBBER.

Lath. *See* LATHS.

Lathe (*Eng., etc.*) A lathe is a machine primarily intended for the production of circular objects. The material to be shaped is caused to revolve about a given axis, and a tool is held in a suitable position so as to operate continuously on the work as it revolves. The simplest form is the DEAD CENTRE LATHE, in which the material is supported between two CENTRES or pointed pieces of metal fixed in suitable supports. Rotatory motion is communicated directly to the material by means of a cord or belt. In the primitive POLE LATHE a cord is wrapped round the work; the lower end is attached to a treadle, which is pressed down by the foot, causing the work to revolve in the required direction. The upper end is attached to one end of a long pole, whose other end is fixed, so that the pole bends during the downstroke, and when the pressure of the foot is removed the pole straightens and raises the cord with the attached treadle. As the work necessarily revolves in the reverse direction during this upstroke, the tool is withdrawn until the next downstroke commences. This primitive appliance is still in use in certain industries. The watchmaker's TURN is a small dead centre lathe, accurately constructed of metal, and can be used for very exact and delicate work. In the ordinary form of lathe (fig. 1) the rotatory motion is imparted to the work by a revolving spindle or MANDREL which is supported by a coned bearing at B and an adjusting screw E in a fixed HEADSTOCK H, and driven by a belt passing over a CONED PULLEY C keyed on to

the mandrel. The connection between the work and the mandrel is obtained by some form of CHUCK screwed on at D, which may entirely support the

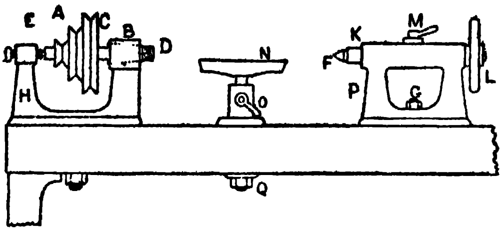


FIG. 1.

material in certain cases, or may support one end, and at the same time impart a rotatory motion to it. In this case the other end of the material is supported by a pointed CENTRE F, carried by the LOOSE HEADSTOCK or POPPET HEAD P. This slides along the bed, but can be fixed in any given position by means of a bolt G, which usually passes vertically downward through the slot between the two cheeks or members of the bed. The centre is then pressed against the work by means of the sliding cylinder K, which supports it; motion is communicated to K by means of a screw, on which is keyed the hand wheel L. When the centre F is screwed up so as to press sufficiently tightly against the work, the sliding cylinder K is clamped in position by means of a screw M. In hand turning the tool is steadied by resting in on a T REST N; this can be fixed at any point along the bed by means of a bolt Q, and can be raised and lowered in its socket, and clamped at any desired height by the set screw shown at O. The bed is usually an iron casting whose cross section is of the form shown in fig. 2. A, A are the two main members, or cheeks, united at the ends and stiffened at intermediate points by webs, one of which is shown at B. The upper surface is made as truly plane as possible, and provided with two V-shaped edges. The poppet and rests fit these V edges, and are kept in place by them. In FOOT LATHES the pulley is driven by a belt running over a heavy flywheel, which is carried on a crank shaft supported on bearings fixed to the standards (or legs), and rotated by means of a treadle; in POWER LATHES a countershaft (*q.v.*) is usually fixed immediately over the lathe, being driven by a belt from the main shafting of the shop. In some modern workshops, however, each lathe is driven by an electric motor, which may be connected directly to the headstock. Lathes intended for heavy metal work are usually provided with BACK GEAR; this is shown in a diagrammatic form in fig. 3. A, A is the mandrel; a pinion B is rigidly fixed to the coned pulley C, and the two can turn together loosely on the mandrel. A shaft D, D, parallel to the mandrel, carries a toothed wheel E and a second pinion F, both being keyed to the

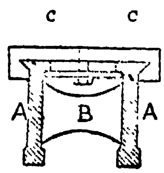

FIG. 2.

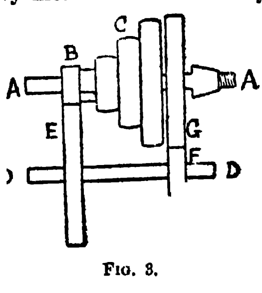

FIG. 3.

shaft, which can be moved parallel to itself so as to bring B and E into gear with each other or draw them apart. When B and E are in gear, the pinion F gears with a second toothed wheel G, which is keyed to the mandrel. Thus the latter revolves at a rate much less than that of the pulley when the gear is in action. When, however, a high speed is required, the shaft D is drawn back by mechanism provided for the purpose, and the toothed wheel G is locked to the pulley C, so that the mandrel then revolves at the same rate as the coned pulley C. Metal turning tools are rarely held in the hand, except in the very lightest work, but are supported in a SLIDE REST, which is attached to the bed of the lathe; by this means the tool is rigidly held, but can be given a linear motion, parallel to the axis of the bed, and a second linear motion at right angles. *See* SLIDE REST. In SCREW CUTTING LATHES the slide rest can be moved along the bed by means of a long square threaded screw parallel to the bed. This screw is caused to rotate by means of a train of wheels connected to the mandrel, so that the slide rest, and therefore the tool, move a given distance during each rotation of the work. This distance depends upon the relative velocities of the mandrel and leading screw, and therefore upon the number of teeth in the gear wheels by which the two are connected. A set of gear wheels, or CHANGE WHEELS, as they are termed, forms part of a screw cutting lathe, and by choosing suitable combinations of these, practically every thread required in ordinary work can be cut. In SELF ACTING LATHES motion can be communicated to the slide rest by means of a shaft, termed a BACK SHAFT, running along the back of the bed; this is so connected as to give either a motion parallel to the axis of the bed for SLIDING (*q.v.*), or a motion at right angles to this direction for SURFACING (*q.v.*) The size of a lathe is usually denoted by the radius of the largest piece of work which it will take in: thus a 5 in. lathe is one in which a cylinder of 5 in. radius (10 in. diameter) can be turned. The length of the bed bears no necessary ratio to this radius; but in many lathes the bed is ten to twelve times the height of the centres, *e.g.* a 5 in. lathe usually has a bed 4 ft. or 5 ft. long. In lathes for special purposes the length of the bed may be different. If a lathe be only intended for turning short objects of large diameter (*e.g.* wheels), the bed may be greatly reduced or be separated altogether from the headstock, and become a mere support for the slide rest, the poppet head being dispensed with altogether. Such a lathe is termed a BREAK LATHE. Very large break lathes are now constructed for turning flywheels, the armatures of large dynamos, and similar objects up to 40 ft. in diameter. A small lathe is often provided with a GAP in the bed (fig. 4). This allows a wheel, etc., of considerably larger diameter than the ordinary work to be accommodated in the lathe. When the gap is not required, it can be filled up by a GAP PIECE or BRIDGE, which is a casting similar in cross section to the bed itself. Lathes for ornamental turning and certain other classes of work are often provided with an OVERHEAD MOTION. This consists of a shaft fixed above the lathe and parallel to the bed, and from it milling cutters or drilling appliances held in the slide rest

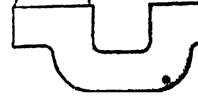

FIG. 4.

can be driven. It is distinct from the countershaft of a power lathe, being frequently driven from the flywheel of the lathe itself, and being further provided with some device for "taking up the slack" or tightening the belt by which the revolving tool is actuated, in order that the latter may be moved along the bed of the lathe while in rotation.

Lathe (*Silk Manufac.*) *See* BATTEN.

Lathe Bed (*Eng.*) The horizontal structure carrying the headstocks, slide rest, etc. It may be a single bar of metal (BAR LATHE) or two parallel bars of hard wood, or a somewhat complicated iron casting with a carefully planed upper surface whose edges are made exactly parallel, in order that the slide rest and back centre may be moved in an accurately straight path.

Lathe Standards (*Eng.*) The legs or frames which support the bed of the lathe.

Laths (*Carp., etc.*) Thin strips of wood, used for various purposes, but especially as a support for plaster; they are fixed so that a space intervenes between each lath and the one alongside. The plaster is forced into these spaces, thus forming a KEY, by means of which it is held in place.

Latitude and Longitude, Celestial (*Astron.*) The angular distance of a star from the ecliptic; it is measured along a great circle which is at right angles to the ecliptic. The angular distance of this great circle from the First Point of Aries is termed the celestial longitude of the star.

—— **Terrestrial.** The latitude of a point is its angular distance from the equator, measured along a meridian (*q.v.*) The longitude of a point on the earth is the angular distance between a meridian through the point and a fixed meridian termed the prime meridian. The meridian passing through Greenwich is the one almost universally used as the prime meridian.

Latitude, Libration in (*Astron.*) *See* LIBRATION.

Latten (*Met.*) A metal resembling brass in appearance, formerly used extensively for making monumental brasses. *See under* BRASSES, MONUMENTAL.

Lattice Girder (*Eng.*) A built up girder, in which the central portion or WEB (*q.v.*) is replaced by a series of diagonal bars forming a crossed or lattice work structure.

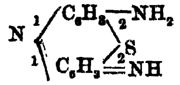
Laudanum (*Chem.*) A solution prepared from opium by treatment with equal parts of 90 per cent. alcohol and water, and then diluted so as to contain threequarters of one per cent. of the alkaloid morphine (*q.v.*)

Laughing Gas (*Chem.*) A common name for nitrous oxide. *See* NITROGEN OXIDES.

Laumontite (*Min.*) Hydrous silicate of aluminium and lime, $Al_2O_3 . 3SiO_2 + CaO . SiO_2 + 4H_2O$. Monosymmetric. It is one of the Zeolites (*q.v.*), and occurs in veins in volcanic rocks as a result of the decomposition of some of their constituent minerals by percolating water. Colour, white to yellow. On exposure it effloresces. Dumbartonshire, Fifeshire, Renfrew, Ireland, etc.

Launder (*Mining*). A trough in which water is led from place to place, for washing ore, working waterwheels, etc.

Lauth's Violet (*Chem.*) Thionine—



Black crystals with green colour when seen by reflected light; soluble in alcohol with violet colour. It is a base, and forms salts with acids, *e.g.* the hydrochloride—a green crystalline solid sparingly soluble in cold water, giving a violet solution. It is obtained by oxidising a solution of paraphenylene diamine with ferric chloride in presence of sulphuretted hydrogen; also by oxidising its leucobase (*see* LEUCO COMPOUNDS) with ferric chloride.

Lava (*Geol.*) The product arising from the cooling of what was originally a fluid mass which has risen, while at a high temperature, to the surface of a volcano and has flowed thence down its slopes. Some lavas cool very quickly, and thus do not flow far from the vent, while others remain fluid much longer, and may flow to distances of as much as fifty miles before coming quite to a standstill.

Lavatories in Workshops (*Hygiene*). Sec. 75, Factory and Workshop Act, 1901, requires that "in every factory or workshop where lead, arsenic, or any other poisonous substance is used, suitable washing conveniences must be provided for the use of the persons employed in any department where such substances are used."

Lavender. The lavender belongs to the natural order *Labiatæ* (*q.v.*) The most important plant is *Lavandula vera*, which is largely cultivated at Mitcham, Canterbury, Ampthill, and Hitchin. The flowers when distilled give true OIL OF LAVENDER, which is extensively used in perfumery and in medicine. It is remarkable that the best oil is procurable from English lavender only, though some maintain the superiority of the French oil; but a comparison between the market prices will at once show the relative estimation in which English and other oils are held. SPIKE LAVENDER is *Lavandula spica*, which yields an essential oil on distillation. The odour of the oil is far less esteemed than that of the oil from *L. vera*, and resembles that of a mixture of the latter oil with rosemary oil. It is used to some extent in soap and other perfumery, but not in medicine. The true lavender oil, which is much dearer, is sometimes adulterated with spike oil.

Law. A LAW in science is a statement of the results which follow from the operation of certain specific natural causes. A law may be deduced accurately from experiment or calculation, or may be inferred from observations of a sequence of events not completely understood.

Law Calf (*Bind.*) The calf skin used for binding law books is generally undyed, *i.e.* white. Law calf is therefore white calf.

Lawn. A light, plain texture linen fabric somewhat like cambric, but more open, and having a more gauzy appearance. It is used for dresses, handkerchiefs, etc.

Law of Constant Heat Summation (*Chem.*) An application of a general law, which holds for all kinds of energy, to the thermal changes occurring during chemical reactions. This law, stated by Hess in 1840, is as follows: Let A be the amount of energy in any units possessed by a system before it undergoes a given change, and B the amount of energy

in terms of the same units, possessed by the system after the change; then (A − B) is the same in whatever way the system passed from its initial to its final state. This law is applied in thermal chemistry to find the heat of formation of substances when it cannot be done directly from the elements themselves—that is to say, in the great majority of cases. Example: Formic acid contains the elements carbon, hydrogen, and oxygen; but it cannot be made by the direct union of the three. To find its heat of formation the procedure is as follows: The formula of the acid is CH_2O_2: so a weight of the acid equal to its formula weight (12 + 2 + 32 = 46 grs.) may be burned in oxygen to carbon dioxide and water and the heat given out during the combustion measured. The result of this process is that 44 grs. of carbon dioxide and 18 grs. of water are obtained, and when these have cooled to a certain temperature the heat given out is 65,900 calories. Now 12 grs. of carbon are burned to carbon dioxide, and the same temperature being reached, this process gives 96,960 calories. Finally 2 grs. of hydrogen are burned to water, and this gives 68,360 calories. The initial system is 12 grs. of carbon, 2 grs. of hydrogen, and 32 grs. of oxygen; the final system is 44 grs. of carbon dioxide and 18 grs. of water. In the first case the final system was reached in two stages, *viz.*: (1) The initial system was converted to formic acid by some process we need not consider and involving an unknown number of calories x. (2) The formic acid was burned to give the final system involving the production of 65,900 calories. In the second case the final system was reached by burning the carbon and hydrogen to give the same final system as before and in this case the number of calories evolved is (96,960 + 68,360). By the law the calories involved in each case is the same. Therefore $x + 65{,}900 = 96{,}960 + 68{,}360 \therefore x = 99{,}420$ calories.

Law of Constant or Definite Proportions (*Chem.*) *See* LAWS OF CHEMICAL COMBINATION.

Law of Multiple Proportion (*Chem.*) *See* LAWS OF CHEMICAL COMBINATION.

Law of Reciprocal Proportion (*Chem.*) *See* LAWS OF CHEMICAL COMBINATION.

Laws of Chemical Combination (*Chem.*) (1) LAW OF DEFINITE OR CONSTANT PROPORTIONS: This law states that in a given compound the elements are united in proportions which are fixed and invariable. The truth of this law has been assailed by more than one famous chemist—for example, by Berthollet (1799) and by Marignac (1860). On account of the doubts raised by Marignac as to the strict validity of the law, Stas undertook two researches—*viz.* (*a*) on the constancy of the composition of so-called stable compounds; and (*b*) on the invariability of the proportions by weight of the elements which go to form a chemical compound. In the first of these he showed that the ratio between ammonium chloride and silver is expressed by a constant whatever may be the method of formation of the ammonium chloride and of the silver chloride; in the second research he showed that in silver chlorate, bromate, and iodate the ratio of silver to oxygen was always constant. (2) LAW OF RECIPROCAL PROPORTIONS: If one substance, A, unite with each of the substances B, C, D, etc., then if B, C, D, etc., unite with each other, they will do so in the same proportions as they united with A, or in some simple multiple or submultiple of these proportions. This law was discovered in 1792. It follows at once from Dalton's Atomic Theory, so that its statement at the present time as a Law of Chemical Combination is mainly of historical interest. (3) LAW OF MULTIPLE PROPORTIONS: When one element unites with another in more than one proportion, these proportions stand in a simple ratio to each other. Dalton discovered this law about 1802, but it was formally announced by his friend Thomson in 1804. The compounds which led Dalton to formulate his important generalisation were few in number. He showed that nitric oxide combines with half its own volume of oxygen, and with double this volume, to form two other compounds; that a given weight of carbon combines with oxygen in two different proportions, one double the other; that carbon combines with hydrogen in two different proportions, one double the other. According to Roscoe and Harden, Dalton had conceived the Atomic Theory first, and deduced this law as a necessary consequence of it. (4) LAW OF GASEOUS COMBINATION (GAY LUSSAC'S LAW): When gases combine together they do so in volumes which stand in a simple ratio to each other and to that of the product of their combination. Example: Chlorine and hydrogen unite to form hydrogen chloride, and we have: vol. of chlorine: vol. of hydrogen: vol. of hydrogen chloride = 1 : 1 : 2. This law was published by Gay Lussac in 1808.

Lay (*Plastering*). *See* PRICKING UP.

—— (*Silk Manufac.*) *See* BATTEN.

—— (*Typog.*) The order in which type is arranged in the cases. The correct placing of the forme on the machine for printing.

Lay Cords (*Bind.*) Pieces of cord forming loops on the cross-bar of the sewing press. In sewing the sections of a book together, one end of each band is attached to a lay cord, which holds it in position. *See* BANDS, KEY (*Bind.*), *and* SEWING PRESS *under* BOOKBINDING.

Layers *or* **Lay Away Pits** (*Leather Manufac.*) The pits in which hides are laid flat in tan liquor with a layer of ground tanning material separating each hide. Sole leather is often laid away in this manner for six to ten months. *See also* LEATHER MANUFACTURE.

Lay Figure (*Art*). A jointed wooden model of the human figure. The joints being articulated, the limbs may be made to assume various positions. Used by artists for arranging draperies, posing, etc.

Laying Down Board (*Foundry*). *See* BOTTOM BOARD.

Laying Out (*Eng.*) The marking of materials, etc., for a piece of work to the full size. The term is applied specially to the marking of sheet metal for boiler making, coppersmiths' work, etc.

Laying Press (*Bind.*) *See* LYING PRESS.

Laying Trowel (*Plast.*) A tool resembling a FLOAT (*q.v.*), having a rectangular steel blade with a handle fixed to the back and parallel to the blade. Used for laying plaster on walls and ceilings.

Lay Light (*Build.*) A horizontal window placed in a ceiling to light a room below.

Lay Marks (*Print.*) The marks or stops used as guides for laying the sheet in printing.

Lay Panel (*Carp. and Join.*) A panel with the grain running horizontally.

Lay Shaft (*Eng.*) The shaft used in gas engines to transmit motion from the main shaft of the engine to the valve gear.

Lea (*Cotton Manufac.*) A seventh part of a hank, *i.e.* 120 yards, sometimes termed a WRAP.

—— (*Linen Manufac.*) The same as "cut." It consists of 120 threads 90 in. long, or 300 yards of yarn.

Leaching *or* **Leeching,** *also called* **Lecking** *and* **Letching** (*Leather Manufac.*) The process of extracting the tannin from barks or other tanning materials. The ground materials are put into large pits or vats called LEACHES, and covered with water. After standing the requisite time the liquor is run off. The process (leeching) is repeated until the tannin is all extracted.

Lead, Pb. (*Chem.*) Atomic weight, 206·9. A silvery white metal, when chemically pure, which quickly tarnishes in the air, owing to slight superficial oxidation. Melts at 327°; specific gravity, 11·3415, or when pressed, 11·347. It is very soft, so that it marks paper, and can be made into wire and piping by pressure. Heated in air it forms the monoxide, then on long-continued careful heating red lead. Quite pure water has no action on lead, but if the water contains dissolved oxygen the sparingly soluble basic lead hydroxide is produced and some hydrogen peroxide is formed: hence a very pure *natural* water cannot be passed through lead pipes if it is to be used for drinking purposes, the lead dissolved being sufficient to cause lead poisoning. This action of water on lead is facilitated by the presence of nitrates, especially ammonium nitrate; but the action is retarded and finally prevented by carbonates, sulphates, and phosphates, the pipe being coated by lead carbonate, etc., which are insoluble in water. Dilute hydrochloric acid only attacks lead in presence of air, and then slightly; but the boiling strong acid forms lead chloride and hydrogen. Hot and concentrated sulphuric acid dissolves lead owing to the formation of a soluble acid sulphate. Concentrated nitric acid does not dissolve lead, probably because of the formation of a minute film of nitrate on the metal, and the nitrate, being insoluble in nitric acid, stops further action; warm dilute nitric acid dissolves lead readily. Lead is precipitated from solutions of its salts, *e.g.* from the acetate, by zinc; in this case the metal is deposited in a treelike form, termed the LEAD TREE. Pure lead can be obtained by distilling ordinary lead in the vacuum produced by a good mercury pump in porcelain tubes, and the process can be watched by the Röntgen rays, which are transmitted by porcelain but not by lead vapour. Lead occurs naturally as sulphide (chief ore), carbonate, sulphate, chromate, and basic chloride; these compounds are called respectively GALENA, CERUSSITE, ANGLESITE, CROCOISITE, MATLOCKITE ($PbOPbCl_2$), and MENDIPITE ($2PbO . PbCl_2$). Also of interest are two naturally occurring compounds of lead chloride, one with lead phosphate, PYROMORPHITE, $PbCl_2 . 3Pb_3(PO_4)_2$; and another with lead arsenate, MIMETITE or MIMETESITE, $PbCl_2 . 3Pb_3(AsO_4)_2$, which are pseudo-isomorphous with Apatite (*q.v.*) Several methods are in use for the extraction of lead from its ores. The following is a brief outline of one of these: The ore is picked by hand, crushed, and washed to remove lighter earthy impurities: it is now spread evenly over the hearth of a reverberatory furnace, in which it is heated to a low temperature while a current of air passes over it. In this operation some lead is obtained and drawn off, but the chief result is oxidation of a part of the sulphide to oxide and sulphate, and escape of sulphur dioxide. The temperature of the furnace is now raised, and some quicklime added to the charge to give it a consistency more favourable to the separation of more lead. This operation is twice repeated, the lime in these stages decomposing any lead silicate which may have formed, and the lead being produced by the mutual action of the lead sulphide, oxide, and sulphate: $PbS + 2PbO = 3Pb + SO_2$

$PbS + PbSO_4 = 2Pb + 2SO_2$

The residue, called slag, still contains lead, and is treated for the recovery of its lead in small blast furnaces in which it is heated to a much higher temperature and with the addition of coke; this lead is not so pure as that from the reverberatory furnace, and has to be refined by melting it at as low a temperature as possible, so that only the lead melts and the impurities float on the top and are removed, while any impurities which dissolve in the lead are removed by oxidation. Galena usually contains silver, and this metal passes into the lead in the process of extraction of lead. Silver was formerly removed by PATTINSON'S PROCESS. In this process lead containing silver is melted and allowed to cool, with stirring, until solidification begins; the *solution* of silver in lead, when it begins to solidify, first separates lead containing little silver, while the lead rich in silver remains liquid. The poor lead is placed in one vessel, the rich lead in another, and the process is repeated on a fresh charge. The process is repeated on the poor lead and on the rich lead until products containing respectively half an ounce to the ton and 500 ounces to the ton are obtained; the former is then sold as lead, the latter treated for its silver by cupellation (*q.v.*) Lead is now desilverised by the PARKES' PROCESS, in which the argentiferous lead is melted and a proportion of zinc, depending on the amount of silver in the lead, is added to it. Silver is far more soluble in zinc than in lead; also when molten, zinc is nearly immiscible with lead, hence Parkes' process may be compared to extracting a substance from water by shaking it with a solvent which is immiscible with water and which dissolves the substance much better than water. When the molten mixture of the three metals has been well agitated by blowing dry steam through it, it is allowed to cool: the zinc floats on top with the silver dissolved in it, and is removed on solidification. The lead retains a little zinc, and has to be refined as described above. The silver is obtained free from zinc by distilling the argentiferous zinc when the latter passes over. Lead is used in making gas and water pipes, in roofing, in the construction of sulphuric acid chambers, in accumulators, in shot making, and it enters into the composition of some important alloys, such as type metal, pewter, solder, and fusible metal. RADIO-ACTIVE LEAD: Lead compounds obtained from pitchblende and other minerals containing uranium and thorium are strongly radio-active. According to Hofmann this activity is due to a primary active component, which is not uranium, thorium, radium, etc. Its activity can be diminished, *e.g.* by adding bismuth nitrate, evaporating with hydrochloric acid, allowing to stand fourteen days, extracting with hot water, filtering, and precipitating the filtrate with sulphuretted hydrogen. The sulphide so obtained shows feeble α-radiation and no β-radiation; but in three to four weeks it regains its original activity. The radio-active lead can be concentrated, and highly concentrated preparations show several peculiarities;

the sulphate becomes red on heating to 400°, the sulphide precipitated from dilute hydrochloric acid solution is grey brown, the chloride becomes rose coloured and the hydroxide yellow. Solutions of radio-active lead salts impart activity to other metals, as gold, silver, platinum. The feebly active lead sulphate from pitchblende (not concentrated radio-active lead sulphate) has its activity increased by exposure to a strong kathode radiation.—W. H. H.

Lead (*Elect. Eng.*) *See* LAG AND LEAD.

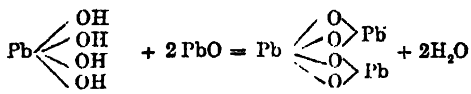
—— (*Min.*) This element is reputed to have occurred native at Alston Moor in Cumberland, at Dufton Mines in Westmorland, near Bristol, in Ireland, in Moravia, and near Lake Superior. In any case, as a mineral it is very rare. The principal ores are galena, cerussite, anglesite, and pyromorphite. There are many rarer ones.

Lead, Action of Water upon (*Hygiene*). The waters which act most rapidly on lead are: the purest and softest, as rain, distilled, and such moorland water as contains a free acid (humic, ulmic, or sulphuric); also those containing organic matter, nitrates, nitrites, chlorides, great excess of carbonic acid or of oxygen. Hard waters containing carbonates, particularly carbonate of lime, have the least effect upon lead. No water should be used for drinking that contains one-tenth of a grain of lead in the gallon; any trace indicates danger.

Lead Burning (*Plumb.*) The formation of a more or less homogeneous joint between two pieces of lead by fusing their edges together with a hot flame. A hydrogen flame, supplied with air (less commonly with oxygen) under pressure, is used. As no solder is used, the joint resembles a WELD (*q.v.*) It is used in ordinary building work and in chemical industries in which corrosive liquids or fumes would rapidly destroy a soldered joint, *e.g.* in the leaden casings of sulphuric acid chambers.

Lead Burning Machine (*Plumb.*) A vessel in the form of a cylinder encased with wood, for generating hydrogen gas used in lead burning (*q.v.*)

Lead Compounds (*Chem.*) Lead forms two series of compounds: in the one series of compounds the metal is divalent, and in the other it is tetravalent. To the divalent series belong all the common lead salts, the oxide from which these salts are derived being the monoxide PbO; to the tetravalent series belong a few unstable salts, the oxide from which these salts are derived being the dioxide PbO_2. *Oxides:* The SUBOXIDE Pb_2O is obtained by careful heating of lead oxalate out of air; it is a grey black powder, easily decomposed into metallic lead and lead monoxide. The MONOXIDE PbO is prepared in large quantities by lead heated in air. When the temperature is insufficient to melt the oxide, the latter is of a dull yellow colour; but when the temperature is high enough to melt the oxide, the latter assumes the crystalline form on cooling, and has a brighter and a redder colour—the former variety is called MASSICOT, and the latter LITHARGE. This oxide may also be obtained by heating the carbonate or nitrate. It is very sparingly soluble in water, has an alkaline reaction, and readily forms salts with acids; it is easily reduced to the metal by heating in hydrogen or carbon monoxide, or on heating in the inner blowpipe flame, or by heating it with carbon. It dissolves in a solution of sugar. This oxide is very important technically: it is used in glazing earthenware; in making drying oils, as it accelerates the absorption of oxygen, on which the "drying" depends; in making flint glass; and in making lead plaster. RED LEAD (triplumbic tetroxide), Pb_3O_4, is obtained by prolonged heating of the monoxide in air at a suitable temperature It is best regarded as lead orthoplumbate—



Orthoplumbic Acid.

It has a bright red colour, becomes black on heating, and decomposes into the monoxide and oxygen. Sulphuric and hydrochloric acids decompose it, yielding the sulphate and chloride and oxygen and chlorine respectively; nitric acid yields lead dioxide and lead nitrate, because lead dioxide is not decomposed by this acid. Red lead is used as a paint and in making flint glass. The DIOXIDE (peroxide, or puce-coloured oxide of lead) PbO_2 is obtained by the electrolysis of soluble lead salts or of lead sulphate suspended in dilute sulphuric acid—

$$PbSO_4 + SO_4'' = Pb(SO_4)_2$$
$$Pb(SO_4)_2 + 2H_2O = 2H_2SO_4 + PbO_2$$

It is also obtained by the action of nitric acid on red lead—

$$\left[\begin{array}{c} Pb_2PbO_4 + 4HNO_3 = H_4PbO_4 + 2Pb(NO_3)_2 \\ H_4PbO_4 = PbO_2 + 2H_2O \end{array}\right]$$

and by the action of oxidising agents on lead monoxide or its salts. Usually it is a dark brown powder, but a naturally occurring variety (Plattnerite) is crystalline, as also is the electrolytic product when slowly deposited. On heating, it gives the monoxide and oxygen. The ease with which it yields oxygen causes it to act as a powerful oxidising agent, *e.g.*

$$5PbO_2 + 2MnSO_4 + 6HNO_3 = 2HMnO_4 + 2PbSO_4 + 3Pb(NO_3)_2 + 2H_2O$$

With sulphur dioxide it combines energetically to form lead sulphate, and with nitrogen peroxide to form lead nitrate. Strong acids (except nitric) give tetravalent lead double salts with the dioxide, while aqueous acids give divalent lead salts, *e.g.*

$$PbO_2 + 6HCl = H_2PbCl_6 + 2H_2O$$
$$PbO_2 + 4HCl = PbCl_2 + Cl_2 + 2H_2O$$

The dioxide has also weak acid properties, forming plumbates with alkaline hydroxides, *e.g.*

$$K_2PbO_3 . 3H_2O$$

Divalent Lead Salts. LEAD CHLORIDE, $PbCl_2$, is a white crystalline solid sparingly soluble in cold water, much more soluble in hot water. It forms a number of basic salts, some of which are used as paints, *e.g.* $PbCl_2 3PbO$ is TURNER'S YELLOW Lead chloride is obtained by adding hydrochloric acid to hot dilute solutions of the nitrate or acetate, or by dissolving lead oxide in hot hydrochloric acid and allowing it to crystallise. LEAD SULPHATE, $PbSO_4$, is a white solid very sparingly soluble in water (1 : 22,800), and less soluble in dilute sulphuric acid (1 : 36,500); readily soluble in caustic soda or ammonium acetate. It is obtained by adding a solution of a sulphate to a solution of lead nitrate or acetate; it can

be crystallised from strong sulphuric acid. LEAD NITRATE, $Pb(NO_3)_2$, is white crystalline solid, readily soluble in water (50 parts in 100 at 12°), and decomposes on heating: $Pb(NO_3)_2 = PbO + 2NO_2 + O$. It is obtained by dissolving lead, lead oxide, or lead carbonate in dilute nitric acid; the salt is insoluble in strong nitric acid. Sometimes used as a weak oxidising agent, as it is slightly hydrolysed by water. LEAD SULPHIDE, PbS, is a black solid insoluble in water. Dilute nitric acid dissolves it on warming, forming the nitrate, and liberating sulphur; stronger acid oxidises it to sulphate. It combines with lead chloride to form a red chlorosulphide, $PbCl_2.3PbS$. *Compare* TURNER'S YELLOW. It may be obtained by heating sulphur and lead together, or by passing sulphuretted hydrogen into a solution of a lead salt. LEAD CARBONATE, $PbCO_3$, a white solid, insoluble in water, obtained by adding ammonium carbonate to a solution of lead acetate. The basic carbonate, $Pb(OH)_2.2PbCO_3$, commonly called WHITE LEAD, is a white solid having a finely granular structure, the grains, which are circular or oval, varying in diameter from ·0001 to ·00004 of an inch. White lead is made (1) by exposing lead moulded in the form of gratings or lattices, termed WICKETS, and supported in vessels containing dilute acetic acid, to the action of fermenting tannery bark; the decomposing bark evolves heat, and gives off carbon dioxide, so that the changes that occur are probably as follows: Lead acetate is formed, then the basic acetate, and finally the basic carbonate (Dutch or Stack method). (2) By acting upon lead oxide in presence of a solution of lead acetate (practically basic lead acetate) with carbon dioxide. White lead is very largely used as a base in making paints, and also as a paint itself. A mixture of white lead with barium sulphate is also used as a paint under various names, as VENICE or HAMBURG WHITE. LEAD CHROMATE, $PbCrO_4$, is a yellow solid obtained by adding a solution of potassium chromate or dichromate to a solution of lead acetate; it is crystalline when the solutions are slowly mixed (by diffusion); amorphous otherwise. It is insoluble in water, but soluble in nitric acid and in caustic soda. Is used as a paint under the name CHROME YELLOW. When treated with caustic soda in the cold, it yields a basic chromate, $PbO.PbCrO_4$, which has a red colour, and is used as a paint under the name CHROME RED. LEAD ACETATE, $Pb(C_2H_3O_2)_2$, also called SUGAR OF LEAD, from its sweet taste, is a white solid crystallising with three molecules of water; very soluble in water, less soluble in alcohol, poisonous. It is prepared by dissolving litharge, PbO, in the theoretical quantity of dilute acetic acid. It is used in medicine, and also largely as a reagent and in the preparation of other lead compounds. On heating its solution with one molecular proportion of litharge, it yields a soluble basic acetate, $PbO.Pb(C_2H_3O_2)_2$, which is used in medicine under the name of Goulard extract. LEAD PLASTER is lead oleate, $Pb(C_{18}H_{33}O_2)_2$, and is made by heating litharge with olive oil and water at 100°. Lead salts of organic acids are easily decomposed by sulphuretted hydrogen into lead sulphide and the free acid; on this account lead salts of organic acids are often prepared as a step in the preparation of the pure acids. For an example *see* FORMIC ACID. *Tetravalent Lead Salts:* LEAD TETRACHLORIDE (Plumbic Chloride), $PbCl_4$, is an unstable yellow liquid, which readily decomposes into the dichloride and chlorine; excess of water converts it into the dioxide

$$Pb\begin{cases}Cl\\Cl\\Cl\\Cl\end{cases} + 4H_2O = Pb\begin{cases}OH\\OH\\OH\\OH\end{cases} + 4HCl$$

$$Pb\begin{cases}OH\\OH\\OH\\OH\end{cases}, \quad Pb\Big\langle\!\!\Big\langle + 2H_2O$$

It is obtained by adding the dioxide to cold concentrated hydrochloric acid, and treating the solution with ammonium chloride, when the yellow ammonium lead chloride $(NH_4)_2PbCl_6$, separates out; and this salt, on treatment with concentrated sulphuric acid, yields the liquid tetrachloride. LEAD DISULPHATE (Plumbic Sulphate), $Pb(SO_4)_2$, is a white powder obtained by electrolysis of strong sulphuric acid in a glass vessel containing a sheet of lead to serve as anode, and a porous pot also, containing strong sulphuric acid and a lead worm to serve as kathode, and to carry a current of water for cooling purposes. The disulphate which is deposited at the anode is collected and exposed on porous plates in a desiccator over strong sulphuric acid. It is not quite pure. Sparingly soluble in concentrated sulphuric acid. Decomposed by water like the tetrachloride. LEAD TETRACETATE, $Pb(C_2H_3O_2)_4$, forms white monoclinic prisms melting at 175°, and soluble in glacial acetic acid and in chloroform containing a little glacial acetic acid. It is immediately decomposed by water into the dioxide and acetic acid; hydrogen chloride gives the tetrachloride and acetic acid. The TETRACETATE is prepared by gradually adding red lead to hot glacial acetic acid to saturation, filtering while hot, allowing to crystallise, then recrystallising from glacial acetic acid. LEAD TETRAMETHYL, $Pb(CH_3)_4$, is a colourless liquid having a slight smell like raspberries; boils at 110°. With iodine it forms lead trimethyl iodide, $Pb(CH_3)_3I$. Lead tetramethyl is obtained by the action of zinc methyl on lead chloride—

$$2\,PbCl_2 + 2Zn(CH_3)_2 = Pb(CH_3)_4 + 2ZnCl_2 + Pb$$

LEAD TRIMETHYL HYDROXIDE, $Pb(CH_3)_3OH$, is obtained as a low melting solid by distilling lead trimethyl iodide with caustic potash; it behaves like a strong alkali. Similar ethyl compounds are known.—W. H. H.

Lead, Desilverisation of (*Chem.*) *See* LEAD.

Leader. A leading article in a newspaper, being an expression of editorial opinion on some subject. Generally set in rather large type.

—— (*Mining*). (1) A small vein which seems to indicate the proximity of larger veins of a metal. (2) A stream which by its colour indicates the presence of minerals.

—— (*Typog.*) A line of dots or dashes cast on one em of a particular body, and intended to guide the eye, thus ....

Leaderette. An editorial paragraph in a newspaper, printed in the same type as a leader (*q.v.*)

Lead Glass *or* **Flint Glass.** *See* GLASS MANUFACTURE.

Leadhillite (*Min.*) A very rare basic sulphate and carbonate of lead. Found at Leadhills in Lanarkshire and in the Caldbeck Fell mines. It occurs in small monosymmetric crystals with a perfect basal cleavage; the lamellæ are flexible. It is of a pearly white colour.

Leading Axle (*Eng.*) The axle carrying the front wheels of a locomotive engine, etc.

Leading Edge (*Eng.*) That edge of the blade of a screw propeller which cuts the water first.

Leading Note (*Music*). The technical name for the seventh degree of the scale, so called from its tendency to lead upward to the tonic, below which it is only a semitone.

Leading Out (*Typog.*) Widening the spaces between lines by means of leads (*q.v.*)

Leading Screw (*Eng.*) A screw with an accurately cut square thread, which moves the slide rest on a SCREW CUTTING LATHE (*q.v.*) *See also* LATHE.

Leading Springs (*Eng.*) The front springs of a locomotive, etc., *i.e.* those immediately over the leading axle. These springs have to sustain a large amount of vibration and shock, and are therefore made of considerable strength, being usually built up of twelve to sixteen curved steel plates.

Lead Joint (*Eng.*) A socket joint in iron piping filled with molten lead, which is driven farther in when it has solidified, in order to fill up any irregularities.

Lead of a Slide Valve (*Eng.*) *See* SLIDE VALVE.

Lead of Brushes (*Elect. Eng.*) The brushes of a dynamo (*q.v.*) do not touch the commutator at the extremities of a diameter which is symmetrical with regard to the pole pieces, but have a forward displacement, termed a LEAD. *See* DYNAMO, figs. 2, 3, and 4. A displacement in the reverse direction is termed a BACKWARD LEAD; it is used in continuous current motors.

Leads (*Typog.*) Strips of lead or other metal of different thicknesses and length, used for effecting spaces between lines of type.

Lead Tack (*Plumb.*) *See* TACKS.

Lead Tree (*Chem.*) *See* LEAD.

Leaf Wood. The term often applied to the timber from the ordinary deciduous trees, *i.e.* those other than the pines and firs.

Leakage, Magnetic (*Elect. Eng.*) The passage of magnetic lines of force through a space or object in which they do not serve a useful purpose; *e.g.* in a dynamo or motor certain lines may pass from one pole piece to another through the air or through the frame or the baseplate, instead of passing through the armature.

Leaning Thread (*Eng.*) A screw thread of which the two sides (seen in cross section) are not inclined at the same angle; an example may often be found on a bolt which has to sustain a thrust in one direction only.

Lean-to Roof (*Build.*) A roof with one slope only, as in a building placed against a high wall. The tops of the rafters are nailed to a plate or bar of wood fixed to the wall.

Leaping Weir (*Civil Eng.*) A weir placed just in front of the intake of an aqueduct, and so constructed that when the stream is in flood, the powerful current will cause the water to shoot right over the opening of the aqueduct, while in normal conditions the water falls gently over the weir and enters the opening. Flood water, which is usually turbid and muddy, is thus prevented, to a very large extent, from entering the aqueduct.

Leap Years (*Astron.*) Years in which an extra day is added to the month of February to bring the calendar into conformity with the time of the earth's revolution round the sun.

Lear (*Glass Manufac.*) An annealing oven. *See* GLASS MANUFACTURE.

Lear Boards (*Carp.*) The boards nailed to the rafters in valleys (*q.v.*) and gutters to dress the lead upon.

Lease, Lese, *or* **Leese** (*Textile Manufac.*) In warping, the crossing of the warp threads alternately at the head end of the warp, and in groups of several threads at the footing end, in order to keep the threads straight when beaming and during weaving.

"Lease" *or* **"Cross" Rods** (*Silk Manufac.*) Two rods placed horizontally through the warp between the harness and the cane roll, the warp threads being alternately above the one rod and under the other, the cross or division thus formed keeping the threads in their proper order, enabling the enterer and twister to play them out in succession and facilitating the tracing and mending of those broken.

Leat (*Mining, etc.*) A watercourse, usually one excavated in the ground, as distinguished from a launder (*q.v.*)

Leather Manufacture. The manufacture of leather may be described as the conversion of raw hide or skin into an imputrescible substance, for certain purposes supple and soft; for other purposes firm and hard. This is effected by three main processes: (1) By impregnation of the hide or skin with a solution of "tannic acid" (tanned leather). (2) By treatment of the hide or skin with mineral salts (tawed or mineral leather). (3) By treatment with oils and fats (chamois or buff leather). In some cases combinations of any two or of all three processes are employed, producing DONGOLA or combination tanned leather. TANNING—SOLE LEATHER: The raw material for this purpose consists of the heavy hides of the ox and cow. These are obtained from practically all over the world, being preserved for transit by sun drying, "curing" with chemical preservatives, or by heavy salting. In process of manufacture they are first soaked in several changes of water to remove the cure, and to bring them back to a soft condition. They are then placed in pits containing a solution of milk of lime, to which is often added caustic soda or alkaline sulphides. The hides are frequently lifted from the pits, and the solutions strengthened. After from six to twelve days, according to thickness, the hides are swollen and the hair is loosened; they are then drawn on to a sloping beam, and the hair pushed off with a blunt knife. After the hair has been thoroughly removed, they are rinsed in water to remove excess of lime, again drawn on to the beam, flesh side upwards, and the fat and flesh left by the butcher is shaved off by means of a sharp fleshing knife. After again soaking, they are "rounded" by cutting off the belly and shoulder portions; the remaining portion, the "butt," is generally about 5 ft. square. Previous to entering the tan liquors, this raw butt is placed in water containing a weak acid to remove the lime, after which it is suspended in weak tan liquor and moved forward into successive pits containing tan liquor of greater strength. When evenly coloured, the butts are no longer suspended in the liquors, but are laid flat in them and "handled" frequently from pit to pit. When about half tanned the butts (goods) are put into still stronger liquors, and between each butt a layer of tanning material is sprinkled. This process is known as "laying away," the goods being laid in these liquors for periods varying from fourteen

days to three months. When thoroughly tanned, the whole period occupied varying from two to twelve months, according to thickness of the hide and the material used, the leather is removed from the pits, allowed to drip, and slowly dried until semi-dry, at which stage the leather is scoured and cleaned by hand or machine. This scouring removes dirt and all particles of tanning material, and flattens out the surface of the leather, making it smooth. A light coating of oil is applied; it is further dried and rolled under a heavy roller to give it firmness and solidity. After still further drying, a second rolling may be given when necessary, and the leather is then hung up in a heated shed until quite dry, when it is polished with a flannel cloth or brush. This completes the process. TANNING MATERIALS: Up to about fifty years ago practically the only tanning material used was oak bark, but gradually other tanning materials of greater strength have been introduced. Among the most important are valonia (the acorn cup of the Turkish oak), myrobalans (the fruit of an Indian tree), mimosa or wattle bark (from Australia and Natal), algarobilla and divi-divi (the fruit of two Indian trees), sumach (the leaf of a shrub growing chiefly in Sicily), and, more recently, mangrove bark. A still more important development in leather manufacture has been the introduction of strong tanning extracts of chestnut, oak, quebracho, and hemlock. Oak extract is chiefly manufactured in Hungary from oakwood. The wood is cut into fine shreds and soaked in hot water, and the liquor, after decolorisation, is concentrated in vacuum pans to a required density, and sold in casks. Chestnut extract is manufactured by similar means in France and Corsica, quebracho extract in the Argentine, and hemlock extract in Canada and the United States. The introduction of these materials has enabled the tanner to considerably shorten the process of leather manufacture. Previous to their introduction, when oak bark was the only tanning material obtainable, the manufacture of sole leather required from one to two years, as oak bark contains but little tannic acid or "tannin," this being the active principle of a tanning material. With the introduction of the newer materials, however, which contain from three to seven times as much tannin as oak bark, much stronger solutions or liquors can be used, with the result that the process may be completed in from three to nine months. LEACHING: Previous to making liquors from the tanning materials, these are ground or crushed in the mills, and then placed in large vats or pits and "leached" by maceration with water. The "leaches" are generally arranged side by side and material put into each, water being then run into one leach, and, after standing a few hours, being drawn off into the next leach by means of a pump. The liquor, on passing through each successive pit, gains in strength, until liquors are obtained containing as much as 10 per cent. of tannic acid. Into these liquors, strengthened with extract, are placed leathers of which the tanning is almost finished, and, as the strength is absorbed by the leather passing through, the liquors gradually work down through the tanyard until, on reaching the suspenders or early stage of tanning, the strength of a liquor is exhausted, and it is discarded as useless. SOLE LEATHER, as the term implies, is used for the soles of boots, shoes, and slippers. The thicker portion, cut from the butt or back, is used for heavy boots; that cut from the shoulder is somewhat thinner, and is used for light summer shoes and boots; and that cut from the belly is used for slippers and sandals. Hide shoulders and bellies undergo a like process of tanning to that described; but being thinner than butts, the tanning is completed more quickly. UPPER AND DRESSING LEATHERS: The hides and skins used for these leathers are the lighter and thinner ones. These undergo practically the same preparatory process of soaking, liming, unhairing, and fleshing as the heavy hides. But a softer and more supple leather is required, and this is obtained by tanning the goods in weak liquors, handling them frequently, and using tanning materials which are in their nature soft and not strongly astringent. When the process of tanning, similar to that already described, is completed, the leather, after dripping, is partially dried, lightly oiled, and, without scouring, cleansing, or rolling, is dried out. It is then ready for the process of "CURRYING AND DRESSING." This process may be generally described as impregnating the leather with oils and greases, and usually is as follows: The leather from the tanner is first softened by steeping in warm water; it is then worked over on both sides with brushes and stone knives to remove soluble tannins, dirt, and particles of tanning material, and afterwards bleached by steeping in warm liquors containing sumach or other suitable bleaching agent. After dripping, the leather is hung up to bring it into a suitable condition for stretching, which is done by laying it on a slate or stone table, and drawing it out from centre to edges by means of a brass or stone knife. The leather is now oiled on the upper or grain surface, and a coating of oil and tallow (dubbin) is brushed well in on the under or flesh side; it is then hung in a cool shed, when the moisture in the leather gradually dries out, its place being taken by the oil and tallow. This process may be repeated according to the amount of grease which it is desirable to incorporate into the leather, this depending upon the purpose for which the leather is to be used. If for BELTING, the leather is heavily stuffed with grease; for light STRAPS and HARNESS, less is applied; if it is for the UPPERS OF BOOTS and SHOES, only a light coating is necessary. The leather, having received the requisite stuffing, is slightly oiled, hung in a room for three or four days, and then laid in pile for the grease in it to set. Excess of grease is now removed from the surface by means of a blunt "slicking" or smoothing tool, and the leather is again stretched and polished; it is then ready for cutting into belting or straps. When the leather is required to be finished black for harness or for bootwork, it is blackened either by means of a solution of logwood and iron or by brushing with an aniline dye. Some leathers are finished flesh side outwards, in which case they are "waxed" with successive coatings of a mixture of lampblack and oil, the leather being dried between each coat, and finally polished by rubbing over with a rounded glass tool. FANCY LEATHERS: These leathers are manufactured from the skins of sheep, goats, calves, and seals. The skins arrive in this country in a similar condition to the hides of oxen and cows, already referred to. CALF LEATHER: The skins, after the preliminary process of soaking, liming, unhairing, and fleshing, are "puered" by steeping in a fermenting solution of excrement, and afterwards cleansed by drenching in a solution of fermenting bran. This dissolves out some of the interfibular substance and softens the skin. The tanning is carried out in a series of vats or pits, commencing with weak liquors and finishing with strong, the skins being handled frequently from one pit to another. The liquors are made chiefly

from oak bark. The leather when tanned is scoured and cleansed similarly to sole leather, but is usually shaved on the flesh side to make the whole skin of one thickness. Previous to drying it is oiled, and when dry it is sponged over with a solution of soap and mucilage; it is then redried and polished by brushing. If for shoework, the leather, after tanning and scouring, is dyed the requisite shade by immersion in a solution of aniline dye-stuff, rinsed to remove excess of dye, lightly dressed with oil and tallow, dried (excess of grease being removed as with curried leather), and polished by brushing; it is then ready for the shoe factory. MOROCCOS: The preliminary preparation of goat skins for tanning is in general the same as that of calf. This being completed, the goods are tanned in solutions of sumach; this tanning material imparts to the leather a light cream colour. Sumach being a rapidly penetrating material, the tannage requires from two to six days only. When tanned, the skins are "struck out" to remove excess of tan liquor, nailed on frames, and dried; when dry, the skins are soaked back, scoured, shaved to even thickness, and dyed in paddles or trays with a solution of aniline dye. When the requisite shade has been obtained, the skins are struck out to remove excess of dye, dried, damped slightly, and grained by hand to bring up the natural grain of the skin. A seasoning solution, consisting of blood, milk, or a suitable mucilage, is then rubbed on the surface, and the skins are glazed by machine, and sometimes re-grained and re-glazed: they are afterwards sorted into sizes in the warehouse. This leather is used for upholstery, bookbinding, pocket books, and other fancy work. SHEEP: The wool is the most valuable part of a sheep's clothing, being usually worth from four to six times as much as the skin. To remove the wool the flesh sides of the skins are painted with a strong paste of lime or sodium sulphide, and the skins then laid flesh to flesh; in about twenty-four hours the fleece can be removed by hand. After the wool is removed the pelts are treated similarly to goat and calf, tanned in bark or sumach liquors, dyed and finished in a similar manner to moroccos to make ROANS or BASILS, which are used for the cheaper class of slipper work, upholstery, and linings for boots. Many sheep skins are split, after liming, by passing the skin between two rollers which press it against a revolving knife. This splits the skin evenly, producing a thin grain split and a heavier flesh split. The grain split is tanned out in sumach, and is known as a SKIVER. After dyeing and finishing it is used for bookbinding and other fancy work, the flesh split being used for manufacturing CHAMOIS LEATHER. SEAL SKIN: These skins being full of grease or oil are, after soaking, blubbered. This consists of rotating the skins in tepid water in a large revolving drum to liquefy the fat, and working the skins over several times on a sloping beam with a blunt knife. By this means the grease is pressed out of the skin, after which it is limed and tanned in a similar manner to morocco and calf. Seal leather is used for portmanteaux, dressing cases, purses, and other fancy work. OIL AND BUFF LEATHERS: This heading includes chamois leather, buck-skin, suède glove leather, and leather for military accoutrements. Chamois leather is made from the flesh split of the sheep skin (*see under* SHEEP *above*); suède glove leather from the flesh split of goat, lamb, and deer skin; buff leather from heavy hides from which the grain surface has been removed by the buffing knife. For oil dressing the skins must be heavily charged with lime. After sprinkling with cod oil, they are placed in machines known as stocking mills, in which they are constantly beaten and turned, and as the oil is absorbed fresh oil is sprinkled on the skin. During the process the skins heat, owing to the decomposition of the oil, and care must be taken that they do not overheat and burn. After the requisite amount of oil has been beaten into the skins they are laid in piles to heat and for the oil to oxidise; when they have finished heating, the excess of oil is pressed out, the leather is then washed in an alkaline solution to remove all trace of oily matter, washed in water, bleached until the colour changes from brown to light yellow, softened by staking, and trimmed; the surface is then smoothed by pressing with a revolving emery wheel, which completes the process. TAWED LEATHERS: The term is applied to leather dressed for gloves; the skins used consist of lamb, kid, and deer. The preliminary processes of soaking, liming, puering, and drenching having been carried out, the skins are then placed in large revolving drums and rotated together with a tawing paste made of alum, salt, flour, and yolk of egg mixed into a thin paste. This paste penetrates the skin, and on completion the skins have been transformed into a white, tough leather. They are then dried and allowed to lie in stock for some weeks, to age. This ageing process makes the skins softer and tougher. They are then slightly damped with clean water, and are stretched over a staking knife. This staking process is repeated until the skins are sufficiently soft, after which they may receive a second drumming in a tawing paste in order to still more toughen the leather, the drying and staking being again repeated. They are fluffed on a fine emery wheel on the flesh side until of even thickness throughout; they are then dyed on the grain surface by brushing the skins over with a solution of any suitable dye-stuff, the alum acting as a mordant and fixing the dye. When dry they are sponged over with a mixture of white of egg, milk, and water, and ironed with a fairly hot iron to glaze. This makes the skin ready for the glover. CHROME LEATHER: The practical manufacture of chrome tanned leather dates from 1881, but mineral salts, chiefly those of iron and aluminium, had been used for a considerable time in the manufacture of leather. Modern chrome leather, both light leather for the uppers of boots and heavy leather for harness and belting work, is made by impregnating the skin (after the preliminary liming, unhairing, and fleshing have been completed) with a solution of chrome salt. The skins are generally placed in a pit or drum containing a solution of bichromate of potash, to which is added sufficient hydrochloric acid to set free the chromic acid. The chromic acid is at once absorbed by the skin, giving it a deep yellow colour; the skins are then removed from this solution and are placed in a second solution containing sulphurous acid or a sulphurous acid salt. This second bath reduces the chromic acid to chromic oxide and other complicated chrome salts. The leather, on emerging from this bath, is of a greeny white shade. After washing free from acid, the skins are shaved to even substance and placed in a revolving drum and drummed in a weak emulsion of soap and oil. After this fat-liquoring, the leather may be dyed with any aniline dyes, and after striking out, slowly dried. Before the leather is quite dry it is stretched and softened by staking, after which it is glazed, dried, and finished. Heavy hides for belting and harness work are usually tanned by a one-bath process. This consists of a solution of a basic chrome salt; the hides, like in ordinary tanning,

commence in a weak liquor and gradually, day by day, move into stronger liquors. By this process the heaviest hides may be tanned in from six to eight days. The process is frequently accelerated by tanning in a revolving drum, or by any suitable means of keeping the hides or liquor in constant movement. Chrome leather has made enormous strides since its introduction, and practically 50 per cent. of the uppers of boots are now being made of chrome leather. It has completely replaced the French calf and calf kid.—J. G. P.

Leathers (*Eng.*) CUP LEATHERS, etc. (*q.v.*), used in the packing of hydraulic presses. *See* HYDRAULIC PRESS.

Lebes (*Archæol.*) A large vessel, generally of metal, used by the Greeks and Romans for culinary and other purposes, *e.g.* for catching the water which was poured over the hands and feet after meals.

Lebhaft (*Music*). The German equivalent for VIVACE (*q.v.*)

Leblanc Process (*Chem.*) *See* ALKALI.

Lecithins (*Chem.*) Compounds of glycerine with fatty acids, phosphoric acid, and choline, *e.g.*

$$\begin{array}{l} CH_2OOC.C_{17}H_{35} \\ | \\ CHOOC.C_{15}H_{31} \\ | \\ CH_2O.PO.\left\langle \begin{array}{l} OH \\ OCH_2CH_2.N(CH_3)_3OH \end{array}\right. \end{array}$$

is a lecithin containing stearic and palmitic acids. They are wavy crystaliine solids, soluble in ether or ether chloroform. They are hydrolysed by dilute sulphuric acid or by baryta water to choline, fatty acid, and glycerine phosphoric acid. They form double salts with platinic chloride and cadmium chloride, and the latter has been shown to be dextrorotatory. The lecithins occur in brain and nerve tissue, in the blood, very largely in yolk of egg, and in growing vegetable cells. The lecithin from yolk of egg can be obtained by extraction with ether alcohol, distillation of extract, treatment of residue with alcohol, filtration, addition of alcoholic H_2PtCl_6, when the platinum double salt is obtained as a precipitate. The double salt is treated with sulphuretted hydrogen to remove platinum, filtered, and evaporated. Lecithin from yolk of egg is now used in medicine: it increases the number of red and white corpuscles, and is used in tuberculosis.

Leclanché Cell (*Elect.*) *See* CELLS, PRIMARY.

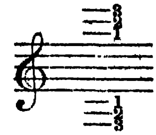
Lectern. A reading desk, especially that from which the lessons are read in a church.

Lecythus (*Pot.*) An ancient Greek vase with a narrow or constricted neck.

Ledged and Braced Door. The same as a LEDGED DOOR, with the addition of braces or pieces of wood running diagonally across between the opposite ends of two successive ledges.

Ledged Door (*Carp and Join.*) A door constructed of parallel boards or battens, placed vertically, and held together by horizontal rails or LEDGES, to which they are nailed.

Ledger Lines (*Music*). Short lines drawn above and below the stave for those notes which exceed the compass of the stave. Ledger lines are always counted outwards from the stave, *e.g.*



The first ledger line below the treble stave is the same note, C, as the first ledger line above the bass stave.

Ledgers (*Build.*) The horizontal poles of a scaffold on which the PUTLOGS (*q.v.*) rest.

Leeching (*Leather Manufac.*) *See* LEACHING.

Left Hand Thread (*Eng.*) A screw thread which runs round the screw in the opposite direction to the usual one; if the screw be viewed in vertical elevation, the thread appears to run upward as it is followed from right to left.

Legatissimo (*Music*). Very smoothly: as connected as possible.

Legato (*Music*). Smoothly, connected; abbreviation *leg.*, shown in music by a curved line over or under the notes:  or 

Legend (*Coins*). The letters or words appearing on a coin or medal.

Legend Line (*Typog.*) The line or lines placed under an illustration in a book or periodical to signify to the reader the nature of the illustration.

Leggiero (*Music*). Lightly; abbreviation, *legg.*

Legume (*Botany*). A dehiscent fruit setting free its seeds by the separation of two valves (*e.g.* Pea, Bean). The characteristic fruit of the order *Leguminosæ.*

Legumin *or* **Vegetable Casein.** A proteid very much resembling casein in milk. It is present chiefly in the seeds of beans and peas, and exists largely in combination with sulphur and phosphorus.

Leguminosæ. One of the most important and widespread of Dicotyledon orders. The peas, beans, clover, vetches, lentils, ground nuts, and many others form valuable food and fodder plants, while tropical forms yield timber, fibres, dyes, gums, resins, and oils.

Leicester Reds. *See* BRICKS.

Leish (*Silk Manufac.*) *See* COUPLING.

Leit Motif (*Music*). A musical theme to illustrate certain characters or ideas in a story. It recurs on each occasion these characters or ideas are brought forward. Especial use was made of the Leit motif by Wagner in his operas.

Lemon. *See* CITRUS.

Lemon Chrome (*Dec.*) A pale yellow pigment consisting of lead chromate, mixed with lead sulphate.

Lemon Grass Oil. An oil used in medicine and in perfumery; is distilled from the entire grass, *Andropogon citratus* (order, *Gramineæ*).

Lemon Juice (*Hygiene*). Valuable on account of its anti-scorbutic power; its use has practically eradicated scurvy from our navy and mercantile marine. The Merchant Shipping Act, 1867, requires that after ten days at sea each person shall receive an ounce of lemon or lime juice daily. Both lemon and lime juice contain citric acid (the principal constituent), some malic acid, proteid, and sugar.

Lenard Rays (*Elect.*) *See* RADIATION.

Leno (*Cotton Manufac.*) A combination weave for light fabrics (*e.g.* veils, curtains), consisting of a plain and figure weave and some form of gauze structure.

Leno Brocade (*Cotton Manufac.*) A brocade figure on a gauze ground.

Lens (*Light*). A single lens is a portion of a refracting medium, bounded by two co-axial spherical surfaces of equal or different radii. One of these surfaces may be plane, *i.e.* its radius is infinite. *See* CONCAVE, CONVEX, MENISCUS LENS, *etc.* The term LENS is also applied to a combination of lenses suitably mounted for purposes of photography, etc. As the rays most active in forming the photographic image are situate at the violet end of the spectrum, while those which affect the eye most strongly correspond to the yellow and yellowish green, it is necessary, in order to obtain a properly focussed image, that the lens be corrected for chromatic aberration, the violet and yellow rays being brought to a focus at the same point.

——, **Achromatic.** A combination of two (or more) single lenses, usually in contact, which produces deviation without dispersion (*q.v.*) It is more correctly termed an ACHROMATIC COMBINATION, and in the commonest cases (*e.g.* the object glass of a telescope or a so-called single photographic lens) consists of a convergent or convex lens of crown glass, cemented by means of Canada Balsam to a divergent or concave lens of flint glass.

Lenticular (*Min.*, *Mining*, *etc.*) Lens-shaped; applied to flat masses of ore, etc.; thinning out at the edges.

Lentil (*Botany*). *Lens esculenta* (order, *Leguminosæ*). A food plant from Western Asia, cultivated from ancient times for the sake of its nutritious seeds.

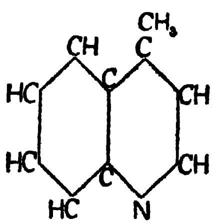
Lento (*Music*). Slow. The movement is slower than that indicated by ADAGIO.

Lenz's Law (*Elect.*) When currents are induced in any conductor by the motion of the conductor or a neighbouring magnet, or by another conductor in which a current is flowing, the direction of the induced current is such as to tend to stop the motion by which it is produced.

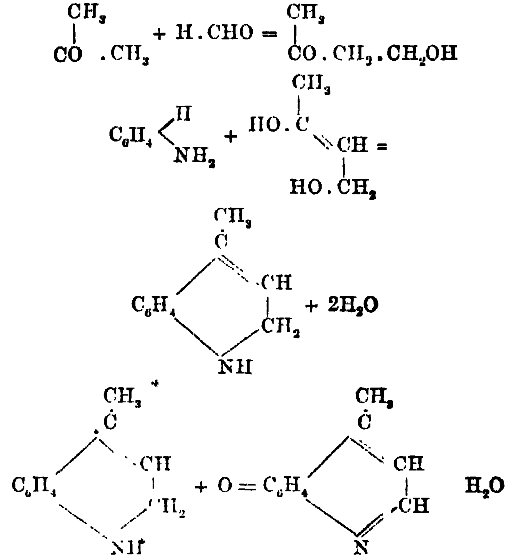
Leonids (*Astron.*) The swarm of meteorites which pursue their path round the sun in a period of about thirty-three years, but which every year, about November 15, meets the earth in her orbit, and gives us the phenomenon of a shooting star display. The main part of this swarm meets the earth every thirty-three years. The main showers occurred in 1833, 1866-7, and a not very brilliant shower in 1901.

Leopard, Lupard, *or* **Lybbardes** (*Her.*) Anciently "a lion passant guardant" was blazoned "leopard." The lions on the shield of England are thus blazoned, and are not, as some have supposed, leopards. When a leopard's head appears without any part of the neck, it is blazoned a "leopard's face."

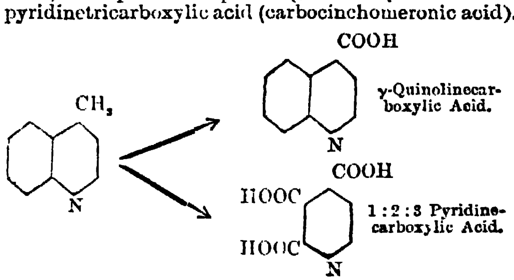
Lepidine (*Chem.*) (γ-Methylquinoline)



A colourless liquid; boils at 257°; smells like quinoline; soluble in alcohol and benzene. It occurs in coal tar; has been synthesised by condensing acetone with formaldehyde (in the form of methylal) by hydrogen chloride, adding aniline, and heating with concentrated sulphuric acid.



It is formed (amongst other products) by distilling cinchonine (*q.v.*) with caustic potash. On oxidation with chromic acid it yields γ-quinolinecarboxylic acid; with potassium permanganate it yields 1:2:3 pyridinetricarboxylic acid (carbocinchomeronic acid).



Lepidolite (*Min.*) A basic fluosilicate of potassium, lithium, and aluminium. Monosymmetric. It is one of the MICA group (*q.v.*) From Cornwall, Kinrossshire, Ireland, Moravia, Saxony, etc.

Lese (*Textile Manufac.*) *See* LEASE.

Letching (*Leather Manufac.*) *See* LEACHING.

Letterpress. Printing impressed by type, as distinguished from printing done from plates or lithographs.

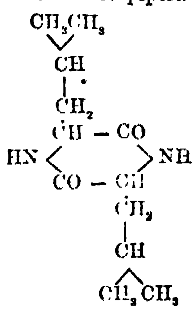
Letting Down (*Eng.*) Softening hardened steel by heating it up to a definite temperature. *See* TEMPERING.

Leucine (*Chem.*) $\begin{matrix}CH_3\\CH_3\end{matrix}\!>CH.CH_2OHNH_2.COOH.$ White shining crystalline leaves with fatty feel; soluble in 48 parts of water at 12°, and in 800 parts of alcohol. Rapidly heated, it yields isoamylamine; but on carefully heating it can be sublimed unchanged. Nitrous acid replaces the amino group by OH. Ferric chloride gives a red colour with a solution of leucine.

It forms a characteristic copper salt. The leucine obtained from albuminoids by the action of acids is optically active; that obtained by the action of baryta water is inactive. Leucine is found in many parts of the body, and it is a constant decomposition product of albuminoids, *e.g.* on digestion, putrefaction, treatment with acids or alkalis. The best source is the cervical ligament of the ox. It is obtained from this as follows: The ligament is boiled with acetic acid and water till free from connective tissue; then with 1 part of sulphuric acid containing 3 parts of water for three hours; poured into sufficient milk of lime to neutralise the sulphuric acid; diluted with water, filtered, and washed. The filtrate is now boiled with milk of lime, again filtered, and neutralised. On concentration the leucine crystallises out. It is purified by boiling with animal charcoal and re-crystallising. Leucine has been synthesised from isobutyricaldehyde and hippuric acid, which yield α-benzoylamino-β-isopropylacrylic acid anhydride:

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>CH.CHO + H_2C.N:C.OH.C_6H_5$$
$$\qquad\qquad COOH$$
$$\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>CH:CH.\underset{|}{C}.N:\underset{|}{C}.C_6H_5 + 2H_2O.$$
$$\qquad CO - O$$

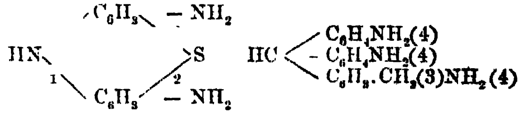
The acid corresponding to the above anhydride, on heating with excess of concentrated ammonia, yields benzoic acid, isovaleric acid, and leucine. Leucine contains an asymmetric carbon atom, so that it can exist in the dextrorotatory, the lævorotatory, and the racemic forms. Naturally occurring leucine is lævorotatory; the synthetic leucine is racemic. To split the racemic form it is converted into the benzoyl derivative by the Baumann-Schotten reaction (*q.v.*) This derivative, being much more strongly acid than leucine itself, can be united to an optically active alkaloid, such as strychnine or brucine, and the dextro and lævo salts separated by crystallisation. They yield the corresponding leucines on decomposition with an alkali. Leucine ethyl ester is prepared by passing hydrogen chloride into leucine in alcohol, decomposing the hydrochloride by an alkali, adding potassium carbonate, and extracting with ether. As this compound distils unchanged, it can be used to purify leucine. On being heated, the ester forms a piperazine derivative called leucinimide, which is 3 : 6—di-isobutyl—2 : 5—diketopiperazine:



a white crystalline solid, soluble in alcohol and melting at 276°.

Leucite (*Min.*) An aluminium potassium silicate, $K_2O.Al_2O_3.4SiO_2$. Alumina = 23·5, silica = 55, potash = 21·5. Cubic at 500° C., though at lower temperatures it shows double refraction and other anomalous properties. White to yellow grey. It is an important constituent of many of the more recent lavas, especially those of basic or sub-basic composition. It is allied in composition to some of the felspars, and is therefore often referred to as a felspathoid. It is of very rare occurrence in any lavas of earlier date than the later Tertiary period.

Leuco Compounds (*Chem.*) Colourless or only faintly coloured substances, which on oxidation yield dyes, and only differ from their oxidation products by containing two or more hydrogen atoms in the molecule than the dye, *e.g.*



Diamidothiodiphenylamine. Leuco Compound of Lauth's Violet (*q.v.*)

Para (3)-triamidodiphenylmetatolylmethane Leucaniline. The Leuco Compound of Rosaniline (*q.v.*)

Leucomaines (*Chem.*) A name given to an ill defined class of substances obtained from meat extracts. They are crystalline solids which produce vomiting, diarrhœa, and stupor. The commonest member of the class is called xanthocreatinine, and it has the formula $C_5H_{10}N_4O$—yellow leaves, bitter taste, basic in character; shows the amphoteric reaction (that is, turns blue litmus red; and red litmus blue). The constitution of the leucomaines is unknown.

Level (*Build, etc.*) *See* SPIRIT LEVEL.

—— (*Civil Eng.*) An open channel along which water flows, *e.g.* the Bedford level.

—— (*Mining*). An excavation, usually horizontal, along the course of a vein of ore.

—— (*Surveying*). An instrument for determining the relative heights of two points. Usually consists of a telescope capable of accurate horizontal adjustment which is used in conjunction with a graduated staff. The latter is held vertically on each of a series of stations, and observed through the telescope. The image of certain points in the graduation of the staff will coincide with the horizontal crosswire in the eyepiece, and the distance between these various points will be the difference of level of the stations.

Levelling (*Eng., Surveying, etc.*) (1) Making a surface horizontal. (2) Making a surface plane or flat. The latter is not a strictly correct use of the term, but it is commonly employed. (3) In surveying, the determination of the relative height of various stations.

Level Surface. A level surface may be defined as one parallel to the surface of a fluid at rest, *i.e.* one which is everywhere at right angles to the direction along which gravity acts.

Lever (*Mechanics*). A rigid bar turning about a fixed point termed the FULCRUM. A force is applied (usually transversely) at one point, and by means of the rigidity of the material is used to overcome a second force or resistance applied at a second point. The first force is usually termed the POWER, the second the WEIGHT; both terms are objectionable.

Lever Box (*Eng.*) The frame or box in which is fixed the axis of the levers used in controlling the motion of a crane.

Lever Escapement (*Watches*). A detached escapement in which the pallets, instead of being on the balance staff, are mounted on a separate arbor carrying a lever, by the fork of which impulse is communicated to the balance, and unlocking performed. *See also* RUBY PIN, ESCAPEMENT.

Lever Jack (*Eng.*) A small lifting jack, consisting of a support carrying the fulcrum of a simple lever, the short arm being applied to the weight to be raised, and the longer arm being moved by hand.

—— *or* **Locker Jack** (*Lace Manufac.*) An interceptor, used in lace curtain manufacture, that is brought into and out of action by the positive movement of a Locker bar.

Lever Safety Valve (*Eng.*) The form of safety valve (*q.v.*) used on most stationary boilers, in which the valve is kept down by a loaded lever, hinged at one end to the casting which carries the valve seat.

Lever's Machine (*Lace Manufac.*) One of the principal machines employed in the making of twist lace; invented by John Lever in 1813.

Lewis *or* **Lewisson** (*Build.*) A device attached to a hoisting chain for lifting blocks of stone.

Leyden Jar (*Elect.*) One of the earliest forms of electrical CONDENSER. It consists of a wide mouthed glass bottle or jar, the inside and outside of which are covered with tinfoil up to a certain distance from the top: these coatings form the two plates of the condenser, and can be charged up to a high difference of potential by an electrical machine; when discharged by momentarily connecting the coatings, a powerful spark may be obtained. To facilitate charging and discharging, the inner coat is connected to a metal rod projecting from the mouth or opening of the jar, and terminated by a metal sphere. The inner coating is now often formed by a metal lining, or even by a suitable quantity of some conducting liquid, such as sulphuric acid.

Li (*Chem.*) The symbol for LITHIUM (*q.v.*)

Lias (*Geol.*) The lowest subdivision of the Jurassic System. In Western Europe these rocks are chiefly of marine origin, and consist of alternate beds of clay and more or less argillaceous limestone, with some subordinate sandstones. Several well defined zones, each characterised by the occurrence within it of some particular species of Ammonite, form a remarkable feature of these rocks.

Libenthenite (*Min.*) A basic phosphate of copper, $4CaO \cdot P_2O_5 \cdot H_2O$. Orthorhombic; in dark green crystals and massive. Cornwall, Hungary, the Urals, etc.

Libration (*Astron.*) Variations in the inclination of the moon's axis which cause its poles alternately to incline towards and recede from the earth are called Librations in Latitude. Librations in Longitude are displacements at right angles to the above, due to variations in the moon's angular velocity round the Earth.

Lich Gate *or* **Lych Gate** (*Architect.*) A gate at the entrance to a churchyard under the roof of which the first portion of the Burial Service can be read.

Licker In (*Cotton Manufac.*) A saw toothed covered cylinder at one end of a carding engine, about 9 in. in diameter, which takes the cotton from the scutcher lap as it is fed, and transmits it to the wire filleted large cylinder for carding; sometimes termed "TAKER IN."

Liebermann's Reaction (*Chem.*) There are two totally distinct reactions known by this name: (*a*) In ordinary chemistry it refers to the Nitroso Reaction. When a nitrosamine (*see* NITROSO COMPOUNDS) or a nitrite is added to phenol in concentrated sulphuric acid, the liquid diluted, and an alkali added, a beautiful blue to violet coloration results. (*b*) In Physiological Chemistry it refers to a colour reaction for albumins. When a pure albumin is boiled with concentrated hydrochloric acid, a deep blue coloration is produced. The blue colours are not related chemically in the two reactions; in the latter it is probably chlormethylfurfuraldehyde which is the cause of the colour.

Lieblich Gedact (*Music*). Small scale gedact (*q.v.*)

Lierne Rib (*Architect.*) A rib used in Decorated Gothic architecture as an ornamental feature in the rib and panel vaults. It lies in the vaulting surface between the ridge ribs and the ribs springing from the imposts, and divides the vaulting surface into panels. *See* RIB AND PANEL VAULT.

Lierne Vaulting (*Architect.*) Vaulting containing Lierne Ribs (*q.v.*)

Lievrite (*Min.*) An iron calcium silicate, $H_2O \cdot CaO \cdot 4FeO \cdot Fe_2O_3 \cdot 4SiO_2$. Orthorhombic; also massive; black. From Elba, the Harz, Saxony, Norway, the United States, etc.

Life (*Eng.*) The period during which an object may be kept in actual use, or, in the case of objects only used intermittently, the number of separate times it may be used.

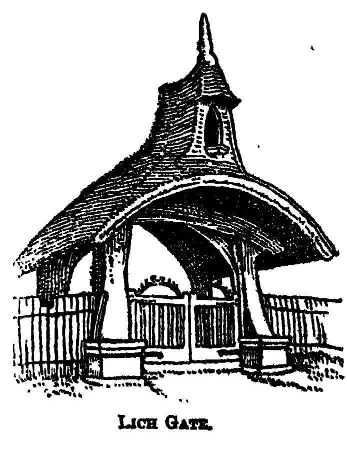
Lifebuoy Signal. *See* HOLMES' SIGNAL.

Lift. An appliance for raising weights through a vertical distance, *e.g.* from floor to floor in a building; it may be actuated by hand or by machinery of some description, acting by means of ropes or cables, or may be directly connected to the ram of a hydraulic press having a cylinder of length sufficient to raise the weight the required distance.

—— (*Foundry*). The upper portion of a mould, which is raised to enable the pattern to be withdrawn after it has been moulded.

Lift Bridges (*Civil Eng.*) A bridge with a roadway which can be raised bodily from its supports. It is a somewhat unusual type; the largest is in Chicago, where a roadway of 50 ft. width is carried over a span of 130 ft., and can be raised to a height of 155 ft. by steel cables running in vertical steel towers at each end of the bridge.

Lifter (*Foundry*). A moulder's tool used for extracting loose



LICH GATE.

sand from a mould; the term is applied also to iron hooks fixed so as to support the sand in the upper or LIFT portion of the mould.

Lifting (*Foundry*). (1) The process of removing the upper part of the mould or of withdrawing the pattern itself. (2) The bursting of the top of a mould through the pressure of the fluid metal.

Lifting Blocks. PULLEY BLOCKS (*q.v.*)

Lifting Plate (*Foundry*). Iron plates let into and fastened to a pattern; they have tapped holes into which iron rods or handles termed LIFTING RODS or SCREWS can be fixed to aid the withdrawal of the pattern.

Lifting Screws (*Foundry*). *See* LIFTING PLATE.

Lifting Shutters (*Carp. and Join.*) Window shutters hung on cords like sashes.

Lifting Straps *or* **Irons** (*Foundry*). Strips of thin iron attached to a pattern to serve as handles in withdrawing it from the sand.

Lift Pump. The ordinary suction pump for raising water a distance not exceeding 30 to 32 ft.; as a rule, 25 ft. is regarded as the limit. The lift pump in its simplest form consists of a cylinder fitted to a tube placed in a reservoir of water. A valve opening upwards covers the opening of the tube at its junction with the cylinder. In the cylinder is placed a piston worked by means of a lever—the pump handle. The piston is also fitted with a valve opening upwards. When the piston is raised its valve, owing to atmospheric pressure, remains closed, the lower valve opens, and air (or water) is sucked into the cylinder. When the piston descends, its valve opens, and the lower valve closes. As the atmospheric pressure on the surface of the water in the reservoir is constant, it drives up the water into the tube; each stroke causes a further rise in the water level, until ultimately it reaches the spout and escapes. *See also* PUMPS.

Lift Valve (*Eng.*) A disc or cup just fitting the valve opening or seat; it rises vertically, and so forms a passage round its edge. The valves of gas engines, most pumps, etc., are usually lift valves.

Ligature (*Typog.*) Type consisting of two or more letters joined together and cast on one body, *e.g.* ff, fi, ffi, fl, ffl.

Light. That portion of the radiant energy transmitted by wave motion through the ether (*q.v.*) which produces the sensation of sight when it falls on the retina of the eye, or which is capable of producing an image by its action on a photographic plate. *See also* INTENSITY, INTERFERENCE, POLARISATION, REFLECTION, REFRACTION OF LIGHT.

—— (*Build.*) (1) A general name for any kind of window. (2) The name given to each perpendicular space or division of a window that is separated by mullions.

Light Carburetted Hydrogen (*Chem.*) *See* METHANE.

Lighthouse (*Civil Eng.*) The term lighthouse is usually applied to a lofty permanent structure erected on a rocky or solid foundation in the vicinity of some dangerous point of the sea coast. It is provided with a powerful light at the top, and the necessary accommodation for a staff of men, and frequently with bells, syrens, and other signalling apparatus.

Lightning (*Meteorol.*) When the air between two clouds charged with electricity, or between a charged cloud and the earth, is subject to an electrical strain, and the strain cannot be resisted, a disruptive electrical discharge occurs, and lightning is the result.

Lightning Arrester (*Elect. Eng.*) A device for protecting electrical apparatus from the effects of lightning. In most forms a conductor connected to earth is placed in close proximity to conductors which are included in the circuit; the atmospheric discharge occurs across the air gap so formed, rather than along the main wires of the circuit. In many cases this discharge would start a dangerous arc across the gap; hence most arresters have some automatic device for extinguishing it. The earthed conductor sometimes possesses a series of projecting points, forming a COMB ARRESTER.

Lightning Conductor (*Meteorol.*) A broad ribbon of copper running from the earth to a point or set of points projecting above the summit of a building. The base should be connected to a large mass of metal or some other conducting substance buried in the earth.

Light Petroleum (*Chem.*) LIGROIN (*q.v.*)

Light Railway (*Civil Eng.*) Local or branch lines constructed in a cheaper manner than ordinary railways, and often running along or beside an ordinary road.

Light Ratio (*Astron.*) The absolute scale adopted for star magnitudes (*q.v.*)

Light Running (*Eng.*) (1) Machinery is said to be "light running" when the friction at the bearings is reduced to a minimum. (2) The term is also applied to machinery when the load or work done is much below its usual value.

Lights (*Painting, etc.*) Those parts of a picture where the light appears to be most brilliant; any illuminated surface or object as represented in a picture. *See also* CHIAROSCURO.

Lightship (*Civil Eng.*) A strongly built vessel anchored near shoals or rocks, and carrying a powerful light, thus serving as a lighthouse. It is constructed so as to roll as little as possible in rough weather, in order that the light may be steady.

Light Year (*Astron.*) The unit of distance adopted in stating the distances of stars, since the diameter of the earth's orbit is too small to serve as a unit. The length of this unit is about sixty-three thousand times the distance of the earth from the sun.

Lignin *or* **Lignine** (*Botany*). The constituent of the cell walls of the elements of wood and bast fibres. It is probably a mixture of several compounds.

Lignite (*Geol.*) A variety of coal in which the vegetable tissues have lost only a small part of their component oxygen and hydrogen, the process of conversion being incomplete. *See under* COAL.

Lignum Vitæ. *See* WOODS.

Ligroin (*Chem.*) The fraction of American petroleum which comes over on distillation between about 90° and 120°. It consists chiefly of paraffin hydrocarbons containing from 6 to 8 carbon atoms; and it is used chiefly as a solvent for organic substances.

Liliaceæ (*Botany*). One of the largest Monocotyledon orders, cosmopolitan in distribution, and varied in habit. It includes the Onion, Shallot, Garlic, and Asparagus among food plants; others yield fibres, resins, and drugs, while the purely ornamental members of the order are very numerous.

Limb (*Astron.*) The edge of the disc of the moon, sun, or a planet.

Limbus (*Archæol.*) The rim of a crater or wine-cup.

Lime (*Botany*). A variety of the citron (*Citrus medica*; var. *acida*; order, *Rutaceæ*), producing the well known fruit and beverage. *See* CITRUS *and also* WOODS.

—— (*Chem.*) A popular name for calcium oxide. *See* CALCIUM COMPOUNDS. It is also used in combination, as in the popular names CHLORIDE OF LIME (bleaching powder, *q.v.*), MILK OF LIME (calcium hydroxide in water), QUICK LIME (calcium oxide), SLAKED LIME (calcium hydroxide), and SUPERPHOSPHATE OF LIME (a mixture of calcium acid phosphate and calcium sulphate).

Lime Blast (*Leather Manufac.*) A stain on leather due to the lime on the skin or hide having become carbonated, owing to exposure to the air or to washing in hard water. Forms dark cloudy stains on finished leather.

Lime Blue (*Dec.*) This is an almost obsolete pigment. Its colour is due not to lime, but to copper. The lime is really a filling. The manufacture consists essentially in precipitating sulphate of copper solution with ammonia, adding more ammonia so as to redissolve the blue precipitate of cupric hydrate, and then gently heating with milk of lime. A precipitate consisting of a mixture of calcium sulphate and hydrated copper oxide is gradually formed; this is filtered off, washed, and dried at a low temperature. The ammonia may be generated by the lime, and to do this sal-ammoniac is first added to the sulphate of copper. More milk of lime is then required, as calcium chloride is formed as well as sulphate, and takes no part in the formation of the pigment, being washed away in the filtration. Care must be taken that only very moderate heat is used in making lime blue; high temperatures blacken it. Lime blue has the faults of all copper pigments—*viz.* being poisonous and turning black on exposure to the air of towns. Ultramarine is often passed off as lime blue.

Lime Light. *See* OXYHYDROGEN FLAME.

Limestones (*Geol.*) Rocks, usually of organico-chemical origin, which consist essentially of carbonate of lime in a solid state, formed chiefly in the sea, but in some cases also in fresh water. Their origin is due in large measure to the vital action of animals or of plants, which convert solutions of other lime compounds, especially the sulphate, into the carbonate, this being eventually left in the solid form. The waste products also of these organisms, living or dead, set up chemical reactions upon the lime salts in solution around them, and thus cause precipitates of carbonate of lime, which are added to the organically formed constituents, and serve to form the compound under consideration.

Lime Water (*Chem.*) *See* CALCIUM COMPOUNDS.

Liming (*Leather Manufac.*) To remove the hair from skins and hides, they are soaked from one to three weeks in a mixture of lime and water. This liming swells the skins, and enables the hair to be removed by hand or machine. *See also* LEATHER MANUFACTURE.

Limit of Elasticity. *See* ELASTIC LIMIT.

Limma (*Sound*). The ratio of two notes of frequency, 16 and 15, *i.e.* the interval $\frac{16}{15}$.

Limoges Enamels. *See under* ENAMELS.

Limonene (*Chem.*) *See* TERPENES.

Limonite (*Min.*) A hydrate of iron, $2Fe_2O_3 . 3H_2O$. It occurs in mammillated forms having a radiating structure, or more often in crusts and amorphous masses. Light yellow to black. Streak always brownish yellow. As clay ironstone it is much used as an ore. Of very wide distribution.

Linalool (*Chem.*) (Dimethyl—2 : 6—octadien—2 : 7—ol—6) $(CH_3)_2\ C : CH . CH_2 . CH_2 . COHCH_3 . CH : CH_2$. For the name see NOMENCLATURE. A colourless liquid smelling of May blossom; boils at 194°—198°; it contains one asymmetric carbon atom, and its dextro, lævo, and inactive forms are all known. Dilute sulphuric acid converts it into terpinhydrate, while glacial acetic acid and sulphuric acid convert it into terpineol. On oxidation it yields methyl-heptenone and then lævulinic acid (*q.v.*) Linalool occurs in many sweet smelling oils, *e.g.* free in oil of lavender, oil of linaloes (from white cedar of Cayenne), coriander oil, etc.; and as acetate in oil of lavender, oil of bergamotte, etc. It is best obtained by fractional distillation of oil of linaloes. Used in perfumery. *See also* TERPENES.

Linarite (*Min.*) Basic lead and copper sulphate, $PbO . CuO . SO_3 . H_2O$. Monosymmetric. It occurs in crystals of a characteristic blue colour, as the result of the decomposition of other lead ores. A rare mineral. From Cumberland, Leadhills, Spain, etc.

Linch Pin. A pin put through a transverse hole in the axle of a vehicle to prevent the wheel coming off.

Line. (1) A mathematical conception, having length and direction, but no breadth or thickness. (2) A nautical term for the EQUATOR (*q.v.*) (3) A unit of measurement equal to $\frac{1}{12}$ of an inch; now rarely used.

—— (*Art*). Contour, outline, method of rendering form. In pl. the word signifies DESIGN; the distinctive features in a design or in the composition of a picture, apart from the colouring.

—— (*Linen Manufac.*) The best portion of the flax after it is hackled or combed. Sometimes the points and root ends are cut off, leaving only the centre portion, which is the most valuable. It is then called "CUT LINE."

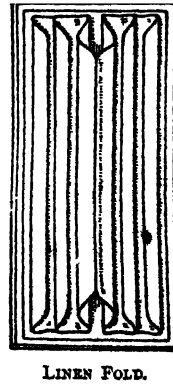
Linea Elastica (*Phys.*) *See* ELASTICA.

Line and Pins (*Build.*) A long line attached to iron pins. Used for keeping the courses in a brick wall straight.

Linear Velocity. The velocity or speed with which a body moves along a path whether straight or curved, as distinguished from ANGULAR VELOCITY (*q.v.*)

Line Engraving. *See under* ENGRAVING.

Linen Fold (*Architect.*) An ornament used on panels, and resembling the folds of linen. It was introduced late in the Perpendicular style. *See* DORSE.



LINEN FOLD.

Linen Manufacture. Linen is made from the fibrous inner bark of the *Linum usitatissimum*, whence it takes its name. The common name of the plant is "Flax," from the Dutch

Vlasch or German *Flachs.* It is probably the oldest textile fabric in existence, and was much esteemed by the ancient Egyptians, who were skilled in its manufacture thousands of years before the Christian era. Drawings representing the various processes of manufacture are to be found depicted on their tombs, and it was regarded as an emblem of purity because it was not eaten by moths, did not rend easily, neither was it furnished by any animal subject unto death, as silk and wool were. The plant has a wide range, and may be found in the burning plains of Egypt as well as in the frigid Russian climate; but a temperate climate is most suited to the growth of a good fibre. The plant is now largely cultivated, both for its fibre and seed, in Holland, Belgium, France, and Ireland, also in Russia, where large quantities of a coarser description are grown. The best flax comes from Courtrai, where the water of the River Lys is particularly suited to retting it. A moist temperate climate favours its growth, and when properly grown it is a very pretty crop, with its long slender stalks about $2\frac{1}{2}$ or 3 ft. long, terminating with bunches of delicate blue flowers. When it is considered ripe enough, it has to be carefully pulled and tied up in bunches. It is then "rippled" to clear the seed off, and may be either dried and stacked, as on the Continent, or at once steeped, as is done in this country. The steeping or "retting" of the flax consists of placing it in large dams of stagnant water, where the gummy matters binding the fibres together and to the stem of the plant ferment, and are dissolved away. This allows the fibrous portion to be easily stripped from the stem. The time required to effect this varies considerably with the temperature, but about ten or twelve days will usually be sufficient. As soon as fermentation ceases, the retting process should be carefully watched, as it is very important, in order to avoid waste in the subsequent processes, that the flax should be just sufficiently retted and not overdone. When sufficiently steeped, it is taken out of the steep hole and allowed to drain, and afterwards spread on grass fields to dry and get the sun and atmosphere, which completes the steeping process, and enables the fibres to be more readily separated. This process is called "grassing" or "crofting," and usually occupies from six to ten days according to the weather, fine weather with occasional showers being the best. When sufficiently grassed and dry, it is gathered up and bound into sheaves. It may then be stacked or taken to the scutch mill for "scutching." Scutching consists of beating out the bone or stem of the plant and leaving the fibres. This is usually done by holding the flax in handfuls over upright pieces of flat iron, close to which strong wooden blades fastened on a shaft are rapidly revolved. The handfuls of flax are turned till they are quite clean, with only the fibre remaining. Many methods have been tried with the view of superseding retting and scutching, which are very primitive processes, but they have not been very successful. When scutched, the flax is sent to the markets, where it is purchased for the spinning mills. The flax has now to be manufactured into yarn and cloth, and the first process is to comb the flax in order to free it from all short and twisted fibres and separate all bunches of fibres that may be sticking together. The combs consist of a number of pins fixed in a block of wood, and the flax is drawn in handfuls over these till it is quite straight and clean. The combs vary in fineness; the first, called a rougher's tool, is strong, with the pins set wide apart, and the work is called "roughing." The finer hackling used also to be done by hand, but is now done by machinery. The bunches of flax, suspended by one end, are combed by steel combs fastened on an endless chain beginning with medium coarse combs, and passing on over finer ones till it is finished. When one end of the flax is combed, it is turned, and the other end combed likewise. Sometimes this completes the hackling, but more frequently it undergoes a still finer process of hand hackling over very fine combs. This is called sorting, as the men who comb the flax separate it into parcels of different degrees of fineness. Sometimes the flax is used the full length of the fibre, sometimes it is cut across. When dressed, the flax is called "line," and if cut it is called "cut line." The combings from the line and the ends cut off it all go as tow, and are carded and spun for tow yarns. The line is now ready to be prepared for spinning. SPINNING MILLS are usually divided into "dressing," "preparing," "spinning," and "reeling" departments. The preparing includes the various processes necessary to make the flax into a "rove" ready for spinning. The first thing to be arranged is the mixture of flax to be used to make a yarn of the quality required. It is then taken to the spread boards, where it is spread out in small parcels overlapping each other and drawn forward on revolving bands to a set of rollers, which press the parcels of flax together, and form them into a flat tape sufficiently firm to hold together. At the same time that the flax is being drawn forwards a number of small combs called "gills" are made to rise up through it, and on the other side of these a second set of rollers, revolving more quickly than the first ones, draw out the band of flax through the gills and make it a finer and more uniform tape than it otherwise would be. This tape of flax is called a "sliver." The sliver is now very much thicker than would be required for spinning into yarn, and also if spun in this way would make a very irregular thread, the thicks and thins being caused by overlapping the small parcels of flax when spreading them out, and by reason of these parcels not being exactly alike in thickness. A thread made by twisting this first sliver would be very irregular in thickness, and to overcome this difficulty several slivers are next run together (called doubling), and are then drawn out greatly in length, the operation being repeated until the resulting sliver is pretty well equalised in thickness. At the last drawing and doubling it gets a slight twist, and is wound on large bobbins in a frame called a "roving frame." This completes the "preparing" process, and the rove is ready to be spun. FLAX YARN is spun on two systems, which are much alike in principle, though they vary considerably in detail. In both, the spinning is done on the throstle or fly frame, the principal difference being that in one case the rove is spun dry, whereas in the other it passes through water of varying degrees of heat before it reaches the drawing rollers, according to the quality of yarn to be spun. It then passes on to the spindles and flyers, where it gets the requisite amount of twist, and is wound on a bobbin. The process is the same when the rove is spun dry, but when spun wet the fibres of flax are more easily drawn on each other, and the machinery must be arranged to suit the requirements of both cases. When the bobbins are full, they are cleared off and empty ones put on the spindles by little girls called "doffers." When wet spun, sometimes the

yarn is dried on the bobbins and used in this state for making cloth, but more frequently the bobbins are sent to the reeling rooms to be reeled into hanks. The reels are large cylindrical frames, 90 in. in circumference, and 6 or 8 ft. long, fixed to revolve in a horizontal position, and a number of threads from bobbins set on pins at certain distances apart are attached to these, and the turning of the reels winds the yarn on them from the bobbins. Every 120 revolutions winds 300 yards of yarn from each bobbin round the reels, and this is one "cut," and is separated or marked from the next one by twisting a piece of twine round it. When twelve of these cuts are wound on the reels, they are full, as twelve cuts make one hank, and this is the way the yarn is put up. The hanks are now taken off the reels and sent to the drying loft, where they are dried on poles. After this they are made up into bunches of 3, 6, 9, or 12 bundles, each bundle containing 60,000 yards of yarn, or 16 hanks and 8 cuts; sometimes, however, there are only 10 cuts put to a hank, and then 20 of these hanks are required to make a bundle. It is by the bundle the yarn is sold. The fineness of wet spun linen yarn is reckoned by the number of cuts there are in 1 lb., but the fineness of dry spun yarn is usually reckoned by the weight of the "spindle" or "spangle" of 4 hanks; thus if a spindle of yarn weighed 2 lb. it would be called 2 lb. yarn. WEAVING: Linen yarn is frequently woven in the raw or "green" state and bleached afterwards; but as there is a great loss of weight from bleaching, the yarn for heavy cloths must be reduced in some way before they are woven. This is usually accomplished by boiling in alkalis, which makes a reduction of 10 to 15 per cent. The weaving of linen is conducted much in the same way as cotton weaving, but the yarn will not bear friction so well, though it is much stronger. It has very little elasticity, so that it requires strong machinery and all friction reduced as much as possible. Sometimes the yarn is used from the spinner's bobbins, but frequently in the hank state. It has to be wound on spools and warped on beams in the usual way, and then may be run from these on to the weaver's beam if strong yarn and in the green state, otherwise it must be dressed. "Dressing" is brushing the yarn over with some sort of a glutinous mixture, such as flour paste, to strengthen it, and lay all the loose fibres on its surface. Sizing or boiling in starch, as is practised in the cotton trade, does not do for linen yarn. The dressing is applied cold, and all the threads of yarn kept separate and not allowed to stick together. The yarn is run on to the weaver's beam in the dressing machine. The cloth is then woven, the greater portion of it being made into plain texture, though twills, fancy textures for towellings, and damasks for table linens also constitute a considerable part. A great quantity of unions are also made, as they are cheaper than pure linen, but are not equal to it in quality or strength. These are often termed "linen," and sold as such. When woven, the linen is either finished in the brown or loom state, or it may be bleached and dyed. It does not take dyes so well as many other fibres, and the colours, especially rich ones, look rather poor on it; but some shades of colour suit very well No fabric bleaches to such a rich pure white, and this, with its durability, if properly made, are its premier qualities. The linen trade in this country has its principal seats in and around Belfast in Ireland, and Dumfermline in Scotland. Originally Dublin used to be the centre of the Irish linen trade, but the trade worked northwards, and Dublin has but little of it left. All cloth made from flax or linen yarn is, broadly speaking, linen; but speaking definitely or in technical terms, only cloth of a plain texture, or with the warp and weft threads passing over and under each other alternately, is called linen.—T. F. B.

Linen Scroll. *See* LINEN FOLD.

Line of Action. The mathematical line (*q.v.*) along which a force is exerted.

Line of Continuation (*Music*). A horizontal line following the figures in a figured bass to indicate that the preceding harmony is to be continued for so long as the line of continuation is placed.

Liner (*Dec.*) A sable brush having a square top and hair about 2 in. long, used by coach and carriage painters for drawing lines on various parts of coaches. The term is also applied to a tool used by house painters, made of hoghair bristles set in tin ferrules, and usually called FITCHES. When made with a bevelled edge they are intended for drawing straight lines in decoration, and are then termed liners.

—— (*Eng.*) A tubular piece of metal placed inside a bearing, cylinder of an engine, etc., to compensate for the wearing away of the original surface.

Line Shafting (*Eng.*) The principal shafting running through a factory, from which the subsidiary shafts (countershafts, etc.) are driven.

Lines of Force. If a small electrically charged body perfectly free to move in any direction be placed in an electric field, it will move along a continuous definite path, which is usually a curved line. The tangent to the curve drawn from any point on the curve is the direction along which the electric force is acting at that point, and the whole line is termed a LINE OF FORCE. In a magnetic field similar lines of force may be drawn for the direction along which a single magnetic pole tends to move. The main properties of lines of force are as follows: (1) They run from a positive charge (or pole) to a negative one, always starting from one kind of charge (or pole) and finishing at another. (2) They converge or approach each other (though they never cut nor touch) in the parts of the field where the force is stronger, and diverge where the force is weaker. The number of lines in any part of the field may be taken as proportional to the force at that place. (3) The actual number of lines is not finite, since we may imagine a line running through every point in the space occupied by a magnetic field; but we may adopt any convenient convention connecting the number of lines and the actual electric or magnetic force at any point. This is settled by the units employed. The accepted system implies that both unit pole and unit charge correspond to 4π lines of force, magnetic and electric respectively. From this it follows that the electrical force at a point *in air* is equal to the number of electrical lines of force passing through a unit area surrounding the point, and at right angles to the lines, the same relation being true also for a magnetic field. If the medium is not air, its SPECIFIC INDUCTIVE CAPACITY (*q.v.*) or PERMEABILITY (*q.v.*) has also to be taken into account. (4) The lines are everywhere at right angles to the EQUIPOTENTIAL SURFACES; hence electrical lines of force ending on or starting from a conductor always cut its surface at right angles. (5) The arrangement of the lines is affected by the nature of the medium through which

they run. If a portion of material which has a higher SPECIFIC INDUCTIVE CAPACITY than the surrounding material be introduced into an electric field, lines of force crowd into it from other parts of the field; similarly the magnetic lines crowd into material of higher PERMEABILITY (*q.v.*), such as iron, when placed in the field.

Lingoes (*Silk Manufac.*) Lead drawn out to a form of wire or cable, cut into lengths of 7 to 10 in., varying in weight from 12 to 80 to the pound, and attached as weights to the lower ends of couplings carrying the MAILS in FIGURED HARNESS (*q.v.*)

Lining, Marking, *or* **Setting Out** (*Eng.*) Marking on a casting, etc., the principal points, centres, and lines from which the dimensions of the finished work are to be measured.

Lining Paper (*Dec.*) A white paper for hanging on walls and ceilings, as a foundation for the pattern paper.

Lining Papers (*Bind.*) *See* END PAPERS.

Linings (*Join.*) A general name in joinery for the internal work, finishings, etc., in a building.

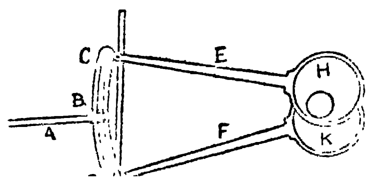
—— (*Met., etc.*) A coating of various refractory materials, such as fireclay, which is placed over the inner surface of furnaces, foundry ladles, etc., to prevent their destruction by fluid metal.

Link (*Eng.*) (1) Any connecting piece in a machine. (2) The slotted bar connected to the ends of the eccentric rods in LINK MOTION (*q.v.*)

—— (*Surveying*). *See* WEIGHTS AND MEASURES.

Linking Up (*Eng.*) *See* LINK MOTION.

Link Motion (*Eng.*) The reversing device used for working the slide valve in locomotives, marine engines, etc. The valve rod A, one end of which is attached to the slide valve, terminates at its other end in a block B, which slides in a slotted LINK CD. To the ends of this link are connected the rods E and F, to the ends of which are fixed the ECCENTRICS H and K (*q.v.*) The link CD can be raised or lowered by a system of levers attached to the link, so that either the upper eccentric rod E or the lower one F is in line with the valve rod A. Either eccentric can thus be made to drive the valve rod, the other one merely producing an oscillatory motion of the link which does not affect the valve rod; and if the two eccentrics are so fixed that they drive the valve in opposite directions (relatively to the stroke of the piston), then the engine can be reversed by raising or lowering the link, so that either E or F is in line with the rod A. In the position shown, termed MID GEAR, the valve remains at rest; by setting the link in an intermediate position, with the block B between the middle and end of the link, the time of cut-off, and therefore the expansion of the steam, can be varied; this is known as LINKING UP or NOTCHING UP. In GOOCH'S LINK MOTION the link is fixed, and B is connected to the valve rod by a hinged connecting rod: in this form the link CD is curved in the opposite direction. In ALLEN'S LINK MOTION a hinged valve rod is also used; when reversing, the link and the connecting rod are each moved in opposite directions: in this case the link CD is straight.



LINK MOTI

Linotype Composing Machine. *See under* TYPE SETTING MACHINES.

Linseed. The seed of the flax plant; much used for feeding cattle and for making linseed oil, linseed meal, etc.

Linseed Oil (*Dec., etc.*) The oil chiefly used by painters and decorators. *See* OILS.

Linstock (*Arms*). A pike, generally with branching arms on either side, shaped to hold the lighted match for firing the cannon; it also served the cannoneer as a weapon of defence. The linstock was used first in the sixteenth century; it sometimes consisted merely of a staff with a pointed end, for sticking in a deck or in the ground, the other end being fashioned to hold the match.

Lint. A name frequently applied to flax or the flax plant: also linen scraped into a soft substance, used for dressing wounds.

Lintel (*Build.*) The horizontal member of wood or stone forming the top or head over a door or window opening, and supporting the masonry or brickwork above.

Lion (*Her.*) The lion ranks first among the animals used in heraldry, and appears on many Royal shields. It is blazoned in numerous attitudes, each bearing a particular appellation. The teeth and claws are called their "arms"; they are generally armed gules unless otherwise specified.

Lioncels (*Her.*) When more than three lions are borne on one shield they are called "lioncels."

Lion Combattant (*Her.*) Two rampant lions placed facing each other; when back to back they are ADDORSED.

Lion Couchant (*Her.*) At rest or lying. The four legs stretched out on the ground head erect, facing dexters.

Lion Coward (*Her.*) As passant reguardant, but with tail between his legs. The crest of Arthur Tudor Prince of Wales was a lion coward.

Lion, Demi Rampant. The forequarters of a lion with the upper portion of its tail.

Lion Dormant (*Her.*) Asleep, head resting on or between forepaws, which are extended on the ground.

Lion Passant (*Her.*) The position of the lion when walking towards the dexter. Three paws on the ground, the fourth (dexter forepaw) raised; the tail curved over the back, and head looking straight in front.

Lion Passant Guardant (*Her.*) Similar position of body to passant, but with head facing spectator or affronté. *See* LEOPARD. Old armorists term the above a LEOPARD.

Lion Passant Reguardant (*Her.*) The same as passant, but with the head turned, looking back towards the sinister.

Lion Queue Fourchée (*Her.*) Having two tails, or double queued.

Lion Rampant (*Her.*) Stands erect on his hind-legs, with one of his forelegs elevated above the other; the tail is also elevated and the head in profile. The red lion in the royal arms of Scotland is a lion rampant.

Lion Rampant Guardant (*Her.*) Similar to rampant, only the head placed affronté—*i.e.* with the face towards the spectator.

Lion Rampant Reguardant (*Her.*) The same position as rampant, but with the head turned back or contourné—*i.e.* looking behind him.

Lion Salient (*Her.*) In the act of leaping or about to spring, hindlegs together on ground, forelegs together extended.

Lion Sejant (*Her.*) A lion sitting on his haunches, head erect, facing dexter.

Lion Statant (*Her.*) Standing on the four feet, the head in profile looking towards dexter; tail extended. The crest of the Duke of Northumberland is a lion statant.

Lion Statant Guardant (*Her.*) The same as statant, but with head affronté; tail extended, as in the well known crest of the Howards.

Lip (*Eng., etc.*) (1) The bent mouth of a ladle. etc. (2) A point or other part of the cutting edge of various tools.

Liparite (*Geol.*) A semi-crystalline rock of the type emitted as lava from the principal volcano of the Lipari islands. It agrees in chemical composition with that of the granites, and, like that rock, normally contains alkali felspar (usually Orthoclase) and some free quartz. Its highly cellular (or frothy) varieties form PUMICE, while its compact vitreous varieties are distinguished as OBSIDIAN. Plagioclase felspars, and one or more of the ferro-magnesian silicates, such as Biotite or Hornblende, may also be present, but in small proportion to the rest.

Lipase (*Chem.*) An enzyme which occurs in fresh pancreatic juice, in castor-oil seeds, linseed, poppies, etc. It has the property of resolving fats into glycerine and fatty acid, also of hydrolysing many other esters. Its action has been shown to be reversible; it can bring about the reunion of the alcohol and acid to reproduce the ester.

Liquefaction of Gases (*Phys.*) All the gases, with the possible exception of certain newly discovered and very rare elements, can now be liquefied. The essential feature of the methods in use consists in subjecting the gas to a sufficiently low temperature. Carbon dioxide, which can easily be liquefied by pressure alone at ordinary temperatures, since its critical temperature (*q.v.*) is 31° C., is commonly used to furnish one step in the production of cold. By allowing the liquid CO_2 to evaporate rapidly, solid CO_2 can be obtained, which, when mixed with ordinary ether (*q.v.*), forms a liquid whose temperature falls to − 77° C. If a vessel full of ethylene (*q.v.*) be immersed in this liquid, the gas becomes liquefied, and the liquid ethylene, on being allowed to evaporate, falls to a temperature of about − 150° C. To obtain the still lower temperatures necessary for the liquefaction of oxygen and nitrogen, a "regenerative" method is employed. The gas is compressed in a receiver which is strongly cooled; a stream of this gas is allowed to flow through a coiled tube surrounded by a jacket, the outside of which is maintained at a low temperature. At the end of the spiral is a small outlet, the size of which can be regulated by a valve. As the gas escapes from this orifice it expands, and in so doing becomes cooled. It then flows up through the jacket, and still further cools the spiral tube. Thus the stream of gas flowing through the spiral becomes colder and colder, until at last it is cooled down to its point of liquefaction, and drops of the liquid collect in a vessel placed beneath the outlet at the end of the spiral. Still lower temperatures may be obtained by utilising the rapid evaporation of gases liquefied by this method, and hydrogen may be liquefied and even solidified. It is believed that if liquid HELIUM (*q.v.*) could be produced in quantity, a temperature within 5° C. of the absolute zero could be attained.

Liquid. A liquid is a FLUID (*q.v.*) which is distinguished from a gas by the fact that it occupies a definite volume, whatever be the size of the vessel in which it is contained, and it always possesses a definite surface, which is horizontal when at rest.

Liquid Driers (*Dec.*) *See* DRIERS.

Liquids, Elasticity of (*Phys.*) Liquids show VOLUME ELASTICITY only (*q.v.*): that is, they do not offer resistance to forces tending to change their shape. *See* ELASTICITY OF VOLUME.

Liquorice (*Botany*). A demulcent drug derived from the fresh or dried rhizome of the plant *Glycyrrhiza glabra* (order, *Leguminosæ*).

Liriodendron (*Botany*). *L. tulipifera*, the tulip tree, belongs to the *Magnoliaceæ*. It is a native of North America, and is of value for its wood. *See* WOODS.

Liroconite (*Min.*) A hydrous basic aluminium and copper arsenate of very complex composition. Monosymmetric. Of a beautiful blue green colour. From Cornwall, Hungary.

Lisiere (*Silk Manufac.*) *See* LIZIER.

Lissajou's Figures (*Sound*). Figures produced by a spot of light, after reflection from two mirrors which are describing simple harmonic vibrations along two paths at right angles to one another. The mirrors are usually fixed to the tips of two large tuning forks, and the spot of light is either allowed to fall on a screen or observed through an eye-piece.

Listel (*Architect.*) *See* FILLET.

Listing (*Textiles*). *See* SELVEDGE.

Litharge (*Chem. and Dec.*) A common name for lead monoxide. *See* LEAD COMPOUNDS *and* DRIERS.

Lithia Mica (*Min.*) A synonym for LEPIDOLITE, (*q.v.*)

Lithium, Li (*Chem.*) Atomic weight, 7. A silvery white metal; melts at 186°. It is the lightest solid known (sp. gr. ·59); burns with bright white flame on being heated above its melting point in air; water converts it into the hydroxide, but much less energetically than in the case of sodium or potassium. Lithium has a characteristic spectrum consisting of one line in the red, and one weak line in the yellow; by means of its spectrum a quantity of lithium less than $\frac{1}{1000000}$ milligramme can be detected. On account of the extreme delicacy of this test it has been shown that lithium is a widely distributed element—thus, it occurs in sea water, in many mineral springs, in the ashes of many plants, *e.g.* in tobacco ash. The chief minerals containing it are triphyline (*q.v.*), petalite (*q.v.*), lepidolite (*q.v.*), and spodumene (*q.v.*) The metal is obtained from its chloride by electrolysis either of the fused chloride or of its solution in pyridine, using a carbon anode and an iron or platinum cathode. Lithium belongs to the same group of elements as sodium and potassium (Group I. of the Periodic System). Its salts bear a general resemblance

to those of sodium and potassium, the more notable differences being as follows: its chloride is strongly deliquescent, its sulphate does not form an alum, its carbonate and phosphate are far less soluble in water. Lithium salts (carbonate and citrate) are used in medicine for gout, because lithium biurate is a fairly soluble salt.

Lithography. The art or process of drawing or writing on a special kind of stone, or transferring drawings, designs, or writing to such stone, for the purpose of reproduction in ink. The process was discovered by Aloys Senefelder at Munich about 1798. Lithographic stones consist of a compact homogeneous slaty limestone, presenting a very smooth surface when polished. Suitable stones are obtainable from many countries, but the best come from Bavaria, the country where the discovery of the process was made. When the design has been produced upon the stone with special ink or chalk (or transferred to the stone), the surface of the stone is etched by means of a mixture containing about two parts of nitric acid, the ink or chalk design being unaffected by the etching medium. The result is that the design is elevated above the surface of the stone to an almost imperceptible degree. The next process before printing is the removal, by means of a solvent, of the whole of the material employed to effect the design. The stone is then wetted. The *design* is unaffected by the water and is capable of receiving printing ink from the roller, whereas the etched portion when damp will not take up the ink. The desired impression can then be obtained by passing the stone through the press. CHROMO-LITHOGRAPHY requires the employment of as many different stones as there are various tints or colours, one stone being printed from after another upon the same sheet, the whole of the printings when completed fitting and blending together and giving the required result. Much success in colour printing has recently been obtained by ALGRAPHY, a process in which aluminium is substituted for the lithographic stone.

Lithopone (*Dec., etc.*) The name given to a white pigment of Continental manufacture, of which Orr's Zinc White (*q.v.*) is the prototype. Also spelled LITHOPHONE.

Litmus (*Chem.*) Rounded or cubical blue granules consisting chiefly of chalk and gypsum, and containing only a little of the real colouring matter. The colouring matter occurs in various lichens (*Roccella tinctoria*) which grow in Norway, Sweden, the Canary Islands, and on the shores of the Mediterranean Sea. The lichens are dried, powdered, and allowed to ferment for several weeks in presence of urine or ammonia. During the fermentation a substance, ORCIN, is formed, among many others. The orcin, in presence of air and ammonia, forms ORCEIN, which yields litmus by further fermentation in presence of ammonia. The colouring matter so obtained is mixed with chalk and gypsum. Litmus is a mixture of substances, the true colouring agent being a substance called AZOLITHMIN, of unknown constitution. Azolithmin is a dark brown amorphous solid, sparingly soluble in water, insoluble in alcohol, soluble with blue colour in alkalis, insoluble in strong acids. It can be prepared from commercial litmus by extraction with cold water, acidifying with hydrochloric acid, and evaporating with sand to dryness. The dry powder is spread upon large filters, and washed successively with hot and cold water, and again dried. The dry powder is now washed with hot water containing a little ammonia. The solution, which now contains the azolithmin, is neutralised, and it is ready for use. The azolithmin can be obtained from it by diluting and acidifying with sulphuric acid, when the colouring substance is precipitated. Good litmus solution is a very sensitive indicator for acids and alkalis; but alkaline carbonate must be titrated boiling, so that carbon dioxide, which reacts acid to litmus, does not remain in solution. Litmus solution kept in closed bottles changes in colour, owing to the action of anærobic bacteria; it regains its colour on access of air, or will retain it in a closed bottle if a little thymol is added. Litmus papers are prepared by soaking unglazed paper in litmus solution, rendered just alkaline for blue papers and just acid for red papers, and afterwards drying.

Litre. *See* WEIGHTS AND MEASURES.

Little Masters (*Art*). The term applied to a group of German artists of the sixteenth and seventeenth centuries, so called from the smallness of the prints they executed. They were chiefly influenced by Dürer, and included amongst their number Aldegrever, Burgkmair, and Altdorfer.

Littoral Conditions (*Geol.*) The geographical conditions which occur in the zone extending from high water mark outwards to a depth of a few fathoms. It is generally understood to refer to the marginal zones of the sea; but it is not infrequently applied also to the marginal zones of lakes. The Littoral zone is usually regarded as the belt over which marine life is most fully developed, and it also coincides with the chief zone of marine erosion.

Littoral Deposits (*Geol.*) Rock materials which have been formed or have accumulated close to the shore line, in contradistinction to PELAGIC or THALASSIC deposits formed under conditions of deeper water. They are usually either sands and gravels, or else their compacted equivalents, sandstone and conglomerates. They are generally characterised by containing the vestiges of shore animals and plants.

Lituus (*Archæol.*) The staff or wand, with one end curling round, used by Roman augurs. The prototype of the bishop's crozier.

Live (*Elect. Eng.*) A conductor is said to be live or alive when a current is flowing in it, or when it is at a high potential.

—— (*Eng.*) A moving part of a machine is sometimes termed live or alive in contradistinction to the fixed parts.

Live Load (*Eng.*) A weight or load on a structure which varies either as regards amount or position.

Live Ring (*Eng.*) A circular channel under a TURNTABLE (*q.v.*), in which are a number of rollers, called LIVE ROLLERS, which support the weight of the table, and thus form a kind of large roller bearing; a similar device is used with large revolving cranes.

Live Steam (*Eng.*) Steam which has not been expanded, as distinguished from exhaust steam.

Lixiviation (*Chem.*) The process of extracting, by a suitable solvent, the soluble product of a chemical change which has been effected in a substance or mixture of substances by heating to a high temperature. The solution obtained is often called a LYE. For an example *see* the Leblanc Process, *under* ALKALI.

Lizier, Lisiere, *or* **Edge** (*Silk Manufac.*) The selvedge of a cloth, usually made either gros or twill, and warped on a bobbin separate from warp roll. It is frequently striped in a special arrangement of colours, by which certain qualities and makes of cloth are known.

Load (*Elect. Eng.*) The output, in watts, required from a dynamo or other electrical plant or machinery, *i.e.* the electrical power which the plant is required to furnish to the circuit which it supplies.

—— (*Eng.*) (1) The weight supported by a structure. (2) The power furnished by an engine, etc., under any given circumstances.

Load Curve (*Elect. Eng.*) A curve showing the total power furnished at each period or instant throughout the day.

Loading. A term signifying the addition of china clay and other minerals to pulp in order to produce a paper suitable for printing illustrations, *i.e.* an ART PAPER.

Loadstone. *See* LODESTONE.

Loam (*Build.*) A mixture of sand and clay.

—— (*Foundry*) A mixture of sand, clay, and some material of a fibrous nature, used for making cores or forming moulds by the use of a loam board or striking board, instead of by the use of a pattern. Occasionally a LOAM PATTERN is made and used instead of an ordinary wooden pattern; this process is used in the case of large objects of circular section, and the pattern is formed in much the same way as a core.

Loam Board (*Foundry*) A board whose edge is cut to the contour or outline of some casting; it is used for forming a core, loam mould, or loam pattern, in lieu of using a wooden pattern. A simple cylindrical casting, large iron piping, etc., can be moulded in this way, the core being formed separately and inserted in the ordinary way. A loam mould requires to be dried artificially before the metal is poured.

Loam Brick (*Foundry*) A block of dried loam used in building up the larger portions of a loam mould.

Loam Mill (*Foundry*) A kind of mortar mill used in the foundry for grinding and mixing loam.

Loam Mould (*Foundry*) *See* LOAM *and* LOAM BOARD.

Loam Pattern (*Foundry*) *See* LOAM.

Lochrian (*Music*) *See* MODES.

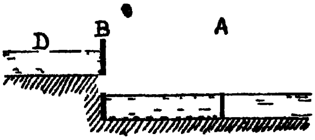
Locker. A strong box, chest, or compartment secured by a lock; a small cupboard, especially one under a seat.

Locker Rack (*Civil Eng.*) *See* MOUNTAIN RAILWAYS.

Lock Nut (*Eng.*) A thin auxiliary nut screwed on the top of an ordinary nut to prevent the latter from working loose.

Lock Rail (*Joinery*) The rail of a door on which the lock is fixed. Usually the middle rail.

Locks (*Civil Eng.*) A device used for transferring a vessel between two parts of a stream, canal, or harbour, at different levels. Two lock gates, A and B, enclose a space E, whose bottom is on a level with the lower part of the channel. To pass a vessel from C to D, it is first admitted by opening the gate A, the water being made level in E and C by a sluice in A. The gate A and the sluice are closed, and a sluice in B opened until the water in E is level with that in D, when the vessel can pass into the upper channel. Locks are always used when there is an adequate supply of water in the upper part of the channel.



LOCKS

Lock Saw (*Carp., etc.*) *See* KEYHOLE SAW.

Loco (*Eng.*) A common abbreviation for LOCOMOTIVE.

—— (*Music*) In the pitch as written, used after 8ve or 8va bassa, to show that the written pitch is to be resumed.

——, **Loco Plant, Loco Weed** (*Botany*) A leguminous plant (a species of *Astragalus*, found in the west and south-west of the United States. When eaten by cattle it causes *loco disease*, an affection of the brain.

Locomobile (*Motor Cars*) A name given to a light class of steam cars of American make.

Locomotive (*Eng.*) Usually a railway engine; also applied to traction engines (*q.v.*), certain forms of motor car (especially steam cars), and to electric motors mounted on an independent vehicle for drawing electric trains.

Locomotive Boiler (*Eng.*) *See* BOILERS.

Locomotive Crane (*Eng.*) A power crane capable of running along a line of rails propelled by its own engine.

Loculus, *pl.* **Loculi** (*Archæol.*) A small chamber or recess in ancient tombs for the reception of a body or an urn. *See* CATACOMB.

Lodes (*Geol. and Mining*) Originally a Cornish miners' term for mineral veins containing one or more of the ores of the metals, and now used in that sense generally. The lodes usually occupy the intervening space between the opposite walls or "cheeks" of a fissure. In nearly all cases this fissure constitutes part of a fault or dislocation, of the country rock on one side relative to that on the other. The ores, and their accompanying gangue or "rider," usually occur in a very irregular and sporadic manner throughout the height and length of the lodes, and their extent in a longitudinal direction generally much exceeds that from below upwards.

Lodestone *or* **Loadstone** (*Elect.*) The natural magnet, consisting of the oxide of iron, Fe_3O_4, or MAGNETITE (*q.v.*). The word lodestone means "leading stone," from its power of acting as a compass needle, and "loadstone" is an incorrect spelling.

Lodgings (*Hygiene*) *See* HOUSES LET IN LODGINGS.

Loess (*Geol.*) A geologically recent deposit of loam, occurring over wide areas in some parts of Europe, and on a still more extensive scale in China. In the latter country the Loess appears to be a deposit which has arisen from the long continued deposition of dust transported from desert regions by the wind. It is considered by many persons that the European Loess is due, in like manner, to dust deposited under steppe conditions. The brick earths of the south-east of England are supposed by many to have been formed in this way, but the fact that they contain large boulders, and show evidence of crumpling, such as is produced by floating ice, seems to render that view untenable.

Log. A LOGARITHM (*q.v.*)

—— (*Carp., etc.*) A large piece of timber, either in its original shape or roughly dressed by the axe, but not sawn.

Logarithm. A COMMON LOGARITHM of a number is the index of the power to which the number 10 must be raised to give the number; thus 10 must be cubed or raised to the power 3, to give 1,000; hence the common logarithm of 1,000 is 3. The number 10 is called the BASE of the common logarithms. NATURAL or NAPIERIAN LOGARITHMS are calculated to a different base, the series denoted in mathematical books by *e*. The sum of this series is 2·71828 . . . The natural logarithm of a number can be found by multiplying the common logarithm (taken from tables of logarithms) by 2·30258.

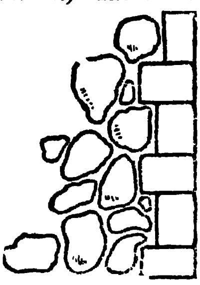
Loggia (*Architect.*) An arcade on the façade of a building, forming a gallery open to the air on one side.

Logotype (*Typog.*) Two or more letters in their normal form, or sometimes a word, cast on one body. *Cf.* LIGATURE (*Typog.*)

Logwood (*Botany*). The dye substance HÆMATOXYLIN (*q.v.*) is found in the heartwood of the stem of *Hæmatoxylon pechianum* (*Leguminosæ*). *See also under* DYES AND DYEING.

Long (*Music*). *See* NOTES.

Long and Short Work (*Architect.*) The name given to the ashlar quoins used in the rubble walling of Anglo-Saxon work. The quoins were formed of flat and upright courses alternately. *See* BLOCK AND START.



LONG AND SHORT WORK.

Long Column (*Eng.*) A column of material whose length is more than twenty times its diameter. Such a column gives way by bending, whereas a short one gives way only by crushing.

Longitude, Celestial (*Astron.*) *See* LATITUDE AND LONGITUDE, CELESTIAL.

——, **Libration in** (*Astron.*) *See* LIBRATION.

Longitudinal Elevation. A side view of a structure.

Longitudinal Section. A view showing a section through an object from end to end.

Long Letters (*Typog.*) Letters extending above or below the alignment of the small letters, *e.g.* b, f, g, h.

Long Primer (*Typog.*) Type of a size between small pica and bourgeois. *See* TYPE.

Longwall System (*Mining*). *See* MINING.

Loofah (*Botany*). The loofah, used as a natural flesh brush, consists of the vascular network of the fruit of a plant of the cucumber family, *Luffa ægyptica* (order, *Cucurbitaceæ*).

Loom. The machine used for combining and interlacing the warp and weft threads so as to form cloth. Each loom is fitted up to suit the particular class of work required—that is, either with a tappet, dobby, or Jacquard shedding motion. A loom with one shuttle box at each end of the sley is called a plain or stripe loom, and would only admit of one colour or thickness of weft being inserted with the warp. This combination would be called a plain or a stripe cloth, according to the weave. Some looms are fitted up with more than one shuttle box at the end of sley, and are termed multiple box or check looms. These are capable of producing various coloured patterns in the cloth, known as check cloths. A loom is lightly or heavily constructed to suit the class of work which it is required to produce. The hand loom is very seldom used in the cotton trade, except for pattern weaving and experimental purposes. Power looms are worked in factories principally by steam motive power, and for good working a steady motion is requisite. The power loom is automatic so far as regards its essential movements for the production of cloth, which are: (1) Opening the shed or making a division in the warp threads for the shuttle to pass through; (2) picking through the shuttle, which carries the weft; (3) beating up the weft. The first is accomplished by the shedding motion; the second by the picking motions, which are of two kinds—*viz.* (*a*) overpicks, (*b*) underpicks; the third by the crank and sley each time a pick of weft is inserted by the shuttle. Auxiliary motions in the form of taking up and weft stop motions are also attached, these being absolutely necessary for the production of perfect cloth. The taking up motion automatically regulates the closeness of the weft threads or picks as the cloth is woven, and to a certain extent determines the quality. The weft stop motion immediately stops the loom if the weft in the shuttle breaks or becomes exhausted before the weaver perceives it. The recognised practice in the trade at the present time in England is for a weaver to attend from four to six looms, the duties being to replenish the weft in the shuttle as it becomes exhausted during weaving, piece up broken warp threads, and attend to other minor details. Efforts are now being made by some manufacturers to get weavers to attend from six to eight looms by attaching a warp thread stop motion to each. With this system a weaver must depend on the efficiency of the stop motion to produce perfect cloth. Several forms of automatic shuttling or shuttle changing motions are now being tried for plain work. No results of a definite character have yet been arrived at in England, although a large number are in operation in America. The new motion allows a weaver to attend from twelve to twenty looms. A considerable amount of skill is taken from the weaver and put into the loom mechanism. The following are the chief automatic weft supply looms on the market: (1) Northrop, (2) Hattersley, (3) Harriman, (4) Baker Kip, (5) Cowburn. DESCRIPTION OF ORDINARY POWER LOOM.—The warp beam C is placed in brackets behind the loom. All the warp threads are passed over back rest rail D in a broad sheet and split up by lease rods E, which serve to keep the threads in their proper order, before they pass through the eyes in healds 1 and 2. For a plain weave the threads would be drawn alternately through the eyes on healds 1 and 2, and again passed through the reed F, two threads in a dent or split, which is held in position by sley G and handrail H, they in turn being secured to sley sword L, working on rocking rail M as a fulcrum. When the warp is in process of interlacing with the weft, the cloth will be formed at K and pass over the breast beam N round feed roller P, and on to cloth roller R. The whole stretch of warp from C to N is kept at suitable tension by chains and weights round the warp beam C. An oscillating

motion is imparted to the sley by means of connecting rod S from crank T, which is on the main driving shaft of the loom. Immediately below the crank shaft is fixed tappet shaft V, on which are placed the plain tappets or cams A and A'. This shaft only makes one revolution for two of the crank shaft, consequently the tappets come in contact with their own levers B and B' alternately. The simple operation of weaving is performed as follows: As the tappets A and A' revolve, they operate on levers

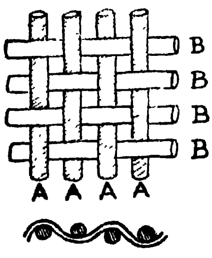


Fig.

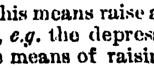

Fig. 3.

B and B', and by this means raise and depress healds 1 and 2 alternately, *e.g.* the depression of lever B and heald No. 1 is the means of raising heald 2 through top roller W. All threads drawn through the eyes of healds No. 1 are raised, and all threads drawn through the eyes of healds No. 2 are depressed. By this means

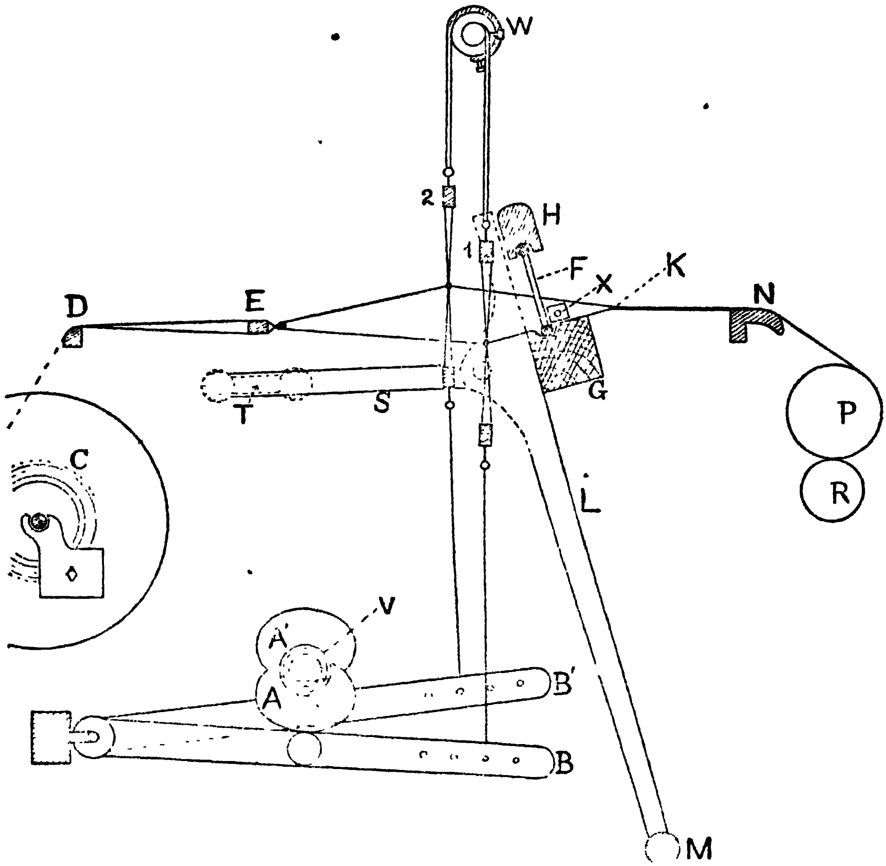

Fig. 1.

a "shed" is formed, and when full open the shuttle X carrying the weft is "shot" or "picked" through. By the time the shuttle has passed through the shed and reached the box on the other side of sley, the loom crank will have moved the sley to its most forward position, and by means of the reed the weft will be forced to the "fell" of the cloth at K. Before

Fig. 4.

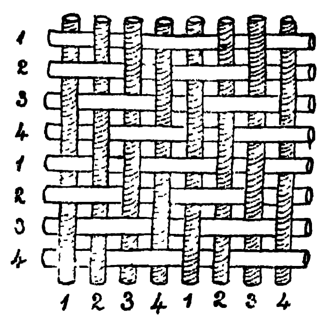

Fig. 5.

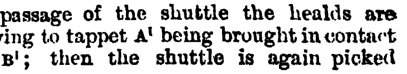


the return passage of the shuttle the healds are reversed, owing to tappet A' being brought in contact with lever B'; then the shuttle is again picked

through, and the weft afterwards beaten up as before. The fact of all odd threads being lifted when even threads are down, and *vice versâ*, each time a "pick" of weft is inserted, enables a woven cloth to be produced which is very firm and strong, considering the amount of material which may be put into it. The ordinary method of "darning" gives one an idea of a plain weave, a diagram in plan being here given at fig. 2 and a section at fig. 3. When the warp threads are required to be put closer together in the reed, and a different method of interlacing is required, such as a twill weave, more shafts of healds are necessary. This involves the use of differently constructed tappets, which are mostly worked from counter shafts, actuated from the tappet shaft V or by special gearing from the crank shaft at one end of the loom. A three end twill would require a three leaf tappet, a four end twill would require a four leaf tappet, and so on. Fig. 4 shows enlarged weave plan of a four end twill, produced by a four leaf twill tappet, working four healds in succession for two picks up and two down. Fig. 5 is sectional view showing one pick of weft intersecting with warp threads. Small figured weaves are usually produced by means of the dobby machine, the tappets being dispensed with. When the patterns to be produced are beyond the capacity of the dobby, then the Jacquard machine is used.

Looming (*Meteorol.*) An appearance allied to MIRAGE (*q.v.*), by which distant objects become visible at a greater altitude than their true one, or actually inverted, over their actual position. It is probably due to a layer of hot and rarefied air some distance above the level of the ground.

—— (*Textile Manufac.*) *See* LOOM.

Loop Yarn (*Textile Manufac.*) A fancy yarn on which curls or loops are formed on the twisting frame. It is a yarn extensively used in fancy fabrics, and also in fabrics with a curly surface.

Loors (*Mining*). Fine material or sludge left as refuse from the washing of tin ores.

Loose Centres (*Eng.*) Supports resembling a pair of POPPET HEADS (*q.v.*), used to hold cylindrical objects while marking out, or while certain operations are being carried out in the planing or slotting machine.

Loose Coupling (*Eng.*) A coupling (*q.v.*), which can readily be disengaged or thrown out of gear.

Loose Eccentric (*Eng.*) An eccentric which rides loose on the shaft, but is prevented from turning completely round by two fixed stops. When in contact with one of these it drives the engine forward; by bringing it in contact with the other stop the engine is reversed.

Loose Gland (*Eng.*) A ring used for making a watertight joint in iron piping. It serves to force a rubber ring into the socket, and is kept in place by bolts.

Loosening *or* **Rapping** (*Foundry*). Tapping a pattern which is being moulded in order to loosen it slightly in the sand and facilitate its withdrawal.

Loosening Bar (*Foundry*). A bar of iron used for loosening or rapping a pattern.

Loose Pieces (*Foundry*). Parts of a complicated pattern which can be detached from the main portion to facilitate withdrawal from the mould.

Loose Pulley (*Eng.*) A pulley which can turn freely on its shaft; it is placed alongside a fixed or driving pulley, so that the driving belt can be shifted on to it when the machinery driven by the belt is to be stopped.

Lorry. A flat truck.

Loss (*Eng., etc.*) A part of the energy supplied to a machine which is dissipated by friction and is not converted into useful work.

Lost Ampères (*Elect. Eng.*) The portion of the current generated by a Shunt dynamo, which flows through the coils of the field magnets instead of through the external circuit. In a good machine this portion is usually only a very small fraction of the total current generated.

Lost Volts (*Elect. Eng.*) That portion of the total E.M.F. generated in a Series dynamo which is required in order to send the current through the coils of the field magnets. The voltage thus lost is very small in a good machine.

Lost Wax Process (*Founding*). A method of bronze founding in which a core is covered with a wax model of an object of which a casting is required, the wax being made of the same thickness as it is intended the metal shall be. When the model is complete, the wax is covered with a porous clay, and the whole baked in a pit; the wax, of course, melts during the process, and runs off through openings left for the purpose. The space that was occupied by the wax now forms the mould for the metal.

Lotus Capital (*Architect.*) Three types of Egyptian capital—the campaniform, the clustered lotus bud, and the plain lotus bud capitals—were derived from the lotus flower in different stages of development. The outline of the plain lotus bud capital is similar to that of the clustered lotus bud capital, but its horizontal section is a circle, whereas that of the latter is a series of convex segments. *See* CLUSTERED LOTUS BUD CAPITAL, CAMPANIFORM CAPITAL, HATHOR HEADED CAPITAL, *and* PALM CAPITAL.

Lotus Flower (*Architect.*) An Egyptian water lily. This flower, conventionally treated, was freely used in Egyptian architecture.

Louver (*Archæol.*) A domed turret or lantern with lateral openings, fixed on the roof of the hall in a mediæval building in order to carry off the smoke which rose from the open hearth.

—— *or* **Louvre** (*Build.*) Strips of wood or other material running across an opening, the plane of each strip being inclined to the vertical plane, and its lower edge overlapping the strip below it, but not touching it. The spaces thus left between the strips are available for ventilation, but rain, etc., is excluded. Used for shutters, ventilators, etc. The spelling LOUVRE is incorrect, though it is commonly used.

Louvered Ventilator (*Build.*) A frame with inclined boards, strips of glass, or other material (louvers), arranged so as to admit air but exclude rain. *See also* LOUVER.

Louvre. The name of the palace in Paris in which are placed many of the finest examples of art possessed by the French nation.

—— (*Build.*) The common spelling of LOUVER (*q.v.*)

Low (*Meteorol.*) A term generally applied to cyclone centres in contradiction to HIGH, the centres of anticyclones.

—— (*Print.*) Used to imply that parts of a printed sheet do not show up clearly, *e.g.* in the case of worn type. *Cf.* HIGH.

Lower Case (*Typog.*) The case that contains the small letters and spaces. *Cf.* UPPER CASE.

Lowestoft (*Pot.*) A small manufactory of porcelain was established at Lowestoft about the year 1756. The wares produced were never of high standard or of great importance. So-called "Lowestoft" china is almost invariably of Chinese manufacture. The factory was closed about 1804. Lowestoft china is of poor quality, and the ornamentation of it is slight and inferior.

Low Flash Oil. Oil whose vapour becomes spontaneously ignited at a comparatively low temperature. *See* FLASHING POINT.

Low Moor Iron (*Met.*) One of the best qualities of wrought iron, made at Low Moor in Yorkshire.

Low Pressure Cylinder (*Eng.*) The larger cylinder of a compound engine, in which the steam undergoes its final expansion before escaping. *See* STEAM ENGINE.

Low Red Heat. A temperature of about 1300° F. (700° C.)

Low Relief (*Sculp.*) *See* BAS-RELIEF.

Low Warp. Tapestry in which the warp (*q.v.*) takes a horizontal position during the process of weaving. This facilitates its manufacture, but the result is not supposed to equal high warp tapestry. *See* HIGH WARP.

Lozenge (*Her.*) A diamond shaped, four sided charge set perpendicularly on a shield. The shield of an unmarried woman or of a widow is of this shape. A shield divided by diagonal lines crossing forms a pattern called lozengy.

Lozenge Moulding (*Architect.*) An enriched moulding, used in Norman architecture, consisting of a repetition of lozenge shaped forms.

Lubricants. The theory of lubrication is the interposition between two surfaces which rub together (by reason of the motion of one or of both of them) of a substance which has a smaller co-efficient of friction with both the surfaces concerned than they have one with another. Lubrication, then, is using something to diminish friction, and therefore waste of power, and, what is of even more importance, heating of the surfaces and possible consequent seizure from expansion and stoppage or breakage of the machinery. Experience has shown that fats and petroleum are the best lubricants, with certain special exceptions, the chief of which is graphite, used for wooden gearing which would absorb grease or a liquid lubricant. To know what lubricant to use in a given case is very important, and many different kinds and combinations have been tried for various purposes, with the result that a large number of lubricants are in use. The prime requisite of a lubricant is that it shall diminish friction, as above stated. It follows from this that drying oils such as linseed or poppy oil, which become sticky and resinous by exposure to the air, are unsuitable. The lubricant must remain between the surfaces during the motion. Hence for heavy bearings a thicker lubricant is required than for light ones, which, although they would diminish friction more, would be squeezed out from the bearing. The speed at which the axle is driven has also an important influence on the choice of a lubricant. Other things being equal, the higher the speed the thinner and less in specific gravity must the lubricant be. The factor of time comes in here. A very heavy but slow running axle can be and must be fed with a comparatively viscid lubricant, and there is time to overcome the cohesion of the oil particles so that they slide over one another and over the lubricated surfaces. If the same axle were run at a high speed, internal stresses would be developed in the oil layer, the overcoming of which would necessitate a large amount of power. It will now easily appear that it is difficult to find a good lubricant for heavy axles run at a high speed, and that in any case a compromise must be effected, and the lubricant fitted as nearly as may be both to the weight and to the speed of the axle. Of course, light, fast running axles, such as cotton mill spindles, are easily provided for, as are heavy and slow moving axles. Another important point is the temperature at which the lubricant has to do its work. This is why oils for bearings are so different from the oils used for lubricating pistons and stuffing boxes in steam and gas engines. It is quite evident, to begin with, that an oil which might be too viscid at ordinary temperatures might be just right or even too fluid when subjected to the heat of steam or gas explosion. Again, the chemical constitution of the lubricant must not undergo an injurious change, owing to the temperature or the action of steam or hot gases. Steam is a most energetic chemical reagent at high temperatures. One effect of high temperatures is to carbonise the fat. If that happens, the function of lubrication is seriously interfered with, and in a gas engine carbonisation is extremely likely to happen. High pressure steam decomposes fats into glycerine and fatty acids, whereby not only is a part of the lubrication lost, but chemical action ensues between the fatty acid and the lubricated surfaces which soon leads to clogging and imperfect fitting. The glycerine is carried away into the exhaust. It is obvious that for high temperatures oils and fats are quite unsuitable, and no better lubricants are known for cylinders than heavy petroleum oils. These are extremely stable chemically, have low co-efficients of friction, and are fluid enough at the high temperatures with which they meet. They cannot turn acid, and are as free from chemical action, whether on steam or anything else, as can be desired or hoped for. Many cylinder oils on the market are mixtures of mineral oil with ordinary fat. These should be shunned, as the presence of the mineral oil does not prevent the occurrence of the difficulties above detailed as a result of the action of high temperatures on animal or vegetable fats. The dark cylinder oils are an intermediate fraction of petroleum, the light oils having been removed by distillation, and the solid ingredients of the mineral oil by cooling. They vary greatly in usefulness, as well as in colour and consistency. They have a low specific gravity, averaging about ·9, and a high flash point (260° to 285° C.) The pale cylinder oils have a higher specific gravity (about ·925), and a considerably lower flash point (often as low as 220° F.) They are inferior to the dark oils in all respects. As regards the tests of a cylinder oil, it should, in the first place, contain no volatile constituents. Its weight ought to remain constant at the boiling point of water or somewhat higher for

many hours. The heaviest oils evaporate slowly below their boiling points, but even after thirty-four hours at 110° C. the loss should be less than 1 per cent. The flash point should be fairly high, not less than about 250° C., and the viscosity must be considerable, and should not be greatly lessened by the temperature that is known to prevail in the cylinder to be lubricated. Theoretically the specific heat should be as high as possible; but the point is of no practical importance, seeing the small differences between the specific heats of different oils, mineral or otherwise, and the small quantities that are used. As regards lubrication at ordinary temperatures, graphite or talc is most useful for very heavy, slow running axles. Both should be mixed with a solid or liquid fat, according to the temperature of the workshop. Tallow is excellent for warm shops. Lard, tallow, castor oil, heavy petroleum oils, or mixtures of them all answer well. Probably any vegetable or animal fat is improved by petroleum, as the mineral oil keeps the bearings clean. In this connection it may be mentioned that all fats must be scrupulously freed from every trace of membrane or tissue if they are to be used as lubricants. Such impurities are especially common in solid fats, and a number of samples should be examined under the microscope on a heated stage. When the fat on the slide is fused, any fragments or skin can be at once detected, and show that the stuff is unfit for use. For high speeds under heavy pressure, rape and lard oils are largely used, generally mixed with heavy or light petroleum oils, according to the working temperature. For rapid, light running machinery, sperm oil is the favourite lubricant, but olive and rape are much used, both alone and mixed with the lighter petroleum oil. In general, two different lubricants should be used for a machine, for it is almost invariably the case that different parts of it run under different pressures and at different speeds.

Lubrication (*Cycles*). An exposed chain is best treated with finely crushed graphite or black lead, freed from grit and well rubbed on. All other parts should be lubricated with any good machine oil.

Lubricator (*Eng.*) A receptacle for lubricants. It may be a simple vessel communicating with the bearing, etc., by a tube or channel, or it may be supplied with some device for pouring or forcing a stream of oil into the bearing.

Ludlow Rocks (*Geol.*) A general term for the upper third subdivision of the Silurian Rocks, taken from the name of the town where these rocks were first studied. Of late years the extended study of the rocks on this horizon has led to the suggestion that their classification should be remodelled, and that the term DOWNTONIAN, which is preferable for many reasons, should be employed, in place of the older name, for all the rocks from the top of the Ledbury Shales to the base of the Leintwardine Flags which underlie the Aymestry Limestone. The Lower Ludlow Shales are thus left in another division, which is termed the SALOPIAN.

Lug (*Eng.*) A projecting portion of a casting, etc., by means of which it can be fixed in position, *e.g.* by bolts passing through.

—— (*Plumb.*) *See* EAR.

Lugs (*Cycles*). *See* CYCLES.

Luminosity (*Phys.*) (1) The power of giving out light. (2) The amount of light furnished by a particular source.

Luminous Paint (*Chem.*) A paint which emits light in a dark room. If some bits of phosphorus are allowed to stand in olive oil in a bottle which is kept in a warm place for two or three days, the oil dissolves a little phosphorus, and when it is painted on an object, the latter is visible in a dark room, and will remain visible till the phosphorus is oxidised. A totally different paint may be made by mixing various phosphorescent sulphides or oxides with oil, and using this as a paint. *See* BOLOGNIAN PHOSPHORUS *and* CALCIUM SULPHIDE.

Lunar Bows (*Meteorol.*) *See* RAINBOWS.

Lunar Caustic (*Chem.*) A common name for SILVER NITRATE. *See* SILVER COMPOUNDS.

Lunar Distances (*Astron.*) A method of determining longitude by means of the measurement of the apparent distances of stars from the lunar disc.

Lunation (*Astron.*) The time between one new moon and the next. *See also* SYNODIC MONTH.

Lunette (*Architect.*) A window formed in a domical ceiling.

Lunga Pausa (*Music*). Long pause.

Luni-Solar Precession (*Astron.*) A slow retrograde motion of the equinoctial points upon the ecliptic. *See also* PRECESSION.

Lusingando (*Music*). Coaxingly, tenderly.

Lustre. A large ornamental chandelier.

—— (*Min.*) The lustre of minerals is a property of importance in classification. Six varieties of lustre are usually referred to. They are:

(1) METALLIC (Galena or Pyrites).
(2) VITREOUS or glassy (Quartz, Rocksalt).
(3) RESINOUS (Amber, Pitchblende).
(4) PEARLY (Talc).
(5) SILKY (Fibrous Gypsum).
(6) ADAMANTINE (Diamond).

Lustring *or* **Lutestring** (*Silk Manufac.*) A plain silk fabric woven as tabby, the weft used being bright, to give lustre.

Lute (*Met.*) Refractory material, such as fire-clay, used for making a close joint in furnaces, covers of crucibles, etc.

Lutestring (*Silk Manufac.*) *See* LUSTRING.

Lutidines (*Chem.*), $C_5H_3(CH_3)_2N$. A name given to the dimethyl pyridines, of which there are six; some of them occur in bone oil. *See* PYRIDINE.

Luxembourg. The Palace of the Luxembourg in Paris contains an Art Gallery, in which are exhibited works by many famous modern artists.

Lychees (*Botany*). The Chinese plant *Litchi chinensis* (order, *Sapindaceæ*) produces an edible nut containing a fleshy aril around the seed. The fruit in a dried state is imported into this country.

Lych Gate (*Architect.*) *See* LICH GATE.

Lycine (*Chem.*) Another name for BETAINE (*q.v.*)

Lycopodium (*Botany*). A fern plant *Lycopodium clavatum* (order, *Lycopodiaceæ*), with a superficial mosslike appearance ("Club moss"). The resinous spores are used in medicine and as a coating for pills. In Sweden doormats are made from the plants.

Lydian (*Music*). *See* MODES.

Lye (*Chem.*) A very general term for various solutions used in chemical trades, *e.g.* a solution of an alkali. *See also* LIXIVIATION.

Lying Press (*Bind.*) A strongly made press actuated by two screws, used for various purposes, *e.g.* holding a book while the edges are being cut or while the back is being shaped.

Lymphatics (*Zool.*) A system of vessels which traverse the body, finally passing to the large veins near the heart. Their function is to carry back to the blood the waste products of the tissues.

Lysine (*Chem.*), *ae*-diaminocaproic acid, $CH_2NH_2CH_2CH_2CH_2CHNH_2COOH$. A white crystalline solid obtained among a large number of other products on boiling albumins with concentrated hydrochloric acid. It is dextrorotatory. According to some it is the parent substance of the ptomaine Cadaverine, which forms when dead bodies putrefy.

Lysol (*Chem.*) A disinfectant consisting of a solution of crude cresol in soft soap.

M (*Elect.*) Commonly used as a symbol for MAGNETIC MOMENT (*q.v.*)

m (*Elect.*) A symbol commonly used for the strength of pole (*q.v.*) of a magnet.

μ (*Elect.*) The symbol for PERMEABILITY (*q.v.*)

—— (*Phys.*) The symbol for a MICRON, the thousandth part of a millimetre.

$\mu\mu$ (*Phys.*) The symbol for the millionth part of a millimetre, *i.e.* a thousandth of a MICRON (*q.v.*)

Ma (*Music*). But, *e.g. Ma non troppo*, but not too much.

Macabre (*Art.*) A term applied to a subject in which there occurs a representation of Death, *e.g.* in the form of a skeleton, etc.

Mace (*Archæol., etc.*) A staff or bludgeon, and originally the special weapon of prelates and of the King's sergeants-at-arms. A brass in Wandsworth parish church of one Nicholas, a sergeant-at-arms of Henry V., is unique in showing the mace suspended from his girdle in the place generally occupied by the misericorde. Most corporate bodies now possess a mace, used as an insignia of office, and borne before the chief officials, *e.g.* mayors. The mace belonging to the House of Commons always rests upon the table in front of the Speaker during his presence in the House. When he leaves the Chair and the House goes into committee, the mace is placed beneath the table.

Maceration. The term applied when vegetable or other substances are softened in a liquid. This process is used to separate the fibres of plants for textile purposes and in tanning. *See* LINEN MANUFACTURE, LEATHER MANUFACTURE, *etc.*

Machicolations (*Architect.*) *See* CORBEL TABLE.

Machine. An assemblage of inter-related movable parts, forming an appliance for transmitting and modifying forces and the motion produced by them. The relative motions of the parts are definitely controlled or "constrained."

—— (*Elect. Eng.*) The term machine is commonly applied by electrical engineers to dynamos, electric motors, rotary converters, boosters of all kinds, and occasionally transformers, though the latter are not, of course, machines in the mechanical sense of the word.

Machine Cut Pattern (*Foundry*). An iron pattern used for casting toothed wheels, the teeth of the pattern having been cut by a revolving cutter. Such a pattern can give a very clean casting, in which the teeth need little or no trimming.

Machine Cutters (*Eng.*) Usually applied to the revolving cutters used in milling machines, as distinguished from the tools used in planing and slotting machines.

Machine, Dynamo Electric. An obsolete expression for DYNAMOS (*q.v.*)

——, **Electrical.** A term used in physics denoting a piece of apparatus for the production of charges of electricity. They include FRICTIONAL MACHINES and INFLUENCE MACHINES, such as those of HOLTZ, VOSS, and WIMSHURST (*q.v.*)

——, **Induction** (*Elect.*) *See* INDUCTION MACHINE (HOLTZ, VOSS, and WIMSHURST MACHINES).

Machine Moulding. Many simple forms of castings, when a great number are required, are moulded by machines, which are in some cases almost automatic. Toothed wheels are very conveniently made in this way. The machines are too complex for a brief description.

Machine Paper (*Paper Manufac.*) Paper made by machinery, in contradistinction to paper made by hand. The latter is generally superior in quality.

Machine Points (*Print.*) Guide points employed on the printing machine in order to obtain accurate register.

Machine Riveting (*Eng.*) Closing rivets by the use of some form of press (often hydraulic) instead of by hammering.

Machine Shop (*Eng.*) The part of an engineering works in which the lathes and other machine tools are worked, as distinguished from the erecting and fitting shops.

Machine Tools (*Eng.*) A general term for machines used in engineering and allied work. *e.g.* PLANING, SLOTTING, SHAPING, MILLING MACHINES, *etc.*

Machining (*Eng., Carp., etc.*) A general term for processes carried out by machine tools, *e.g.* planing, shaping, and milling in metal work, and planing, grooving, and beading in woodwork.

Mackerel Sky (*Meteorol.*) A form of cloud resulting from the breaking up of cirrus cloud, composed of small roundish cloud masses.

Mackle, Mackled (*Print.*) A term implying that the type has dragged on the paper whilst the sheet was being printed, thus giving a kind of double impression.

Macle (*Min.*) A term sometimes used to signify a twin crystal of the contact type.

Maclura (*Botany*). The "bow wood" of the United States belongs to the *Moraceæ*. Its wood is used, and the leaves form food for silkworms.

Macrodiagonal (*Min.*) The longer of the two horizontal axes in the ORTHORHOMBIC SYSTEM.

Macrodome (*Min.*) A crystal form of the orthorhombic system. It is a prism whose axis is the MACRODIAGONAL (*q.v.*)

Macropinakoid (*Min.*) A two faced form of the orthorhombic system. The faces are normal to the macrodiagonal.

Madder. This is the root of ***Rubia tinctorum***, ***R. peregrina***, and ***R. mungista*** (order, ***Rubiaceæ***), a plant growing wild in many parts of Europe and Asia. The plant was at one time extensively cultivated, as the root yields a splendid red dye. It is probably the oldest vegetable red known, and has been detected in Egyptian mummy wrappings. Since the discovery of artificial alizarin, however, madder has, like many other natural dyes, practically fallen into disuse. *See* ALIZARIN *and* DYES AND DYEING.

Made Ground (*Hygiene*). A model byelaw of the Local Government Board prohibits the erection of a new building "upon any site which shall have been filled up with any material impregnated with any animal or vegetable matter, or upon which any such matter may have been deposited, unless and until such matter shall have been properly removed, by excavation or otherwise, from such site." Free exposure for years is necessary for the purification of such soil, and even then it makes an unhealthy site. Any dwelling built upon it should have an air proof basement of concrete or some impermeable material.

Maestoso (*Music*). Majestically: with dignity.

Magellanic Clouds (*Astron.*) Two cloudy oval masses of light visible in the Southern Hemisphere, called NUBECULA MAJOR AND MINOR.

Magenta. Magenta is a red dye, and was so named because it was discovered by Perkin in the year in which the Battle of Magenta was fought (1859). It is also called ANILINE RED and FUCHSINE. It is still employed to some extent as a dye, and also as a pigment in the form of a lake. *See* LAKES *and* DYES AND DYEING.

—— (*Chem.*) *See* FUCHSINE.

Maggiore (*Music*). Major, used sometimes when a piece goes from the minor key to the tonic major, *i.e.* the major key of the same note, as C minor, C major.

Magic Lantern. The colloquial term for the OPTICAL LANTERN (*q.v.*)

Magilp, Magilph (*Paint.*) A mixture of linseed oil and mastic varnish used by artists as a vehicle for pigments.

Magistral (*Chem.*) A product obtained by roasting copper pyrites (*q.v.*) in such a way as to convert the copper and iron into sulphates, and grinding the product to powder. It is used in the extraction of silver from its ores in Mexico by an amalgamation process.

Magma (*Geol.*) The molten mass from which the eruptive rocks of primary origin have subsequently consolidated.

Magnesia (*Chem.*) A common name for magnesium oxide. *See* MAGNESIUM COMPOUNDS.

Magnesia Mixture (*Chem.*) A solution used in the detection and estimation of phosphoric acid or phosphates. It is prepared as follows: 100 grams of crystallised magnesium chloride, 140 grams of ammonium chloride, and 200 cubic cm. of ammonia are made into a solution, and water added to bring the whole up to 1300 cc. The magnesium chloride can be made by precipitating a suitable quantity of the sulphate exactly with barium chloride, filtering, washing, and using the solution.

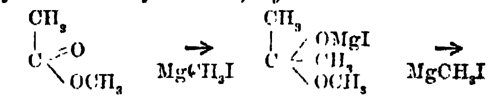
Magnesian Limestone (*Geol.*) A stratigraphical name for a magnesio-calcareous rock which forms a conspicuous horizon near the top of the Dyas, Lower New Red, or "Permian" series of rocks in the north, and especially in the north-east, of England. It was formed in the sea during a temporary return to normal geographical conditions, and in the middle of a lengthy episode during which an arid climate and continental conditions prevailed throughout what is now Western Europe. These finally changed for the better when the Rhætic rocks were formed. The Magnesian Limestone has undergone much reconstruction, and now presents, in consequence, many remarkable structural characteristics.

Magnesite (*Min.*) Magnesium Carbonate, $MgCO_3$. Magnesia = 47·6, carbon dioxide = 52·4 per cent. Rhombohedral; usually not crystallised. White, yellowish, or brown. It is used in the manufacture of Epsom Salts. From Moravia, Styria, Silesia, Norway, the United States, etc.

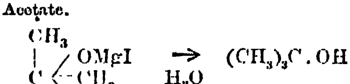
Magnesium, Mg (*Chem.*) Atomic weight, 24. A silvery white metal; melts at 633°; boils about 1100°. In dry air it is not oxidised, but in moist air becomes coated with a film of oxide. When heated in air or oxygen it burns with a very bright flame, rich in the violet and ultra violet light rays. In air the product of combustion is a mixture of the oxide and nitride of the metal. On account of the brightness of the magnesium light the metal is used in making signal lights and in pyrotechny; on account of the brightness and richness in violet and ultra violet rays the metal is used in photography, *e.g.* a good flashlight is obtained by burning a mixture of aluminium powder (12 parts), magnesium powder (13·5 parts), red phosphorus (16 parts), and saltpetre (73 parts) in a celluloid tube. The mixture must be made with a feather. On account of the great heat of formation of its oxide (143,500 cal.) magnesium is able to displace many other elements from their oxides when heated with these oxides, *e.g.* silicon, boron, carbon, etc. It is not attacked by pure water, but solutions of many salts attack it, *e.g.* solutions of potassium chloride and magnesium chloride, yielding magnesium hydroxide and hydrogen. Heated in steam it burns brightly, forming the oxide and liberating hydrogen. Dilute hydrochloric and sulphuric acids dissolve it with formation of the corresponding salt and hydrogen; dilute nitric acid also dissolves it, forming the nitrate, and evolving nitric oxide, nitrous oxide, nitrogen, and hydrogen. Magnesium also precipitates a number of metals from solutions of their salts, *e.g.* copper and iron. It occurs as sulphate in many mineral springs; in sea water; as magnesite, $MgCO_3$; dolomite, $(Mg.Ca)CO_3$; as silicate in many important minerals, *e.g.* asbestos, $(Mg.Ca)SiO_3$; meerschaum, $H_4Mg_2Si_3O_{10}$; and in the Stassfurt salt deposits as carnallite, $KCl.MgCl_2 6H_2O$; kieserite, $MgSO_4H_2O$; and other compounds. Magnesium is obtained (1) by electrolysis of fused carnallite, using a carbon anode and an iron kathode; (2) by heating together carnallite, fluorspar, and sodium to redness in a closed crucible; in this case the metal is purified by distillation.

Magnesium Compounds (*Chem.*) MAGNESIUM OXIDE, MgO: A light white powder; only melts at the temperature of the electric furnace, and on account of its refractory nature is used for lining crucibles and furnaces which are to be used at very high temperatures. Very slightly soluble in water (1 part in 172,000 parts water at 18°); yet when moistened it turns red litmus blue. Used in medicine as a purgative and an antidote in alkaloidal poisoning. It is obtained by heating the carbonate. The

Hydroxide, $Mg(OH)_2$, is a light white powder nearly insoluble in water, but readily soluble in solutions of ammonium salts. Readily gives the oxide on heating. It is obtained by adding a solution of caustic soda to a solution of a magnesium salt. Both oxide and hydroxide readily dissolve in most dilute acids. **Magnesium Nitride**, Mg_3N_2: A yellowish powder obtained by heating the metal in nitrogen or ammonia. It is readily decomposed by steam, $Mg_3N_2+6H_2O=3Mg(OH)_2+2NH_3$. The action of nitrogen on magnesium was used by Ramsay in preparing argon from the air. **Magnesium Chloride**, $MgCl_2$: A white crystalline solid, deliquescent, very soluble in water; it crystallises from a strong solution as $MgCl_2 6H_2O$, but on heating these crystals they lose hydrochloric acid and form the oxide. It forms double salts with the alkali metals, *e.g.* Carnallite, and a similar compound with ammonium chloride in place of potassium chloride. It is obtained by heating Carnallite at 175°, when most of the potassium chloride separates. On cooling, the rest of the potassium chloride separates as carnallite, and the mother liquor contains only magnesium chloride. In the laboratory the carbonate is dissolved in hydrochloric acid, ammonium chloride added to form the double salt, the solution evaporated, and the crystals heated to drive off ammonium chloride. It is used in "dressing" cotton goods. **Magnesium Sulphate**, $MgSO_4$: A white solid, decomposed about 360° into the oxide, sulphur dioxide, and oxygen. It is usually met with as the crystalline hydrate, $MgSO_4 7H_2O$; commonly called **Epsom Salts**: Fine needle shaped crystals; loses $6H_2O$ at 150°, and becomes anhydrous at 200°; very soluble in water. Epsom salts are prepared by allowing Kieserite (*see* Magnesium) to stand in contact with water till it forms $MgSO_4 7H_2O$, and this is purified by crystallisation. It can also be prepared by the action of sulphuric acid on magnesite or on dolomite; in the latter case most of the calcium sulphate remains undissolved, and the magnesium sulphate can be purified by crystallisation. A number of double salts like $K_2SO_4 MgSO_4 6H_2O$ are known. Epsom salts is used in medicine as a purgative, its action depending mainly on osmosis, water being attracted into the intestine. **Magnesium Carbonate**, $MgCO_3$: A white crystalline solid isodimorphous with calcium carbonate; that is, one form crystallises like calcspar, and the other form like arragonite. It occurs naturally as magnesite, and can be prepared by the action of a solution of the chloride on calcium carbonate or by suspending the basic carbonate in water and passing carbon dioxide through the suspension. It is very slightly soluble in water, but more soluble in water containing carbonic acid. A solution prepared by passing carbon dioxide under a pressure of 3 atmospheres into the basic carbonate is used in medicine under the name "fluid magnesia." The **Magnesia Alba** used in medicine is a basic carbonate of the composition $Mg(OH)_2 3MgCO_3$, with a variable quantity of water. It is obtained by mixing solutions of sodium carbonate and magnesium sulphate (*a*) in the cold, and then heating to boiling for the light form; (*b*) at the boiling temperature for the heavy form. Both the normal and basic carbonates are easily decomposed by heat, giving the oxide and carbon dioxide (and water from the basic carbonate). **Magnesium Ammonium Phosphate**, $MgNH_4PO_4$: Small crystals sparingly soluble in water, nearly insoluble in dilute ammonia. It is the form in which magnesium is detected and estimated. On heating, it forms **Magnesium Pyrophosphate**, $2MgNH_4PO_4 = Mg_2P_2O_7 + 2NH_3 + H_2O$. It occurs as a urinary calculus. It is prepared by adding to a solution of magnesium sulphate solutions of ammonium chloride, ammonia, and sodium phosphate in the order given. **Magnesium Sulphide**, MgS: A yellowish brown solid obtained by heating sulphur and magnesium together; it is decomposed by water: $MgS + 2H_2O = Mg(OH)_2 + H_2S$. Magnesium unites with alkyl iodides and bromides in presence of dry ether to form magnesium alkyl halogen compounds, *e.g.* $Mg\begin{matrix}\diagup CH_3\\ \diagdown I\end{matrix}$ and $Mg\begin{matrix}\diagup C_2H_5\\ \diagdown Br\end{matrix}$. These compounds are very important synthetic reagents in organic chemistry. They are decomposed by water, giving the corresponding paraffin, $Mg\begin{matrix}\diagup CH_3\\ \diagdown Br\end{matrix} + HOH = Mg\begin{matrix}\diagup OH\\ \diagdown Br\end{matrix} + CH_4$. With esters of monobasic fatty acids (except formic), acid chlorides, acid anhydrides, and ketones they yield tertiary alcohols; with the esters of formic acid they yield secondary alcohols; *e.g.*

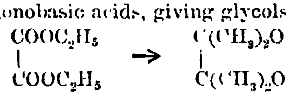


Methyl Acetate.



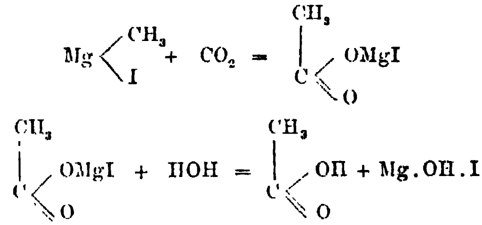
Trimethyl Carbinol.

Esters of dibasic acids react in a similar way to esters of monobasic acids, giving glycols,

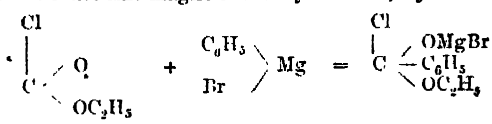


Tetramethyl Glycol (Pinacone).

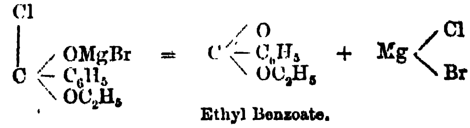
With aldehydes secondary alcohols are obtained. Acids can be synthesised by passing carbon dioxide into an ethereal solution of a magnesium alkyl haloid, and decomposing the precipitated addition product by dilute sulphuric acid at 0°—



For the action on nitriles, *see under* Ketones. Magnesium also replaces the halogen in halogen benzene derivatives, forming compounds like C_6H_5MgBr, and these react like magnesium alkyl haloids, *e.g.*



Ethyl Chlorocarbonate.



Ethyl Benzoate.

Magnesium Light (*Photo.*) An artificial light produced by burning magnesium powder or ribbon; used for photographing interiors of buildings, large groups at night, etc.

Magnet. A NATURAL MAGNET is a piece of a mineral termed MAGNETITE or MAGNETIC OXIDE OF IRON. It possesses the following properties: (1) It attracts small pieces of iron to itself when brought near them. (2) It either repels or attracts a similar magnet, according to the relative positions in which the two are placed with regard to each other. (3) If suspended so that it can turn freely, it sets itself so that two definite points within it lie along a definite direction relative to the earth; this direction is a line pointing approximately north and south. These two points in the magnet are termed its POLES; the line joining them is called the AXIS OF THE MAGNET or MAGNETIC AXIS. An ARTIFICIAL MAGNET is a piece of iron or steel which has acquired properties similar to those of the natural magnet; if it retain these properties it is termed a PERMANENT MAGNET. The MAGNETISM (that which confers on the metal the properties of a magnet) may be supposed to be concentrated at the region of the poles; the amount of such magnetism is termed the STRENGTH OF THE POLE. A UNIT POLE is one which, when placed at 1 cm. from a similar and equal pole, and separated from it by air or some other NON-MAGNETIC material (*q.v.*), repels it with a force of 1 dyne. The pole which tends to turn to the north when the magnet is suspended is termed the POSITIVE or NORTH SEEKING POLE; the other, the NEGATIVE or SOUTH SEEKING POLE. Many of the effects due to a magnet depend upon its MAGNETIC MOMENT or MOMENT OF THE MAGNET, which is the product of the strength of one pole and the length of the axis or line joining the two poles. A magnet may be formed by placing a piece of iron or steel in contact with or in the neighbourhood of another magnet, or by causing an electric current to flow through a wire coiled round the piece of iron. A piece of iron magnetised by a current in the latter way is termed an ELECTRO MAGNET. If the iron be soft, it loses the greater part of its magnetism when the magnetising influence is withdrawn; hard iron or steel retains its magnetism to a great extent, depending largely upon its hardness, and forms a permanent magnet. The main uses of permanent magnets are: (1) As the indicating part of the magnetic compass. (2) As the suspended portion of a large class of galvanometers (*q.v.*) (3) As the field magnets in magneto-electric machines; and (4) for various experimental purposes. Electro-magnets form an essential portion of most electrical appliances and machinery, *e.g.* dynamos, motors, telephones, electric bells, etc.

Magnet Core (*Elect.*) A piece (or number of pieces) of soft iron placed inside a coil or solenoid, and forming with the latter an ELECTRO MAGNET.

——, Diurnal Variation of (*Meteorol., etc.*) It is found that the magnetic needle normally oscillates through a small angle once daily over the mean magnetic meridian. This is called the DIURNAL VARIATION. The angle is greater in summer than in winter.

Magnet Filament, Solenoidal (*Elect.*) A linear magnet or arrangement of magnets having no free magnetism except at the two ends of the line; the external action of the magnet is entirely due to the magnetism at these two points. Such an arrangement is purely theoretical, and is conceived for the purpose of mathematical investigation only.

Magnet, Moment of (*Elect.*) *See* MAGNET.

——, Natural. *See* MAGNET, LODESTONE, and MAGNETITE.

——, Permanent (*Elect.*) *See* MAGNET.

——, Secular Variation of (*Meteorol.*) The progressive alteration of the angle between the magnetic and true meridians at a place. In London it is about 8·5′ annually.

Magnetic Axis (*Elect.*) The axis of a magnet is the line joining the two poles. *See also* MAGNET.

Magnetic Battery (*Elect.*) An expression, now obsolete, for a magnet built up of a number of elements, each element being a separate magnet of suitable form.

Magnetic Bearing (*Surveying, etc.*) The angle between the direction of the compass and that of a line drawn from the observer to a point under observation.

Magnetic Circuit (*Elect.*) Consider a ring of soft iron on which are wound a number of turns of insulated wire. If a current be passed through this wire a MAGNETISING FORCE is set up inside the turns (or helix), which causes a number of lines of force to pass through the iron, each line being a closed curve. The whole system constitutes a MAGNETIC CIRCUIT, having the following analogies to the electric circuit: (1) The FLUX, or total number of lines, corresponds to the electric current. (2) The amount of the flux is directly proportionate to a quantity termed the MAGNETO-MOTIVE FORCE. This is equal to $4\pi NC$, where N is the total number of turns of wire and C the current in absolute units. The magneto-motive force may be defined as the amount of work done in moving a unit magnetic pole once round the circuit, if the iron were absent. (3) The flux is inversely proportional to a quantity termed the RELUCTANCE of the circuit, or its "resistance to the magnetic lines of force." This resistance is proportional to the length of path of the lines of force through the iron, and inversely proportional to the area of the cross section and to the "conductivity for the lines of force" or PERMEABILITY. Let l be the length of the path, a the cross section of the iron, and μ the PERMEABILITY. Then the RELUCTANCE is given by the equation

$$\text{Reluctance} = \frac{l}{a\mu}$$

If a magnetic circuit be composed of different materials, the total Reluctance is the sum of the Reluctances of the separate parts; *e.g.* if there be three different materials of lengths l_1, l_2, l_3, cross section a_1, a_2, a_3, and Permeability μ_1, μ_2, μ_3, the total Reluctance is

$$\frac{l_1}{a_1\mu_1} + \frac{l_2}{a_2\mu_2} + \frac{l_3}{a_3\mu_3}$$

If a part of the path of the lines of force be in the air the Permeability of that part is unity. It is now possible to state the law of the magnetic circuit in a form analogous to the equation expressing the relation of the electric current to the electromotive force and resistance. *See* OHM'S LAW.

$$\text{Flux} = \frac{\text{Magneto-motive Force.}}{\text{Reluctance.}}$$

Magnetic Conductivity (*Elect.*) *See* PERMEABILITY.

Magnetic Control (*Elect.*) (1) The utilisation of the properties of a magnet in order to cause some freely suspended object to set itself in a definite direction, *e.g.* a small magnet is fixed rigidly to the needle of an ELECTROMETER (*q.v.*) (2) In galvanometers containing a suspended magnet the latter may be caused to set itself in a definite direction, independent of the Earth's field, by means of a permanent magnet fixed above the instrument; the directive force on the suspended magnet may also be varied in amount by raising and lowering the controlling magnet.

Magnetic Current (*Elect.*) The rate of change of MAGNETIC FLUX or number of lines of force passing through any surface.

Magnetic Curves (*Elect.*) Curves showing the direction of the lines of force from a magnet, or, more exactly, their projection upon a flat surface, such as a sheet of paper.

Magnetic Cycle (*Elect.*) A complete series of changes in the magnetic condition of a body, such that at the end of the series the body has returned to its original magnetic state.

Magnetic Declination (*Elect.*) See DECLINATION MAGNETIC.

Magnetic Deviation (*Elect.*) *See* DEVIATION, MAGNETIC.

Magnetic Dip (*Elect.*) *See* DIP.

Magnetic Elements (*Elect.*) The three quantities necessary in order to describe completely the magnetism at any given place; they are (1) DECLINATION; (2) DIP; (3) INTENSITY of the magnetic force.

Magnetic Equator (*Elect.*) A line running round the Earth, at any point of which the DIP (*q.v.*) is zero. It is, roughly, midway between the poles.

Magnetic Fatigue (*Elect.*) After iron has been subjected to a large number of changes in its magnetic state, the waste of energy due to HYSTERESIS (*q.v.*) increases. This increase is termed MAGNETIC FATIGUE.

Magnetic Field (*Elect.*) A space through which magnetic lines of force run, and in which therefore a force is exerted on any magnetic pole which may be placed there. Magnetic fields may be (1) Natural or due to the Earth's Magnetism. (2) Produced by the vicinity of magnets. (3) Due to the action of currents.

Magnetic Flux (*Elect.*) The number of magnetic lines of force (*q.v.*) passing through any given area, circuit, etc.

Magnetic Flux Density (*Elect.*) The number of lines of force passing through unit area, situated normally to the lines.

Magnetic Force. The magnetic force at any point is the mechanical force, in dynes, exerted on a UNIT MAGNETIC POLE (*see* MAGNET) placed at the point. It is also equal to the number of LINES OF FORCE crossing unit area surrounding the point. *See* LINES OF FORCE.

Magnetic Hysteresis (*Elect.*) *See* HYSTERESIS.

Magnetic Inclination (*Elect.*) *See* INCLINATION, ANGLE OF.

Magnetic Induction (*Elect.*) (1) The production of magnetic properties in soft iron, etc., when placed in a magnetic field. (2) The magnetic flux density (*q.v.*) in any material placed in a magnetic field. If H denote the strength of this field, I the intensity of magnetisation (*q.v.*) of the material, and B the magnetic induction, then $B = H + 4\pi I$.

Magnetic Lag (*Elect.*) The tendency of the induced magnetism in iron, etc., to lag behind the magnetising force to which it is due. *See also* HYSTERESIS.

Magnetic Leakage (*Elect.*) The passage of lines of force through a space in which they do not produce a useful effect; *e.g.* the passage of lines through the air from one pole piece of a dynamo to another instead of passing through the armature.

Magnetic Meridian (*Elect.*) An imaginary plane passing through the ZENITH (*q.v.*) and through the magnetic north and south points. The axis of a suspended compass needle when at rest lies in this plane.

Magnetic Moment (*Elect.*) The product of the strength of one pole of a magnet and the distance between the poles. *See also* MAGNET.

Magnetic Needle (*Elect.*) A small magnetised rod or needle of steel so suspended or pivoted that it is able to revolve freely about its middle point. The direction in which it comes to rest is that of the magnetic north and south poles, provided no disturbing magnetic influence is near enough to cause it to deviate from its normal direction.

Magnetic North (*Elect.*) The direction in which a magnetic needle points when perfectly free to turn.

Magnetic Observatory (*Elect.*) An observatory furnished with the necessary instruments for measuring the magnetic declination, inclination, intensity, etc. (*q.v.*), and for recording the variations in these quantities.

Magnetic Permeability. *See* PERMEABILITY.

Magnetic Permeance (*Elect.*) PERMEABILITY (*q.v.*)

Magnetic Poles (*Elect.*) A magnet whose length is considerable behaves as if its magnetism were situate almost entirely at two points at or near its ends; these points are termed the POLES. The condition is most nearly fulfilled by the magnets introduced by Searle, which consist of a thin steel wire having a hardened steel sphere at each end; the poles are almost exactly at the centres of these spheres. *See also* MAGNET.

Magnetic Potential (*Elect.*) The magnetic potential at a point is the work which must be done on a unit pole in order to bring it up to that point from an infinite distance, or from a point where the magnetic potential is zero. *See also* POTENTIAL.

Magnetic Reluctance (*Elect.*) A quantity which may be described as the resistance offered to the passage of lines of magnetic force through any material. It is proportional to the length of the material through which the lines run, and inversely proportional to the area of the cross section and to the Permeability (*q.v.*) *See also* MAGNETIC CIRCUIT

Magnetic Remanence (*Elect.*) *See* REMANENCE.

Magnetic Retentivity (*Elect.*) *See* RETENTIVITY.

Magnetic Sands (*Min.*) *See* ILMENITE.

Magnetic Saturation (*Elect.*) *See* SATURATION, MAGNETIC.

Magnetic Shell. A thin sheet of material, one surface of which is magnetised positively, the other negatively. It may be imagined to be built up of a great number of small magnets, each of length equal to the thickness of the sheet, placed side by side with all their like poles pointing in the same direction. The STRENGTH OF A SHELL is equal to its Magnetic Moment per unit area, or, what is the same thing, its Intensity of Magnetisation (*q.v.*) multiplied by the thickness of the shell. The chief importance of a magnetic shell (which is a purely theoretical conception) is that it produces the same magnetic field as a closed circuit of the same shape as the boundary of the shell, and which carries a current equal to the strength of the shell.

Magnetic Storms (*Meteorol.*) Abnormal variations in the earth's magnetic condition which affect the compass needle.

Magnetic Susceptibility (*Elect.*) *See* SUSCEPTIBILITY.

Magneting (*Eng.*) The separation of particles of iron from those of brass, copper, etc., when filings or borings are to be smelted.

Magnetisation, Intensity of (*Elect.*) *See* INTENSITY OF MAGNETISATION.

Magnetism. (1) The science dealing with the properties of magnets and magnetic fields. (2) The state or condition giving rise to the properties of a magnet. A magnetic field is produced whenever electricity is set in motion. By causing the current to flow in a circuit of suitable form, the properties of a magnet may be reproduced. Ampère deduced that all magnetism is due to electric currents flowing in closed circuits of small dimensions, which are present in the matter under observation. A later modification of this theory points to the movement of IONS (*q.v.*) in closed paths as being equivalent to the currents of Ampère's hypothesis.

Magnetite (*Min.*) A sesquioxide and protoxide of iron, $Fe_2O_3 . FeO$. Iron = 72·5, oxygen = 27·5 per cent. Cubic, commonly occurring in octahedra, often embedded in slaty rocks; also massive. Colour and streak black. Strongly magnetic. It is a very valuable ore of iron. Of wide distribution, but sufficiently plentiful to mine in Norway, Sweden, Lapland, and Siberia.

Magneto Electric Machine (*Elect.*) A term now applied to a small dynamo having permanent field magnets. *See also* DYNAMO.

Magnetograph (*Elect.*) A recording instrument for registering variations in the magnetic elements (*q.v.*)

Magneto Ignition (*Motor Cars, etc.*) The use of a magneto electric machine (*q.v.*) for the production of the spark required for the ignition (*q.v.*) in gas and petrol engines.

Magneto Motive Force (*Elect.*) *See* MAGNETIC CIRCUIT.

Magnification (*Optics*). The apparent increase in the size of an object when viewed through (or projected by) some optical system.

Magnifying Power (*Optics*). The ratio between the angle subtended at the eye by the image of an object viewed through an optical system, and the corresponding angle when viewed by the eye alone.

Magnitudes, Stellar (*Astron.*) Stars appear of different brightness; that is, their magnitudes are different. The brightest stars are of the first magnitude. The LIGHT RATIO (*q.v.*) between one magnitude and the next is 2·512.

Mahl Stick (*Paint.*). *See* MAULSTICK.

Mahogany. *See* WOODS.

Mail (*Armour*). A generic term for all kinds of metal armour, formed of rings, chain, or scale. Such armour was used by most Northern nations, as well as by others, from the earliest times until the fourteenth century, when it was superseded by plate armour. *See* ARMOUR.

—— *or* **Maille** (*Silk Manufac.*) A small oval shaped eyelet through which warp thread passes in figured harness. Made of glass for organzine and fine warps, and of metal for coarse spun and other warps.

Mains (*Elect. Eng.*) The insulated conductors by which the current is led from the generating dynamo to the points where it is required for lighting or power. The conductors consist of copper wires, strips, or rods. The insulating materials which surround the wires are usually covered with some protecting coating, *e.g.* a leaden sheath, and the whole main is generally laid in pipes, troughs, or other forms of conduit.

Mainspring (*Watches and Clocks*). The agent of energy in portable timepieces and small house clocks. A long strip of tempered steel coiled in the barrel, so that in its elastic endeavour to uncoil itself it drives the train of wheels.

Maintaining Power (*Watches and Clocks*). The mechanism which keeps a weight clock, or a fusee watch or clock, going during the time of winding. *See* FUSEE, GOING BARREL.

Maintenance, Cap of. *See* CAP OF MAINTENANCE.

Maize (*Botany, Foods*). Indian corn or maize, *Zea mays* (order, *Gramineæ*), is a most important cereal, not only as a food but also for the varied uses of the leaves, etc. In its nutritive value this resembles oats, containing a large quantity of fat; but its albumen, to be rendered digestible, requires careful cooking. Being deficient in gluten, maize does not make good bread. The grain is liable to be affected by a fungus, which causes in man a disease known as *pellagra*, closely resembling scurvy.

Majolica. A class of pottery the decoration of which is effected by means of white and coloured glazes. Considerable quantities of majolica are produced in England, but its home is Italy, where the productions of Lucca della Robbia and Maestro Georgio in the fifteenth and sixteenth centuries still stand pre-eminent as masterpieces in this special type of ceramics. The wares of the former master are chiefly of a yellow body, covered with an opaque white stanniferous glaze, and further ornamented by the application of coloured glazes. Those of the latter are distinguished by wonderful metallic lustres, which it is practically impossible to produce at the present day.

Major (*Music*). (1) In intervals the term given to the "greater" of those which are alike consonant or alike dissonant, *viz.* seconds, thirds, sixths, and sevenths, the smaller being termed "minor." Major intervals contain one semitone more than minor intervals. (2) Scales and concords which have a major third from the keynote and root respectively

are called "major," those having a minor third being called "minor."

Major Axis. The longest diameter of an ellipse.

Major Tone (*Sound*). The ratio between the frequencies of two notes which respectively are proportional to 9 and 8. It is termed the interval $\frac{9}{8}$ in acoustics.

Make. (1) The amount or number of separate articles produced in some given time. (2) The style or quality of article turned out under given conditions.

Make Even (*Typog.*) This term applies more generally to newspaper work, and implies that the compositor is to make his "take" or portion of copy finish off at the end of a line, unless it be a paragraph ending. This enables the various takes to be closed up without loss of time.

Make Up (*Typog.*) The term is applied (1) to the process of composing type into columns or pages; (2) to the matter when made up; (3) to the articles, etc., selected to form the number or issue of a periodical.

Making Ready (*Typog.*) The preliminary process of printing, consisting of the proper placing of the forme on the press or machine, the registering of pages, and the securing of uniform impression of the type. In printing illustrated works from wood blocks or mechanical engravings it also denotes the several processes of underlaying and overlaying (*q.v.*) required to produce the correct impression and artistic effects the varying subjects demand.

Making Up *or* **Mending Up** (*Foundry*). Repairing broken edges in a mould after the pattern is withdrawn.

Malacca Tin (*Met.*) Tin of good quality from mines in the Straits of Malacca. Also termed STRAITS TIN.

Malachite (*Min.*) A basic cupric carbonate, $2CuO.CO_2.H_2O$. Oxide of copper = 71·8, carbon dioxide = 20, water = 8·2 per cent. Also called Green Carbonate of Copper. *See* AZURITE. Monosymmetric, but rarely crystallised. Usually massive and radiating. Often mammillated. Green in colour. It is used as an ornamental stone. Very valuable as an ore of copper. It is found sparingly in Cornwall, Cumberland, Wigtonshire, Shetland, Cork, and Limerick in the British Isles; more abundantly at Chessy in France, Burra Burra in South Australia, in Siberia, the United States, etc.

Malachite Green (*Chem.*) This name is given to various salts, such as the oxalate, chloride, and zinc double chloride of tetramethyldiamidotriphenylcarbinol, $HO.C\begin{cases}C_6H_4.N(CH_3)_2\\C_6H_4.N(CH_3)_2\\C_6H_5\end{cases}$. The last named compound forms colourless shining leaflets, melting at 132°. Insoluble in water; soluble in alcohol. With acids in the cold it gives colourless solutions; but on warming, salts of the base are formed which have a splendid green colour, and are valuable dyes. On reduction it yields the leuco compound tetramethyldiamidotriphenylmethane. Malachite green is prepared as follows: Benzaldehyde (1 mol.) and dimethylaniline (2 mols.) are heated with hydrochloric acid, giving the leuco compound; the latter is carefully oxidised by lead peroxide and dilute hydrochloric acid. The lead is removed by adding sodium sulphate, and the dye precipitated by adding zinc chloride and salting out.

$$HO.\begin{cases}C_6H_4N(CH_3)_2\\C_6H_4N(CH_3)_2\\C_6H_5\end{cases} \qquad HO.C\begin{cases}C_6H_4N(CH_3)_2\\C_6H_4N(CH_3)_2\\C_6H_5\end{cases}$$

Leuco Base (Colourless). Colour Base (Colourless).

$$C\begin{cases}C_6H_4N(CH_3)_2\\=C_6H_4:N(CH_3)_2\\\qquad\quad|\\\qquad\quad Cl\\C_6H_5\end{cases}$$

Salt of Colour Base (Dye).

—— *See* DYES AND DYEING.

Male and Female (*Eng.*) Two parts forming a pair fitting into each other, such as a bolt and its nut. The former is termed a male screw or male element; the latter, the female screw.

Maleic Acid (*Chem.*), $\begin{matrix}CH.COOH\\ \|\\ CH.COOH\end{matrix}$. White rhombic prisms; melts at 130°; soluble in water and in alcohol. On distillation it yields the anhydride $\begin{matrix}CH.CO\\ \|\\ CH.CO\end{matrix}\!\!>\!O$. Reduced by sodium amalgam or hydriodic acid to succinic acid; oxidised by potassium permanganate to mesotartaric acid. Yields acetylene when a solution of its potassium salt is electrolysed. It is changed to fumaric acid on heating at 200°. Obtained from the anhydride or from malic acid (*q.v.*) directly. The anhydride easily yields the acid on solution in water. Fumaric acid yields the anhydride when heated alone or with PCl_5.

Malic Acid (*Chem.*), $\begin{matrix}CH.OH.COOH\\ |\\ CH_2.COOH\end{matrix}$. A white crystalline solid (needles); melts at 100°; deliquescent; soluble in water and alcohol. On heating it behaves as follows: Quickly distilled, maleic acid passes over and fumaric acid remains behind. Kept for a time at 140° to 150°, fumaric acid is produced. Above this temperature maleic anhydride is formed. Heated with hydriodic acid it gives succinic acid. With sulphuric acid and a phenol it forms coumarines; *e.g.* with resorcin it gives 4-oxycoumarin, $HO.C_6H_4\begin{cases}CH:CH\\ \quad |\\ O-CO\end{cases}$. Malic acid is found in many fruits, etc.; *e.g.* unripe apples, currants, cherries, in rhubarb, the tobacco plant, etc. It is obtained from mountain ash berries by neutralising the juice with milk of lime and boiling till impure calcium malate separates, and this is converted to the acid salt by addition of nitric acid, and the acid salt purified by recrystallisation. From the acid salt, malic acid is obtained by precipitating the calcium as oxalate and crystallising the solution. It can be synthesised from succinic acid (*q.v.*) thus:

$$\begin{matrix}CH_2COOH\\ |\\ CH_2COOH\end{matrix} \xrightarrow{Br_2} \begin{matrix}CHBrCOOH\\ |\\ CH_2COOH\end{matrix} \xrightarrow{AgOH} \begin{matrix}CHOHCOOH\\ |\\ CH_2COOH\end{matrix}.$$

Malic acid contains an asymmetric carbon atom, and is accordingly known in the dextrorotatory, lævorotatory, and inactive forms.

Malleability (*Phys, etc.*) The property possessed by various metals of being beaten out into sheets or otherwise changed in form by hammering, without being fractured in the process.

Malleable Cast Iron. Castings which have been deprived of some part of their carbon, thereby leaving the iron less brittle. Used instead of forgings for some small parts of machines, as malleable castings are cheaper than forgings.

Malleable Iron. Wrought iron; the term is sometimes incorrectly applied to Malleable Cast Iron.

Mallet (*Carp., etc.*) A tool consisting of a heavy head fixed on a handle like that of a hammer. Used for striking chisels, wooden objects which would be injured if struck by a hammer, etc. The head may be a block of wood, an iron casing with a wooden core, which projects at each end of the casing so as to form a striking face, or occasionally some other material, *e.g.* raw hide, which is cut into a strip and rolled up to form a cylinder. A raw hide mallet is very useful for many kinds of work which would be injured by a blow from a wooden mallet.

Malm Rubbers. Soft bricks used for the voussoirs of gauged arches. *See also* BRICKS.

Malonic Acid (*Chem.*), $\begin{matrix}COOH\\|\\CH_2\\|\\COOH\end{matrix}$

White crystalline solid; melts at 32°; readily soluble in water and in alcohol. On heating above its melting point, it decomposes into carbon dioxide and acetic acid, $CH_2\begin{matrix}\diagup COOH\\ \diagdown COOH\end{matrix} = \begin{matrix}CH_3\\|\\COOH\end{matrix} + CO_2.$

It is obtained from monochloracetic acid by evaporating a solution of its potassium salt with potassium cyanide, and hydrolysing the potassium cyanacetate so produced with strong hydrochloric acid: from the product the acid is extracted by ether.

$$\begin{matrix}CH_2Cl\\|\\COOK\end{matrix} \xrightarrow{KCN} \begin{matrix}CH_2CN\\|\\COOK\end{matrix} \xrightarrow{HClAq} \begin{matrix}CH_2COOH\\|\\COOH\end{matrix}$$

The ethyl ester is far more important than the acid itself, on account of the large number of syntheses which can be performed with it. This ester, which boils at 195°, is made from the potassium cyanacetate obtained as above, by acting on it with absolute alcohol and dry hydrogen chloride, pouring into ice-cold water, extracting with ether, drying, and fractionally distilling the dry ether extract. In this ester one of the methylene hydrogens is replaceable by sodium (both hydrogens can be replaced by sodium ethoxide), and the sodium malonic ester readily reacts with halogen derivatives, as follows, *e.g.*

$$\begin{matrix}COOC_2H_5\\|\\CH_2\\ \\COOC_2H_5\end{matrix} \quad Na \quad \begin{matrix}COOC_2H_5\\|\\CHNa\\ \\COOC_2H_5\end{matrix} \quad \xrightarrow{C_2H_5I} \quad \begin{matrix}COOC_2H_5\\|\\CHC_2H_5\\|\\COOC_2H_5\end{matrix}$$

The hydrogen atom of the ethyl malonic ester so obtained can be replaced in a perfectly similar manner. When these alkyl and other malonic ester derivatives are hydrolysed, the resulting dibasic acid readily splits off carbon dioxide on heating, *e.g.*

$$\begin{matrix}COOH\\|\\CHC_2H_5\\|\\COOH\end{matrix} = CO_2 + \begin{matrix}CH_2 . C_2H_5\\|\\COOH\end{matrix}$$

Ethylmalonic Acid. **Butyric Acid.**

$$\begin{matrix}COOH\\|\\C(CH_3)_2\\|\\COOH\end{matrix} = CO_2 + \begin{matrix}CH(CH_3)_2\\|\\COOH\end{matrix}$$

Isobutyric Acid.

Other important examples of the use of ethyl malonate as a synthetic agent are the following: (1) Disodium ethyl malonate with ethylene dibromide yields ethyl trimethylene dicarboxylate.

$$\begin{matrix}CH_2Br\\|\\CH_2Br\end{matrix} + Na_2C(COOC_2H_5)_2 = 2NaBr + \begin{matrix}CH_2\\|\\CH_2\end{matrix}\!\!>C(COOC_2H_5)_2$$

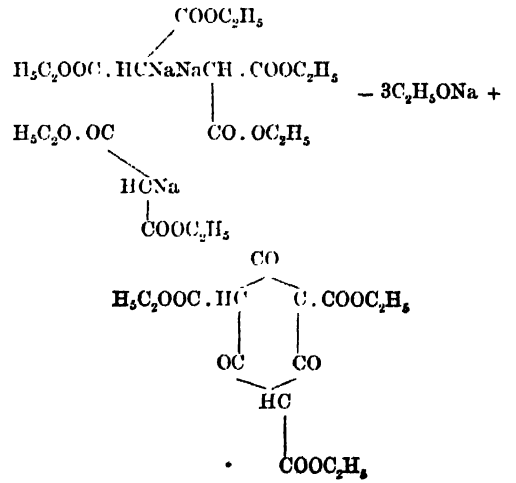
(2) Sodium ethyl malonate with ethyl monobromacetate yields succinic acid.

$$\begin{matrix}COOC_2H_5\\|\\CHNa\\|\\COOC_2H_5\end{matrix} + BrCH_2.COOC_2H_5 = \begin{matrix}COOC_2H_5\\|\\CH.CH_2.COOC_2H_5\\|\\COOC_2H_5\end{matrix} + NaBr.$$

$$\begin{matrix}COOC_2H_5\\|\\CHCH_2COOC_2H_5\\|\\COOC_2H_5\end{matrix} + 3H_2O = \begin{matrix}COOH\\|\\CHCH_2COOH\\|\\COOH\end{matrix} + 3C_2H_5OH$$

$$\begin{matrix}COOH\\|\\CH.CH_2COOH\\|\\COOH\end{matrix} = CO_2 + \begin{matrix}CH_2 . CH_2COOH\\|\\COOH\end{matrix}$$

In this kind of reaction the complexity of the halogen fatty ester, and also of any alkyl group previously introduced into the ethyl malonate, influences the result by "space filling." Thus the reaction occurs readily between sodium ethyl malonate and ethyl monobromacetate, less readily when ethyl α-brompropionate is used, and still less readily when ethyl α-bromisobutyrate is used. With ethyl alkylsodiomalonate and ethyl monobromacetate the ease of the reaction depends on the alkyl group, being easiest with methyl, less easy with ethyl, and not occurring at all with the isopropyl group. (3) Ethyl sodiomalonate, when heated to 120° to 145°, undergoes condensation to ethyl phloroglucin tricarboxylate:



Malt. On germination of the barley grain, *Hordeum vulgare* (order, *Gramineæ*), under suitable conditions of warmth and moisture, the ferment DIASTASE is formed, which changes the starch of the grain into grape sugar and dextrin. The result is malt.

Maltase *or* **Glucase** (*Chem.*) An enzyme (*q.v.*) having the property of hydrolysing the sugar maltose to glucose; it can also to some extent reproduce maltose from glucose. The enzyme is widely spread in both the animal and vegetable kingdoms, *e.g.* in the intestine, pancreas, liver, the blood, and in yeast and the moulds *Aspergilla niger* and *Penicillium glaucum*, in maize, etc.; but the enzyme from all these is probably not quite the same, as yeast maltose hydrolyses α-methyl glucoside, while animal maltase does not. Maltase has the property of resolving amygdalin into a simpler glucoside (the glucoside of benzaldehydecyanhydrin) and one molecule of glucose. Its optimum temperature is 40° to 45°. The enzyme is prepared from a watery extract of maize or from yeast.

Maltose (*Chem.*), $C_{12}H_{22}O_{11} \cdot H_2O$. A white crystalline solid; soluble in water; sparingly soluble in alcohol; dextrorotatory: the fresh solution, + 118·8°; on standing, + 136·8°. Reduces Fehling's solution and ammoniacal silver; gives an osazone (*q.v.*) with phenylhydrazine. Carefully oxidised by bromine water, it yields a monobasic acid, maltobionic acid: oxidised by nitric acid, it gives the dibasic saccharic acid. The enzyme maltase (*q.v.*) hydrolyses it to glucose; so does dilute sulphuric acid on heating. It is fermentable by yeast to alcohol and carbon dioxide. Maltose is prepared from starch by the action of malt; dilute starch paste is treated with malt (or malt extract) at 60° for an hour, boiled and filtered, concentrated, and the syrup extracted with alcohol. After some days the alcoholic solution deposits crystals of maltose.

Mamelières (*Armour*). Circular ornamental plates or bosses fastened on the surcoat of a knight over the breasts. Attached to the mamelières were chains, one of which secured the helmet, the other the sword. They were used from *temp.* Edward I. to Henry V.

Mammals *or* **Mammalia** (*Zool.*) The highest class of animals. The chief characters distinguishing mammals from lower classes are: (1) the close and prolonged connection between the mother and unborn young; (2) the nutrition of the offspring by the mother's milk. There is a small sub-class, however, the MONOTREMATA, including the Duckmole (*Ornithorhyncus*) and certain other animals, which, though possessing mammalian characters, are oviparous, *i.e.* lay eggs. A second sub-class include the MARSUPIALS (kangaroo, etc.); in this the young are born prematurely, and transferred to an external pouch. All other mammals are classed as PLACENTAL MAMMALS, from the presence of the Placenta, the structure uniting the young, before birth, to the mother.

Mancando (*Music*). Weakening the tone.

Manche *or* **Maunche** (*Her.*) A sleeve with long hanging ends, as worn by ladies about the time of Henry I. Used as a charge, but in very conventional form.

Mandelic Acid (*Chem.*) Phenylglycollic acid, $C_6H_5 \cdot {}^*CHOH \cdot COOH$. Contains an asymmetric carbon atom,* and is accordingly known in the dextrorotatory, lævorotatory, and inactive forms. It is a white crystalline solid; the active forms both melt at 133°, and the inactive form melts at 118°; it is soluble in water, alcohol, ether; it is oxidised by dilute nitric acid to benzoylformic acid, then to benzoic acid:

$$\underset{\displaystyle |\atop \displaystyle COOH}{C_6H_5CHOH} \rightarrow \underset{\displaystyle |\atop \displaystyle COOH}{C_6H_5CO} \rightarrow C_6H_5COOH$$

It is reduced by hydriodic acid to phenylacetic acid. The other halogen acids give phenylhalogen acetic acids. It is obtained from amygdalin by warming with hydrochloric acid, and synthetically by acting on benzaldehyde with hydrocyanic acid and hydrolysing the product:

$$C_6H_5CHO \xrightarrow[HCN]{} C_6H_5 \cdot C \begin{cases} H \\ OH \\ CN \end{cases} \xrightarrow[2H_2O]{} C_6H_5C \begin{cases} H \\ OH \\ COOH \end{cases}$$

The active forms can be obtained from the inactive form by making the cinchonine salt of the latter and crystallising. The *d*-mandelic acid salt is the less soluble. Also *Penicillium glaucum* destroys the lævo form, and leaves the dextro form, when it is allowed to grow in inactive ammonium mandelate. When the inactive acid is made into the lævo menthol ester the dextro acid esterifies quicker than the lævo acid, and in this way a separation can be effected.

Mandevile *or* **Mandilion** (*Cost.*) A jerkin or loose cloak, generally without sleeves, worn during the sixteenth and seventeenth centuries.

Mandoline (*Music.*) *See* MUSICAL INSTRUMENTS (STRINGED, II.)

Mandrel *or* **Mandril** (*Eng.*) (1) A general term for a cylindrical object on which work can be mounted for operation in the lathe or elsewhere. (2) The spindle of the headstock of a lathe (*q.v.*)

Maned (*Her.*) When the mane of an animal differs in tincture from the body, it is blazoned maned or, or gu., etc.

Manganates (*Chem.*) *See* MANGANESE COMPOUNDS.

Manganese, Mn (*Chem.*) Atomic weight, 55. A lustrous reddish grey metal; melts in hydrogen at 1240°; stable in air only when pure; when finely divided it attacks water on heating. Easily attacked by acids, giving a manganous salt and liberating hydrogen; even acetic acid attacks it. It precipitates most metals from solutions of their salts, especially the sulphates, on warming. It is not magnetic. For its alloy with iron *see* IRON. Manganese bronze, used in making ships' propellers, is an alloy of copper with ferromanganese. Its principal naturally occurring forms are the dioxide, called PYROLUSITE, MnO_2; BRAUNITE, Mn_2O_3; HAUSMANNITE, Mn_3O_4; MANGANESE SPAR (RHODOCROSITE), $MnCO_3$. The metal may be best obtained by the Goldschmidt process (*q.v.*); also by electrolysis of a saturated solution of manganous chloride, using a kathode of pure mercury and an anode of carbon contained in a porous pot; the product is washed, dried, pressed, and gently heated in a stream of pure and dry hydrogen.

Manganese Bronze (*Met.*) An alloy containing copper, tin, and some FERROMANGANESE (*q.v.*) It forms a very durable alloy, which resists sea water, and is used for propellers of ships.

Manganese Compounds (*Chem.*) Manganese forms three classes of compounds, *viz.* MANGANOUS SALTS, derived from the oxide MnO; MANGANIC SALTS,

derived from the oxide Mn_2O_3; and salts in which manganese occurs in the acid radical, *e.g.* MANGANITES, $R^1_2MnO_3$; MANGANATES, $R^1_2MnO_4$; and PERMANGANATES, R^1MnO_4. MANGANOUS OXIDE, MnO: A green powder; heated in air it gives Mn_3O_4; with acids it yields the manganous salts; obtained by heating any of the higher oxides in a current of hydrogen. If the dioxide is used and the hydrogen is mixed with a little hydrogen chloride, the product is crystalline. Manganous hydroxide, $Mn(OH)_2$: A white solid which rapidly oxidises on exposure to air, forming ultimately Mn_2O_3. It is obtained by mixing air free solutions of manganous chloride and caustic potash in absence of air. MANGANOUS CHLORIDE, $MnCl_2$: A rose coloured deliquescent crystalline solid; vapour density at 1200°—1500° corresponds to formula Mn_2Cl_4; very soluble in water and in alcohol; it gives a green flame in the Bunsen burner. From its aqueous solution it crystallises with $4H_2O$. Obtained by heating the carbonate in a stream of dry hydrogen chloride. From ordinary manganese dioxide (which contains iron) it may be prepared by boiling with hydrochloric acid, precipitating a fraction of the solution by sodium carbonate, filtering and washing the precipitate, and putting it into the remainder of the solution: the manganese carbonate precipitates all the iron as hydroxide; the liquid is now filtered and crystallised. MANGANOUS SULPHATE, $MnSO_4$: A faint rose coloured solid obtained by heating $MnSO_45H_2O$ at 280°; decomposed at a red heat to Mn_3O_4, sulphur dioxide and oxygen. The salt is known crystallised with from 1 to 7 molecules water of crystallisation. Its solution crystallised below 6° gives $MnSO_47H_2O$; isomorphous with $FeSO_47H_2O$; crystallised between 7° and 20° it gives $MnSO_45H_2O$; isomorphous with copper sulphate, $CuSO_45H_2O$, Double salts with the alkali sulphate are known, *e.g.* $K_2SO_4MnSO_46H_2O$ and $K_2SO_4MnSO_44H_2O$. To obtain the salt, manganese dioxide is heated with strong sulphuric acid, water added, filtered, a part precipitated with sodium carbonate, and so on just as under Manganous Chloride. MANGANOUS BORATE, $MnH_4(BO_3)_2$: Is a white powder when freshly precipitated, a brownish powder when dried at 100°; obtained by mixing solutions of manganous sulphate and borax. When added to oils which have the property of absorbing oxygen from the air and slowly forming resins, it greatly accelerates this reaction; hence it is used in the preparation of "drying" oils, etc. TRIMANGANIC TETROXIDE, Mn_3O_4: A reddish brown solid; not changed by heating in air; reduced to MnO by heating in hydrogen, carbon monoxide, or with carbon. Heated with sulphuric acid it gives a mixture of manganous and manganic sulphates; with hydrochloric acid it gives manganous chloride and chlorine; with nitric acid it gives manganous nitrate and manganese dioxide: $Mn_3O_4 + 4HNO_3 = 2Mn(NO_3)_2 + MnO_2 + 2H_2O$. It is obtained by heating any of the other oxides to a high temperature in air, the lower oxide taking up oxygen and the higher oxides losing oxygen; also by heating strongly a mixture of potassium and manganese sulphates: this gives crystals. MANGANIC OXIDE, Mn_2O_3: The natural form, braunite (*q.v.*), forms brownish black crystals; the artificial form is a black powder; strongly heated, it gives Mn_3O_4. With concentrated sulphuric or hydrochloric acids it forms the corresponding manganic salts—sulphate and chloride; but these readily decompose on warming into manganous salts and oxygen and chlorine respectively. It is obtained by allowing manganic sulphate to deliquesce in the air, when it gives the hydrated oxide $Mn_2O_3H_2O$, and this on washing, drying, and gently heating gives the anhydrous oxide; also by heating manganese dioxide in oxygen at 230°. MANGANIC FLOURIDE, MnF_3: A crystalline solid obtained by the action of fluorine on manganous iodide. When heated it gives manganous fluoride and fluorine, so that if this reaction is performed in glass vessels, the glass is violently attacked. MANGANIC CHLORIDE, $MnCl_3$, is only known in solution in cold concentrated hydrochloric acid. MANGANIC SULPHATE, $Mn_2(SO_4)_3$: A dark green solid; decomposes on heating at 180°; deliquescent; easily hydrolysed by water:

$$Mn_2(SO_4)_3 + 4H_2O = (Mn_2O_3.H_2O) + 3H_2SO_4$$

It is obtained by heating a paste of precipitated manganese dioxide and sulphuric acid at 110°, till oxygen is given off; then at 135° to 140°, till it liquefies. This liquid deposits the sulphate which is freed from sulphuric acid by allowing to stand on a porous plate, then washing with concentrated nitric acid, and heating at 150° till the latter is removed. The MANGANESE ALUMS are formed by the union of this sulphate with the alkali sulphates, *e.g.*

$$K_2SO_4 . Mn_2(SO_4)_3 24H_2O$$

MANGANESE DIOXIDE, MnO_2, *also called* Black Oxide of Manganese and Pyrolusite: A black crystalline solid or black finely divided powder. On heating, forms first Mn_2O_3, then Mn_3O_4. It conducts a current of electricity, and on this account, as well as on account of its power to give up oxygen, it is used in the Leclanché cell (*q.v.*) On heating in hydrogen or carbon monoxide, or with carbon, it is reduced to manganous oxide. Heated with sulphuric acid it gives manganous sulphate and oxygen; with hydrochloric acid, manganous chloride and chlorine. It acts as a catalytic agent in the decomposition of hydrogen peroxide and potassium chlorate. It has distinctly acid properties, combining with bases to form manganites. The hydrated oxide formed by precipitation methods is soluble in water, and the solution is acid; also, when precipitation occurs in presence of a base, the precipitate contains some of the base, *i.e.* it contains a manganite. When heated with alkalis manganese dioxide gives manganates (see below). It is prepared by dissolving manganous carbonate (precipitate the chloride with sodium carbonate, filter, and wash) in dilute nitric acid, evaporating to a syrup and heating at 160° to 165° for some hours; washing product with boiling water; drying over sulphuric acid; and finally heating at 180° to 200°. It is formed when manganous sulphate is precipitated by excess of potassium permanganate in presence of acid (nitric); but the precipitate contains potassium—in fact, pure manganese dioxide cannot be prepared by precipitation methods. Besides its use in the Leclanché cell, manganese dioxide is used in colouring pottery brown or violet, in correcting the colour of glass which contains iron, and would be coloured by this, and in the preparation of all other manganese compounds. MANGANESE TRIOXIDE, MnO_3: A reddish, amorphous, deliquescent solid; slowly decomposes at ordinary temperatures; with water it first gives manganic acid, H_2MnO_4, and this decomposes into permanganic acid and manganese dioxide; with alkalis it forms manganates. To obtain it, dry sodium carbonate is placed in a flask standing in cold water; from a tap funnel a solution of potassium permanganate in concentrated sulphuric acid (6 grams in 100 c.c.) is dropped slowly on to the carbonate; the oxide is given off as a pink cloud and condensed in a U-tube filled with broken glass and immersed in ice and salt. The MANGANATES: Salts

of the very unstable manganic acid H_2MnO_4; they are green in colour, and isomorphous with the sulphates; they are all decomposed by acids. Solutions of manganates are only stable in presence of excess of alkali. Potassium manganate may be taken to illustrate their preparation and properties; it is prepared by heating manganese dioxide with caustic potash. If the reaction is performed out of air and in the absence of any oxidising agent, one part of the dioxide is used in oxidising the other part:

$$3MnO_2 + 2KOH = K_2MnO_4 + H_2O + Mn_2O_3$$

$$\left[\begin{array}{c} 2MnO_2 = Mn_2O_3 + O \\ MnO_2 + K_2O.H_2O + O = K_2O.MnO_3 + H_2O \end{array}\right]$$

In presence of an oxidising agent such as potassium chlorate we have:

$$3MnO_2 + 6KOH + KClO_3 = 3K_2MnO_4 + 3H_2O + KCl$$

Potassium manganate is decomposed by water and acids, one part of the manganate being oxidised to permanganate at the expense of the other part:

$$3K_2MnO_4 + 2H_2O = 2KMnO_4 + MnO_2 + 4KOH$$

$$\left[\begin{array}{c} K_2O.MnO_3 = K_2O + MnO_3 = K_2O + MnO_2 + O \\ 2K_2O.MnO_3 + O = K_2O.Mn_2O_7 + K_2O = \\ 2KMnO_4 + K_2O \\ 2K_2O + 2H_2O = 4KOH \end{array}\right]$$

$$5K_2MnO_4 + 4CO_2 + nH_2O = 4KMnO_4 + MnCO_3 + 3K_2CO_3 + nH_2O$$

$$\left[\begin{array}{c} K_2O.MnO_3 + 2CO_2 = K_2CO_3 + MnCO_3 + 2O \\ 4K_2O.MnO_3 + 2O = 2K_2OMn_2O_7 + 2K_2O = \\ 4KMnO_4 + 2K_2O \\ 2K_2O + 2CO_2 = 2K_2CO_3 \end{array}\right]$$

MANGANESE HEPTOXIDE, Mn_2O_7: A dark reddish brown oil; deliquescent; slowly decomposes on standing in air; with water it forms a solution of permanganic acid, $HMnO_4$. It is obtained by dissolving potassium permanganate in concentrated sulphuric acid, which is kept cold by being immersed in a freezing mixture; on cautiously adding water to the green solution, the heptoxide separates. THE PERMANGANATES: The most important of these is potassium permanganate, $KMnO_4$; it forms very dark red prisms with a bluish lustre; moderately soluble in water; on heating it loses oxygen and forms the manganate; it is isomorphous with potassium perchlorate. Its aqueous solution is a powerful oxidising agent; *e.g.* when boiled with toluene it oxidises it to benzoic acid. On account of this oxidising action it is used in medicine as a disinfectant. Its solution with addition of caustic potash is also used as an oxidising agent; in this case the manganate is first formed and then reduced to hydrated manganese dioxide. Such a solution is used, for example, in water analysis in estimating "albuminoid ammonia." Baeyer used the permanganate in presence of sodium carbonate to distinguish between saturated and unsaturated acids. He gives the following table:

INSTANTANEOUSLY OXIDISED.	NOT INSTANTANEOUSLY OXIDISED.
Open Forms.	
Formic acid. The unsaturated acids, *e.g.* fumaric, citraconic, etc., bromacrylic, propiolic, cinnamic, oleic. The last four not quite so rapidly as the others.	Saturated fatty acids except formic, *e.g.* acetic, oxalic, malonic, etc. It is remarkable that the ester of malonic acid is instantaneously oxidised, behaving like ethyl acetoacetate.
Ring Forms.	
The unsaturated hydrogen addition products of the benzenecarboxylic acids, *e.g.* diand tetrahydroterephthalic acids.	Benzene and naphthalenecarboxylic acids. Benzene carboxylic acids saturated with hydrogen, *e.g.* hexahydroterephthalic acid.

Potassium permanganate solution acidified with an excess of sulphuric acid acts as a very powerful oxidising agent:

$$2KMnO_4 + 4H_2SO_4 = 2KHSO_4 + 2MnSO_4 + 3H_2O + 5O$$

On account of this reaction a solution of permanganate of known strength is much used in volumetric analysis. Examples: It oxidises ferrous sulphate to ferric sulphate. We have $2FeSO_4 + H_2SO_4 + O = Fe_2(SO_4)_3 + H_2O$; therefore $2KMnO_4$ gives 5O, which oxidises $10FeSO_4$; it oxidises oxalic acid to carbon dioxide and water. We have

$$C_2H_2O_4 + O = 2CO_2 + H_2O;$$

therefore $2KMnO_4$ gives 5O, which oxidises $5C_2H_2O_4$. Hydrochloric acid heated with potassium permanganate readily gives chlorine:

$$2KMnO_4 + 16HCl = 2KCl + 2MnCl_2 + 8H_2O + 5Cl_2$$

For its action on manganous salts see **Manganese Dioxide**; it also oxidises sodium thiosulphate to sodium sulphate. When hydrogen or carbon monoxide is passed through an acidified solution of potassium permanganate, oxygen is evolved. The preparation of this important salt is as follows: caustic potash and potassium chlorate are melted together in an iron crucible, and manganese dioxide added gradually with constant stirring. The green mass obtained on cooling is extracted with water, and a rapid stream of carbon dioxide passed through the liquid, which is then filtered through glass wool, asbestos, or guncotton, and concentrated to crystallisation point. CONDY'S FLUID is a solution of a crude sodium permanganate, obtained by using sodium carbonate in place of caustic potash, and oxidising by air instead of potassium chlorate. The sodium salt is more soluble than the potassium salt, but its reactions are quite similar.

Manganese Spar (*Min.*) A synonym for RHODONITE (*q.v.*)

Manganite (*Min.*) Hydrous sesquioxide of manganese, $Mn_2O_3.H_2O$. Manganese = 62·5, oxygen = 27·5, water = 10 per cent. Orthorhombic, in long striated crystals. Iron black. Often associated with Barytes. It occurs sparingly in Cornwall and Aberdeenshire; more plentifully at Ihlefeld in the Harz; also from several localities in North America.

Manhole (*Eng., etc.*) An opening into a boiler, tank, etc., through which a workman can enter to inspect the interior or to effect repairs. It is closed by a closely fitting watertight door held in position by bolts, and usually so arranged that the internal pressure tends to force it more closely against its seating.

—— (*Hygiene, Build.*) A manhole or intercepting chamber is generally constructed on a foundation of brickwork lined with cement. The main drain should run across the chamber in an open channel formed of half or threequarter channel pipes. Branch drains, in the form of suitably curved channel pipes, should be made to discharge over the main channel, which itself discharges into a syphon trap. This trap should be provided with a raking arm, one end of which opens into the manhole. The chamber should be closed with an airtight cover, and the fresh air admitted by a 6 in. pipe, the manhole end being opposite the entrance of the drain, and the open air end covered by an iron grating and provided with a mica flap. An INSPECTION CHAMBER (*q.v.*) should, if possible, be provided at each point where a change in the direction of the drain is effected.

Manihot (*Botany*). A South American plant of the order *Euphorbiaceæ*. From the tuberous roots are prepared CASSAVA MEAL or BRAZILIAN ARROWROOT and TAPIOCA. One species (*M. glaziovii*) yields CEARA RUBBER.

Manilla Hemp. A native of the Philippine Islands, *Musa textilis* (order, *Musaceæ*), producing valuable fibre for ropes. The fibres are obtained from the stem, previous to flowering.

Manilla Rope. Rope made from the fibres of *Musa hoglodyarum*, a plant growing in Manilla.

Manioc. A synonym for MANIHOT (*q.v.*)

Maniple *or* **Fanon** (*Archæol*). Originally a piece of linen, shaped like a scarf, worn by priests across the left hand or arm, and used by the sacrificing priest perhaps as a handkerchief. On the Bayeux tapestry a maniple is seen in the left hand of Stigand, Archbishop of Canterbury. Subsequently the maniple was richly ornamented.

Manley Stone. *See* BUILDING STONES.

Manna. A saccharine substance used in medicine and obtained as an exudation from the incised stem of a species of ash, *Fraxinus ornus* (order, *Oleaceæ*).

Mannitol *or* **Mannite** (*Chem.*), $CH_2OH.(CHOH)_4.CH_2OH$. A white crystalline solid; sweet taste; melts at 166°; dextrorotatory in solution in presence of borax; soluble in water, sparingly soluble in alcohol. Hydriodic acid reduces it to secondary hexyl iodide, $C_6H_{13}I$. On cautious oxidation with nitric acid it yields the sugar mannose, which is the aldehyde of mannitol; stronger oxidation converts it into saccharic acid. A mixture of concentrated nitric and sulphuric acids gives the hexanitrate. Acetic anhydride gives the hexa-acetate. It occurs in manna (the evaporated sap of species of ash), celery, common syringa, in a common fungus (*Agaricus integer*), and it is obtained from manna by boiling with dilute alcohol, allowing to crystallise, and then purifying the crystals by recrystallisation. It is also obtained by reduction of mannose, lævulose, and mannonic acid. The lævo and inactive forms are known.

Mannonic Acid (*Chem.*), $CH_2OH.(CHOH)_4COOH. = C_6H_{12}O_7$. Only known in the form of its salts. When liberated from its salts it forms the Lactone (*see* LACTONES) $C_6H_{10}O_6$: a white crystalline solid (prisms); melts about 150°; soluble in water; it is known in the dextro, lævo, and inactive forms. The inactive acid can be resolved by making its strychnine salt and crystallising from alcohol when the lævo salt separates first. When *d*-mannonic acid is heated with quinoline and a little water at 140°, it is partly converted into *d*-gluconic acid, the unchanged *d*-mannonic acid being separated by means of its brucine salt. Mannonic acid yields mannose on reduction. It is prepared by oxidation of mannose (*q.v.*), or from gluconic acid by heating with quinoline (*see above*):

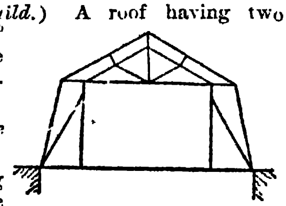
$$\text{Mannonic acid} \underset{\left(\begin{smallmatrix}\text{Heated with}\\ \text{quinoline}\end{smallmatrix}\right)}{\rightleftarrows} \text{Gluconic acid.}$$

Mannose (*Chem.*), $CH_2OH.(CHOH)_4CHO$. Colourless solid; melts at 136°; soluble in water. It is known in the dextro, lævo, and inactive forms. The inactive form can be made to yield the lævo form by fermentation with yeast, when the dextro form is first decomposed, the lævo form remaining. It is sweet; reduces Fehling's solution; yields the same osazone as glucose with phenylhydrazine. On reduction it yields mannitol, and on careful oxidation with bromine it yields mannonic acid. It is obtained from the reserve cellulose (seminine; hence this sugar is sometimes called seminose) of plant seeds by hydrolysis with a dilute acid; also by oxidation of mannitol (*q.v.*) *See also* DEXTROSE *and* SUGARS.

Manometer (*Phys.*) An instrument for measuring fluid pressure; the simplest form consists of a U-tube, one limb being open, the other connected to the vessel containing the fluid whose pressure is to be measured. A suitable liquid (*e.g.* mercury) is placed in the bend of the tube. The difference in level of the liquid in the two limbs enables the required pressure to be calculated. A simple form of AIR MANOMETER is formed by sealing up the free end of a similar U-tube, so as to enclose a convenient volume of air above the mercury in the sealed limb. The pressure is calculated from the amount by which this air is compressed, *i.e.* from Boyle's Law, making allowance for the difference in level of the mercury in the two limbs.

Manometric Flame (*Phys.*) A gas flame used for indicating small variations of gaseous pressure, as in experiments on vibrating columns of air. The changes of pressure are communicated to the gas supplying the flame by means of a flexible diaphragm; the space on one side of this communicates with the gas supply, and that on the other with the air which is in vibration. The variations of pressure cause changes in the size of the flame; these changes are observed by means of a rotating mirror, as they are too rapid to be detected by the unaided eye.

Mansard Roof (*Build.*) A roof having two pitches, generally 60° and 30°, to allow space for a room in the roof. *See also* ROOFS.



MANSARD ROOF.

Mansfield Stone. *See* BUILDING STONES.

Mantle (*Her.*) A long robe worn in the middle ages over the armour, and still used as part of the insignia of knightly orders.

——, **Incandescent.** A cap or cover composed of a meshed fabric containing oxides of certain rare earths; when heated by being placed over a non-luminous flame it becomes incandescent, emitting a brilliant light, somewhat rich in violet rays. The best known form is the WELSBACH MANTLE (*q.v.*)

Mantling (*Her.*) *See* LAMBREQUIN.

Manual (*Music*). The keyboard played by the hands. *See* ORGAN.

Manubrium (*Zool.*) A process (*q.v.*) of the sternum and of the hammerbone or malleus in the ear.

Maple. *See* WOODS.

Map Varnish. The prime requisites for a map varnish are transparency and elasticity, so that the varnish does not hide details, and will not crack if the map is rolled up, nor peel off with atmospheric changes. Any nearly colourless gum may be dissolved in a colourless solvent to prepare these varnishes. Sandarach or mastic, with spirit of wine and Venice turpentine as solvents, form the usual

ingredients. The Venice turpentine increases the elasticity. An excellent recipe is: 72 oz. of finest mastic, 46 of oil of turpentine, 10 of Venice turpentine, 3 of camphor, and 200 of strong spirit of wine (96 per cent.)

Maraschino. A liqueur made from cherry kernels that have been infused in spirit and afterwards distilled.

Marble (*Build.*) *See* BUILDING STONES.

—— (*Geol.*) A term often used to denote any kind of rock other than granite or freestone, which is suitable for decorative building purposes. Marble is, however, strictly speaking, a limestone of pleasing colour and pattern, which takes and retains a good polish. Most of the marbles, and especially those with a saccharoidal structure, were originally limestones of ordinary character, which have undergone recrystallisation. In the process of this reconstruction the various impurities present in the rock have also undergone rearrangement, and thus given rise to some of the varied patterns seen in marble.

Marbled Paper, Marbled Edges (*Bind.*) Marbled paper, *i.e.* paper coloured and veined in imitation of marble, is often used to form the end papers of books. It is also used for the covers of certain styles of half bound books. The edges of books when marbled should match the end papers.

Marble, Imitation. *See* MAREZZO *and* SCAGLIOLA.

——, **Statuary.** The marble chiefly employed for sculpture is of a saccharoidal texture, *i.e.* it resembles in structure loaf sugar. The marbles used most extensively by the ancient Greeks were (1) Parian: a finely grained, durable stone from which some of their finest figures, including the famous Venus de Medici, were formed. (2) Pentelic: a coarser grained stone than Parian; used entirely in the construction of the Parthenon. In modern times the best known and most extensively employed is Carrara, a serviceable and beautiful medium, when pure; but it is not infrequently blemished by black or grey veinings.

Marcasite (*Min.*) A sulphide of iron, FeS_2. Sulphur = 53, iron = 47 per cent. Orthorhombic; often twinned. It is a less stable compound than Iron Pyrites, and is rather paler in colour usually, being a pale brassy colour. It is a much less plentiful mineral than pyrites. Formerly used for ornamental purposes. Of wide distribution, often in altered limestone; also in the chalk.

Marcatissimo (*Music*). Very marked: greatly accented.

Marcato (*Music*). Marked: accented.

Marchioness (*Build.*) A roofing slate measuring 22 by 11 in.

Mares' Grease. A lubricant from the fat of horses slaughtered for hides, etc., in South America. *See* LUBRICANTS.

Marezzo (*Build.*) An imitation marble formed of Keene's cement and various colouring matters, used for panels, pilasters, and columns. The process of manufacture is as follows: threads of manilla grass, floss silk, or other suitable fibres are dipped into a "slip" (*q.v.*) of Keene's cement, coloured to the tint of the veining desired. These are arranged on a sheet of plate glass or other smooth surface to form the markings. Another thin coat of "slip," tinted to the body colour of the marble to be imitated, is now poured on. The threads are then carefully picked out, leaving behind them the veining colours, and dry cement is sprinkled on to absorb superfluous moisture. This preparation forms a surface to which a canvas backing is attached to strengthen it, the whole being further strengthened by a coat of cement to the required thickness. When dry the slab is removed and polished.

Margarine (*Foods*). Manufactured chiefly from beef and mutton fat (a mixture of stearin, margarine, and olein). The beef fat is first finely minced and heated to about 100° F. The water and *débris* sink to the bottom, and the fat is run off as a clear yellow oil, and kept at a temperature of about 86° F. The stearin solidifies and the oleomargarine is separated as a liquid, filtered, pressed, churned up with milk, coloured with annatto, cooled with ice, and is then ready for sale. By the Margarine Act, 1887, it may only be lawfully sold under certain conditions. Every package or parcel of margarine must be marked in capital letters not less than ½ in. long, and no other printed matter shall appear on the wrapper (section 6). All margarine manufactured or imported must be consigned as margarine (section 8). The premises upon which margarine is manufactured must be registered with the local authority (section 9). By the Sale of Food and Drugs Act, 1899, section 8, no margarine must be sold which contains more than 10 per cent. of butter fat. Section 5 extends provisions relating to margarine to margarine cheese.

Margery's Fluid. A solution of copper sulphate used to preserve timber.

Margin (*Build.*) The part of each slate on a roof exposed to the view.

Marigold Window (*Architect.*) *See* ROSE WINDOW.

Marine Boiler (*Eng.*) These are either cylindrical boilers of the type known as the SCOTCH BOILER (*q.v.*) or of the WATER TUBE type, such as the Belleville, Babcock & Wilcox, etc. *See also* BOILERS.

Marine Compass. A form of magnetic compass (*q.v.*) suspended by pivoted rings in such a manner as to remain as horizontal as possible during the motion of a ship. In modern ships the magnetic effects due to the iron in the vessel are corrected by fixing compensating masses of iron in suitable positions.

Marine Denudation (*Geol.*) *See* DENUDATION.

Marine Deposits (*Geol.*) Sediments of various kinds which are left on the floor of the sea. They may be classed as (1) Pelagic Deposits, which have been formed in deep water far from the land; (2) Thalassic Deposits, formed also in clear water, but nearer the shore; and (3) Terrigenous Deposits, which represent materials of mechanical origin left not far from the land, and which have been transported from it by the action of water in motion. The siliceous Radiolarian Ooze is a good example of the first; many Foraminiferal Oozes belong to the second category; while the third embraces the Glauconitic Sands, coral muds, and the various sandy and muddy deposits that are left within a few miles of the shore.

Marine Engine (*Eng.*) Modern marine engines are almost invariably compound engines, with two, three, or sometimes four inverted cylinders, in which the steam is expanded in succession. *See* STEAM ENGINE. The latest development is the use of the STEAM TURBINE, as in the *Queen* (Channel service), *Edward VII.* (Clyde), and certain yachts and torpedo boat destroyers.

Marine Glue. A cement containing rubber, shellac, and oil. It is melted and applied hot to wood and other materials where a watertight joint is required.

Marinoni Machine (*Print.*) *See* TYPOGRAPHY.

Marking Gauge (*Carp., etc.*) A short rod of wood having a steel marking point projecting at right angles near one end; on the rod slides a block forming a guide or "fence," which can be fixed in any required position. Used for marking a single line parallel to and at a given distance from the edge of a piece of wood. *Cf.* MORTICE GAUGE.

Marking Ink. *See* INKS.

Marking Out (*Eng.*) The process of marking on a piece of work the principal lines, centres, and measurements of the finished article.

Mark of Cadency *or* **Difference** (*Her.*) A device adopted to distinguish different members of the same family who bear the same arms. *See* LABEL.

Marks (*Met., Eng.*) The brands, such as B, BB, etc., which denote the quality of metal.

Marks of Reference (*Typog.*) *See* NOTES.

Marl (*Geol.*) In text books marl is generally defined as a "calcareous clay"; in practical geological work the term is almost universally applied to any half-indurated clay, which readily crumbles to small fragments and eventually forms into clay of the ordinary type after exposure to the weather. The marls of the New Red or of the Old Red rock are typical examples. The clay which, mixed with shells and other calcareous matter, forms at the bottom of some lakes, is distinguished as SHELL MARL. *See also* BRICKS.

Marquetry. A method of decoration effected by inlaying with pieces of wood, metal, and other materials of different colours placed in juxtaposition, and arranged to form various patterns. Buhl furniture is an example of this style of decoration.

Mars (*Astron.*) Distance from sun, 141,500,000 miles; diameter, 4,230 miles; periodic time, 687 days; time of rotation, $24\frac{1}{2}$ hours. It has two small satellites (Phobos and Deimos). Periods $7\frac{1}{2}$ hours and $30\frac{1}{4}$ hours respectively.

Marsh Gas (*Chem.*) A common name for METHANE (*q.v.*)

Marsh's Test (*Chem.*) A test for arsenic and antimony depending on the production and behaviour of their compounds with hydrogen. The substance to be tested must be in solution or be soluble; if it is mixed with organic matter, this must be destroyed, for example, by gentle warming with hydrochloric acid and potassium chlorate, and subsequent removal of all traces of chlorine and chlorine oxyacids. A compound like arsenious sulphide must be oxidised to arsenic acid by nitric acid, and excess of the latter removed by evaporation, because the sulphide is insoluble in the reagents employed, while arsenic acid is readily soluble. Zinc or magnesium free from arsenic is placed in a flask fitted with delivery tube and thistle funnel. The delivery tube is attached to a tube of calcium chloride to dry the escaping gases, and the drying tube is attached to a piece of hard glass tubing, narrowed to a jet at the further end. Dilute hydrochloric acid freed from arsenic (this can be done by previously heating the acid with clean strips of copper) is poured down the thistle funnel on to the zinc or magnesium. With zinc, if the action will not begin, a little platinum chloride may be added. The apparatus is now left till the hydrogen which is generated has displaced all air from the apparatus. Now the solution to be tested is poured in, and some of the hydrogen, instead of being set free as such, reduces the arsenic or antimony compound to hydride, AsH_3 or SbH_3, which escapes with the excess of hydrogen. If a fair amount of arsenic or antimony is present, the hydrogen and hydride may be lighted at the tip of the hard glass tube, and a cold porcelain surface held over the flame. The incomplete air supply caused by the porcelain burns the hydrogen of the hydride to water, while most of the arsenic or antimony, if the flame is not large, is deposited on the porcelain. This deposit is soluble in bleaching powder solution if it is arsenic; insoluble if it is antimony. A drop of nitric acid dissolves it in both cases on warming, and silver nitrate added to the solution, followed by very cautious addition of ammonia, gives a reddish brown precipitate with arsenic, but not with antimony. If the amount of arsenic or antimony is small, the hard glass tube is heated, when the hydride is resolved into its elements, and a deposit of arsenic or antimony is obtained: with traces of these elements this process must go on for hours. The deposits can be distinguished by their appearance and by subliming them in a current of air when the arsenic forms crystals of arsenious oxide which can be identified under the microscope, while the antimony gives an amorphous deposit of oxide. This process can be made quantitative by comparing the arsenic deposit with that produced by a known amount of arsenic in a similar apparatus. Several substances interfere with the production of the hydrides, *e.g.* presence of iron, nitrates, nitrites, sulphuretted hydrogen. It is a very delicate test, but opinions vary as to its delicacy; it will detect $\frac{1}{250}$ of a milligram of arsenic, or, according to some, $\frac{1}{1000}$ of a milligram.

Martel de Fer (*Arms*). A hammer headed weapon, being a combination of the mallet and pick, one half of the head being shaped like the ordinary hammer or mallet, the other pointed like a pick. There were two kinds, the long handled and the short handled, the former used chiefly by horsemen. Used during the fourteenth and fifteenth centuries.

Martellato (*Music*). Hammered.

Marten (*Zool.*) A member of the polecat and weasel family (order, *Mustelidæ*). The PINE MARTEN (*Mustela martes*) yields a valuable fur, which is often sold as an inferior sable. The AMERICAN MARTEN (*M. americana*) also has a fur of great value.

Martensite (*Chem., Met.*) *See* IRON.

Martlet (*Her.*) The heraldic swallow, represented without legs and with long wings. It is used as a difference or mark of cadency for the fourth son.

Marver (*Glass Manufac.*) A polished plate of cast or wrought iron placed upon a wooden bench or stool. Used for consolidating and centreing the molten glass upon the blowing iron. *See also* GLASS MANUFACTURE.

Marziale, Alla Marsia (*Music*). In march time: martial.

Mascle (*Her.*) A lozenge, perforated or "voided."

Mascled Armour. A kind of mail armour consisting of lozenge shaped pieces of metal attached to a leathern tunic. Armour of this kind was worn by the Normans, and is depicted on the Bayeux tapestry.

Mask (*Photo.*) An opaque screen, often of black paper, or else of some varnish painted on, used to cut off part of a negative during printing.

—— *or* **Masque** (*Architect.*) An ornament used in cornices and in corbels in English architecture during the thirteenth and fourteenth centuries. In front elevation it is similar to a buckle, and its shadow on the wall resembles the profile of a human face. It is also known as a BUCKLE or NOTCH HEAD.

Masoned (*Her.*) When the dividing lines in the masonry of a building such as a castle or tower are represented, they are described as masoned.

Masonry. The preparation and fitting together of stones in the construction of buildings, walls, etc. Stonework as distinguished from brickwork. *See* ASHLAR *and* RUBBLE.

Mason's Mitre (*Build.*) In mason's work all mitres are worked in the solid; that is to say, the angle is formed from one piece of stone, so that there is no actual joint along the line at which the two mouldings meet.

Mass. Mass usually means the "quantity of matter" in a body. The dynamical measurement of mass is based upon the change in velocity (acceleration) produced in a given time by a given force, which acts on the body. Thus equal masses are those in which equal forces produce equal changes of velocity in equal times.

Mass Action (*Chem.*) If steam is passed over red-hot iron the magnetic oxide of iron and hydrogen are produced; if hydrogen is passed over red-hot magnetic oxide of iron, iron and steam are produced.

$$3Fe + 4H_2O \rightleftarrows Fe_3O_4 + 4H_2$$

At a certain temperature, and with a mixture of iron and magnetic oxide in certain proportions, and a mixture of hydrogen and steam in certain proportions, it is clear that just as much iron will be converted into magnetic oxide as is produced from the magnetic oxide. If now the value of the ratio $\frac{\text{steam}}{\text{hydrogen}}$ is increased by a small amount and again kept constant at its new value, the ratio $\frac{\text{iron}}{\text{magnetic oxide}}$ will be diminished by certain amount, but will again become constant at a smaller value. This kind of reaction is called a mass action, and most chemical actions are of this kind, *e.g.* (1) Reactions like the above with other metals besides hydrogen. (2) Dissociation of a compound AB when the dissociation products A and B are present with unchanged substance AB. (3) Double decomposition occurring in a homogeneous liquid, as in the case of alcohol and acetic acid, which form ethyl acetate and water, and are reproduced from these; or in the case of potassium sulphocyanate and ferric chloride in aqueous solution, which form ferric sulphocyanate and potassium chloride, and are reproduced from these. (4) A soluble salt in solution and a nearly insoluble salt partly exchange acids, as in the case of potassium carbonate and barium sulphate, which form potassium sulphate and barium carbonate, and are reproduced from these. Taking the last case, the following table will show the influence of time and mass of the potassium carbonate. The temperature is 100°, and at the beginning of the reaction one molecular proportion of barium sulphate was present and 500 molecular proportions of water. There are seven separate experiments, and the absolute amount of barium sulphate at the beginning is given in each.

Molecules K_2CO_3	Percentage of $BaSO_4$ decomposed.	Absolute initial amount of $BaSO_4$ in grams.	Time in hours.
1	8·5	1·2251	1
2	36·1	1·4023	109
3	56·9	1·2589	109
4	78·2	1·3068	109
5	96·2	1·3328	113
7·5	98·4	1·2604	112
7·5	97·1	1·3340	163

It is unfortunate that the amounts of barium sulphate were not absolutely the same in each experiment; still, the table is useful. To get an idea of the law of mass action, consider the homogeneous system obtained when one molecular proportion of acetic acid and ethyl alcohol are mixed at the ordinary temperature and left to stand at that constant temperature; ethyl acetate and water are formed, and these begin to reproduce the acid and alcohol, the first reaction gradually becoming slower and the second gradually quicker, until the speed of each is the same; then, as far as the amount of each of the four substances is concerned, there is no further change. We shall express this condition by saying the system is in equilibrium. Let x of a molecular proportion of alcohol be the amount transformed when we have equilibrium, x is evidently in our case a proper fraction. Then we may express the state of affairs by the following equation:

$$C_2H_5OH + CH_3COOH = (1-x)C_2H_5OH + (1-x)CH_3COOH + xCH_3COOC_2H_5 + xH_2O$$

The law of mass action for this case is

$$k(1-x)(1-x) = k'x \cdot x \text{ or } k(1-x)^2 = k'x^2$$

k is a constant called the affinity constant for alcohol and acetic acid, and k' is a similar constant for the ester and water. $(1-x)$ is called the "active mass" of the alcohol and acetic acid, and x the "active mass" of the ester and water. The active mass of a substance is now generally expressed by the number of gram molecules per unit volume of the system; this is called the concentration of the substance. The general equation for a system such as the above, where only one molecule of each substance reacts, is $k, p, q = k'. p', q'$. The general equation for any system which is homogeneous and in equilibrium, and for which the chemical equation is

$$\alpha P + \beta Q + \ldots = \alpha' P' + \beta' Q' + \ldots$$

is $kp^{\alpha}q^{\beta} \ldots = k'p'^{\alpha}q'^{\beta} \ldots$ where $p, q \ldots p', q' \ldots$ are the concentrations (gram molecules per litre) of $P, Q \ldots P', Q' \ldots$ The above formulæ hold for gases as well as liquids; only as the concentration of a gas is directly proportional to its pressure, pressures are usually substituted for concentrations. In all the above cases it is assumed that no other action occurs than that indicated; that is, the products of a reaction are assumed to be without action on the original substances. Cases of heterogeneous systems, such as that between iron, magnetic oxide, steam, and hydrogen, and that between barium sulphate, potassium carbonate, potassium sulphate, and barium carbonate, are treated on the assumption that the active masses (concentrations) of the solids are constant; that is, the iron and magnetic oxide in the first case have each a small and constant vapour pressure, and the barium sulphate and barium carbonate have each a small and constant solubility. Example: Chemical equation,

$$3Fe + 4H_2O \rightleftarrows Fe_3O_4 + 4H_2$$

Applying the general formula, we have $k_1 p^2 q^4 = k' p' q'^4$, where k and k' are the "affinity constants," p and p' are the vapour pressures of the solids, and q and q' the partial pressures of the steam and hydrogen respectively. Hence

$$\left(\frac{q}{q'}\right)^4 = \frac{k'p'}{kp^2} = \text{Constant}$$

$$\therefore \frac{q}{q'} = \text{Constant}$$

Deville found in two experiments:

$$\frac{q}{q'} = \frac{4 \cdot 6}{25 \cdot 8} \text{ and } \frac{q}{q'} = \frac{10 \cdot 1}{57 \cdot 9}$$
$$= 0 \cdot 178 \qquad = 0 \cdot 174$$

The error is well within the limits of experimental error.

Massicot (*Chem.*) *See* LEAD COMPOUNDS.

Mässig (*Music*). The German equivalent for MODERATO (*q.v.*)

Massive (*Min.*) The term applied to the mode of occurrence of a mineral which is found in large masses, as distinguished from crystals, granules, lamellæ, or other forms.

Mast (*Eng.*) Any vertical pole, such as the upright post in certain cranes. In electrical traction the pole carrying the trolley wheel which makes contact with the overhead wire is termed a mast.

Mastaba (*Architect.*) The common form of the ancient Egyptian tomb; its shape is that of a truncated pyramid. They each contained a chamber near the entrance, in which offerings were placed; several secret chambers, known as SERDABS; and an underground chamber, containing the mummy.

Master (*Art*). A term applied to the founder of a "school." One who is eminently skilled in some branch of art.

—— (*Eng.*) A term applied to various tools used either as standards or for the production of other tools to a standard size or pattern, *e.g.* a MASTER TAP (*q.v.*)

Master Clock (*Clocks*). The timepiece controlling and actuating by electricity a series of dial works, or "journeymen," at different points in the circuit. *See* INDICATOR DIAL.

Masterpiece (*Art*). A great and masterly work of art; a work which is superior to any other by the same person.

Master Tap (*Eng.*) A standard tap, used for making the dies used in cutting screw threads.

Master Wheel (*Eng.*) A large wheel, accurately divided, used for correctly dividing out the teeth when cutting gear wheels.

Mastic (*Botany*). A resin from the incised bark of the stem and branches of a Mediterranean tree, *Pistacia lentiscus* (order, *Anacardiaceæ*). Used in medicine and as a varnish.

—— (*Build.*) A cement made of powdered stone or bricks mixed with oil and driers.

Mat, Celtic *or* **Basket** (*Textile Manufac.*) A type of weave in which the warp and weft form small squares. Mats are of three kinds, namely, ordinary (*i.e.* squares of warp and weft equal in size), irregular, and twilled.

Match Boarding (*Carp. and Join.*) Boards each having a tongue worked on one edge and a groove on the other edge, so they may be fitted together. The tongues and grooves are cut by machinery, and the boarding supplied by the timber merchants ready for use. Often termed MATCHING.

Matchbox *or* **Pipe** (*Arms*). A metal tube carried by matchlock men to protect the lighted match with which they fired their weapon from the weather.

Matchlock (*Arms*). One of the early forms of hand gun used during the fifteenth century. It was fired by means of a slow match, which was fixed in a lever on the gun.

Match Plate (*Foundry*). A flat plate to each side of which one half of a pattern is attached; the mould is made in two halves by the two parts of the pattern. In certain classes of work this method saves considerable time.

Mate. An assistant or subordinate who assists a more skilled workman. The term is also used in its ordinary sense for men working together.

Maté (*Botany*). *See* ILEX

Matelasse (*Textile Manufac.*) French term for a type of figured mantle cloth in which the design or pattern may be formed entirely either by the warp or by the weft. In other types, both warp and weft show on the face of the cloth.

Matico (*Botany*). A powerful styptic drug consisting of the dried leaves of the plant *Piper angustifolium* (order, *Piperaceæ*).

Matrix (*Build., etc.*) The cementing material mixed with the aggregate for making concrete.

—— (*Typog.*) The copper mould or "strike" from which type is cast.

—— *or* **Matrice**, *pl.* **Matrices**. In a general sense, the mould or form in which anything is shaped. A die from which impressions in relief are obtained.

Matt (*Dec.*) Having a dull or lustreless appearance; used with reference to colours in distemper which are left unvarnished.

—— *or* **Regulus** (*Met.*) A mass of partly purified metal in some intermediate stage of the smelting process, especially applied to Copper when in the condition of Coarse Metal or Fine Metal. *See* COPPER *and* METALLURGY.

Matter. Matter is defined as (1) that which occupies space; (2) that which possesses inertia. Of the actual nature, constitution, or ultimate structure of matter no exact statements can be made.

—— (*Engrav.*) An implement in the form of a punch used by mezzotint engravers for "matting" or laying a light, *i.e.* darkening the parts of a plate where the lights are too high.

—— (*Typog.*) Set up or composed type.

——, **States of** (*Phys.*) Matter may exist in three different well marked states, as: (1) A SOLID. (2) A LIQUID. (3) A GAS (*q.v.*) Certain other transitional and less marked states are also observable under special conditions.

Matt Gold Size (*Dec.*) A size used in gilding where the surface is required to be dead, *i.e.* without gloss. It is sold ready for mixing with jelly size.

Maulstick (*Paint.*) A light stick about a yard long, held in the left hand and used by painters to steady and support the right hand when painting.

Mauritius Hemp (*Botany*). *See* FURCRÆA.

Maxilla (*Zool.*) (1) In vertebrates, a jawbone; (2) An appendage in the Crayfish and other Crustacea.

Maxima and Minima (*Math., Phys.*) A quantity which varies periodically and continuously (*e.g.* the sine of a constantly increasing angle) attains a certain value, at which it ceases to increase, and commences to diminish. This value is termed a MAXIMUM. After passing through this value, the quantity diminishes until it reaches a certain value, termed a MINIMUM, at which it commences to increase again. In a Sine Curve (*q.v.*) the successive maxima are equal, as are also the successive minima; but this is not necessarily the case.

Maximum and Minimum Thermometer. A form of thermometer possessing some device for recording the highest or lowest temperature registered by the instrument during some given observation. In many forms the recording device consists of an index, generally some small body which is readily pushed along the bore in one direction by the surface of the liquid, but which is left behind when the surface moves in the opposite direction. In RUTHERFORD'S form the maximum thermometer contains mercury, the surface of which is in contact with an index consisting of a short rod of iron or steel placed *outside* the mercury. The whole tube is horizontal, and the index is pushed along when the temperature rises, and is left behind when the mercury recedes as the temperature falls. The minimum thermometer contains alcohol, and an index is placed in the liquid. The tension of the surface of the alcohol causes sufficient force to be exerted on t[illegible] to draw it back as the temperature falls; as [illegible] temperature rises, the alcohol flows past the [illegible] i[illegible] long subject [illegible] pressure [illegible]ce. Thus [illegible] index [illegible]ins in the [illegible] occupied at the low[illegible] temperature registered [illegible] the thermometer was last set. The indexes may be brought into contact with the surface of the liquid by tilting the tube, or may be moved by a magnet. Other forms of apparatus are also used: in SIX'S THERMOMETER both indexes rest on the upper surface of a thread of mercury in a vertical U-tube, one end of which terminates in a bulb containing alcohol, which acts as the thermometer substance. In NEGRETTI & ZAMBRA'S THERMOMETER, which is a maximum thermometer only, there is a constriction in the bore through which the thread of mercury readily passes as the temperature rises; as the temperature falls again, the thread is interrupted at the constriction; the part below recedes into the bulb, but the part above remains in the position it occupied at the highest temperature, which is therefore easily read. This form of thermometer can be used in any position, and is therefore very suitable for use as a CLINICAL THERMOMETER for medical use.

Maximum Density of Water (*Phys.*) Water attains its maximum density at 4° C. *See* WATER and HOPE'S EXPERIMENT.

M.D. (*Music*). The right hand: the letters standing for the Italian *Man Diritta* and the French *Main Droite*. The equivalent in English is R.H.

Me (*Music*). The third note of the scale in the Movable Doh or Tonic Sol Fah System.

Mean. (1) Any quantity whose value is intermediate between two others. (2) An AVERAGE (*q.v.*)

Mean Free Path (*Phys.*) The mean or average distance which the molecules of a gas travel without coming into collision with other molecules.

Mean Noon (*Astron.*) The time at which the Astronomical Mean Sun (*q.v.*) crosses the meridian.

Mean Pressure (*Eng.*) The average pressure in a cylinder during the stroke. *See* INDICATOR DIAGRAMS, *etc.*

Mean Solar Day (*Astron.*) The interval between two successive mean noons (*q.v.*) This is the legal day observed in civil life, and its divisions give us the ordinary time of day. The latter differs from the Apparent Solar Time, which is shown on a sundial, by a small amount, termed the Equation of Time. The amount of this correction varies at different times of the year. In March, June, September, and December its value is zero; in February and August it has its maximum value, and ten minutes must be added to the Apparent Solar Time, or time by the sundial, to get the mean or legal time; in May and November the sundial time is in advance of the clock, and ten minutes must be subtracted from the former to obtain the Mean Solar Time.

Mean Sun, Astronomical. An imaginary point moving with uniform velocity round the Equator, and coinciding with the Dynamical Mean Sun (*q.v.*) at the points of intersection of the ecliptic and equator.

——, Dynamical (*Astron.*) An imaginary point moving with uniform velocity round the ecliptic, and always coinciding with the sun at perigee.

Measure (*Music*). A bar; that which is contained between two bar lines. Measure is the grouping of accent and non-accent, the bar line always preceding the strongest accent. *See* TIME.

Measurement. Measurement in general consists of the comparison of one magnitude with another, the latter constituting a standard of measurement. There are three fundamental standards, on which practically all measurements, however complex, ultimately depend—namely, the standards of Mass, Space, and Time. *See* STANDARDS OF MASS, SPACE, AND TIME, *and* WEIGHTS AND MEASURES. Measurements of mass are made by means of a BALANCE, SCALES, STEELYARD, SPRING BALANCE, etc. (*q.v.*) Measurements of length are commonly made by means of a graduated ROD, STAFF, RULE, SCALE, CHAIN, etc. (*q.v.*); more accurate measurements by means of CALIPERS, SCREW GAUGE, MEASURING MACHINE, READING MICROSCOPE, etc. (*q.v.*) Measurements of area are usually made by taking linear measurements and calculating the area by mensuration; measurements of volume may be made in the same way, or, in the case of fluids, by filling a vessel of known volume. Measurements of time may be made by comparison with the time of the swing of a PENDULUM (*q.v.*), the period of vibration of which is known from some previous observation. In ordinary measurements of time, in which a clock or watch is used, the pendulum (or its equivalent, the balance wheel) still furnishes the real unit of time, the mechanism serving for the purpose of recording the number of vibrations and also supplying the motive power by which the vibrations are maintained. The ultimate measurement of time depends entirely upon astronomical observations of the motion of celestial bodies; *e.g.* the transit (*q.v.*) of stars, the determination of noon, etc. Apart from the natural standards thus furnished, there is no definite unit of time whatever.

Measurement, Electrical. *See* AMMETER (*Appendix*), TANGENT GALVANOMETER, DYNAMOMETER, VOLTMETERS, RESISTANCE, WHEATSTONE BRIDGE, OHM'S LAW, *etc.*

Measurements of Temperature. Measurements of temperature are made in practice by the observation of certain physical changes produced in a suitable substance (termed the THERMOMETRIC SUBSTANCE) by changes of temperature. The chief physical properties utilised for thermometric purposes are as follows:

1. Volume of a liquid . (Common thermometers).
2. Pressure of a gas . } (Gas thermometer).
3. Volume of a gas . }
4. Length of a bar . . (Certain pyrometers).
5. Resistance of a conductor . . } (Platinum thermometer).
6. Electromotive force . (Thermo-electric couple).
7. Specific heat of a substance . . } (Indirect method).

(1) The common THERMOMETER consists of a capillary tube terminating in a bulb. A quantity of liquid (*e.g.* mercury or alcohol) is placed in the tube, sufficient to fill it when heated to a temperature slightly above the highest temperature to be observed by means of the instrument; the tube is sealed at the top while at this temperature. The FIXED POINTS are then found and marked on the tube. These are the levels at which the liquid stands in the capillary tube at certain standard temperatures; in ordinary cases the freezing point and the boiling point of pure water. The scale may now be constructed by dividing the distance between the marks on the tube into a convenient number of parts or DEGREES. *See* CENTIGRADE, FAHRENHEIT, *and* REAUMUR SCALES. The WEIGHT THERMOMETER also depends upon the variation in the volume of a liquid. If a bulb be completely filled by a weight w_0 of some suitable liquid at 0° C., and w_t the weight which fills it at a temperature $t°$, then the value of t is given by the equation

$$t = \frac{w_0 - w_t}{w_t}$$

(2 and 3) The GAS THERMOMETER depends upon the changes in pressure of a gas at constant volume, due to changes of temperature, or (less frequently) upon its changes of volume at constant pressure. Thus let P_0 and V_0 be the pressure and volume at 0° C., P_t and V_t the values at t°, and a the coefficient of increase of pressure at constant volume (or increase of volume at constant pressure); then

$$P_t = P_0 (1 + at)$$
$$V_t = V_0 (1 + at)$$

Thus if a be known and P (or V) be observed at 0° and at t°, the value of t may be readily found. The gas thermometer has a very wide range of temperatures, over which its readings are reliable. (4) A PYROMETER is a form of thermometer especially adapted to the measurement of very high temperatures. The early forms depended upon the measurement of the expansion of a bar of metal, porcelain, fireclay, etc. The indications of these instruments were very uncertain, and they are now replaced by the ELECTRICAL RESISTANCE THERMOMETER or PLATINUM THERMOMETER. (5) This depends upon the increase in the resistance of a platinum wire as the temperature rises. The rate of increase of resistance is very nearly a constant, and may be expressed to a first approximation by the equation

$$R_t = R_0 (1 + at),$$

where R_t equals the resistance at t°, R_0 the resistance at 0°, and a is the coefficient of increase of resistance with temperature. The coefficient may be found by observing the resistance of the instrument at 0° and 100° C. To obtain greater accuracy, a further correction (termed the "delta correction") must be introduced; this requires the use of a second constant, whose value may be found by measuring the resistance of the wire at a third known temperature. For this purpose the boiling point of sulphur (444·53° C. at the normal atmospheric pressure of 760 millimetres) is used as a standard. The platinum thermometer affords the best scientific method of measuring temperature; not only has it a very extensive range, but it is capable of detecting very minute changes; *e.g.* $\frac{1}{10000}$ of a degree Centigrade—a sensitiveness far beyond any liquid or gaseous thermometer. (6) A thermo-electric junction affords a very convenient, though less accurate, method of measuring temperatures. A "couple" consisting of two pieces of dissimilar metals in the form of wire twisted together is connected in series with a suitable galvanometer. The deflection of the galvanometer will depend upon the E.M.F. at the junction, and the scale may be graduated to read directly in degrees within a wide range. The thermo-electric couple has been much used in experimental work in metallurgy, and is now being applied to many practical purposes in the same science. (7) The remaining method only gives an approximate measurement. A solid of known specific heat (*q.v.*) is heated up to the temperature which it is desired to measure (*e.g.* by placing it in a furnace), and, when hot, is dropped into a vessel of water or other liquid of known specific heat. From the rise in temperature of this liquid the heat given out by the solid can be found, and hence its temperature at the instant when it was introduced into the liquid. A correction must be made for the amount of liquid which was turned into vapour by the hot solid at the time of first entering the liquid.

Measures. *See* WEIGHTS AND MEASURES.

Measuring Machine (*Eng.*) An appliance resembling in principle a large SCREW GAUGE (*q.v.*), introduced by Whitworth for the accurate comparison of small standards of length by means of end measurement.

Meat (*Foods*). As an article of diet meat furnishes proteid, fat, and salts. As a rule "white meat," such as fowl and rabbit, contains less nitrogen, and is more tender and digestible than "red meat," such as beef, mutton, and game. The muscles of this latter class of meat should be firm and elastic to the touch; moist, but not wet; of a deep red colour except in the case of veal and pork; and marbled with fat. The fat should be firm and whitish yellow in colour, and free from bloodstains. The marrow of the bones should be light red. If putrefaction has begun the meat is pale and soft; a knife or skewer thrust in and rapidly withdrawn will smell offensively. *See* FOODS.

Mechanical Air Pumps. *See* AIR PUMPS.

Mechanical Characteristic (*Elect. Eng.*) A curve showing the ratio of TORQUE and SPEED (*q.v.*) in an electric motor.

Mechanical Cut Out (*Elect. Eng.*) Any arrangement for breaking a circuit which is not worked electrically.

Mechanical Deposits (*Geol.*) This term includes various forms of sedimentary rocks, such as sandstones, breccias, conglomerates, boulder clays, etc., in

contradistinction to limestones, coal seams, oil shales, etc., and rocks of eruptive origin.

Mechanical Engineering. A comprehensive term for the science and art of designing, casting, forging, machining, fitting and erecting machines, metal structures, etc.

Mechanical Equivalent of Heat. *See* JOULE'S EQUIVALENT.

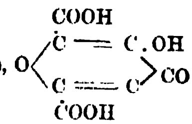
Mechanical Operations. Operations carried out by a machine, either entirely automatic or partly worked or controlled by hand.

Mechanical Wood (*Paper Manufac.*) A term applied to wood pulp prepared by the mechanical process. *See* WOOD PULP.

Mechanics. The science dealing with forces and their effects upon matter.

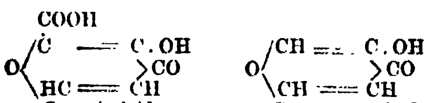
Mechanism. A term often used synonymously with MACHINE (*q.v.*): the arrangement and relation of the parts of a machine. Scientifically it is applied to an ideal or theoretical combination of moving parts having the kinematical properties of a machine or of some portion or "element" thereof.

Meconic Acid (*Chem.*),



(2:6-dicarboxy-3-hydroxy-γ-pyrone).

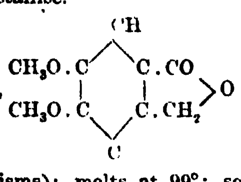
A white crystalline solid (scales or prisms) which contains 3 molecules water of crystallisation; soluble in water, more so in alcohol; gives a red colour with ferric chloride; boiled with water it gives comenic acid; heated alone, it yields first comenic acid, then pyromeconic acid—



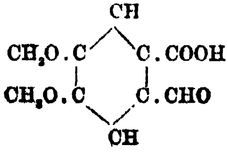
Comenic Acid. Pyromeconic Acid.

It occurs united with the alkaloids in opium, and is extracted from the latter by treatment with warm water, neutralisation with chalk, concentration of the solution, and addition of calcium chloride, when calcium meconate crystallises out; from the salt the acid is obtained by boiling with hydrochloric acid and allowing to crystallise.

Meconin (*Chem.*),



White crystals (prisms); melts at 99°; soluble in alcohol; occurs in opium; it is obtained when narcotine is reduced by zinc and sulphuric acid; also when opianic acid is reduced by sodium amalgam. Opianic acid has the formula



Mediæval. In regard to art this generally applies to the period between the twelfth and sixteenth centuries. Historically speaking, it covers a period of about a thousand years, *viz.* from the middle of the fifth century to the capture of Constantinople by the Turks in 1453.

Mediant (*Music*). The technical name for the third degree of the scale, lying midway between tonic and dominant.

Medicinal Soaps. That class of toilet soaps which are specially made for benefiting the skin, or to assist in curing certain diseases, such as tar soap, turpentine soap, and other special mixtures used for eczema, cases of rough skins, etc.

Medium (*Paint.*) The liquid vehicle with which pigments are mixed for painting, *e.g.* linseed oil, magilp.

—— (*Paper Manufac.*) Printing paper measuring 24 by 19 in. Writing paper measuring 22 by 17½ in.

Medlar (*Botany*). The medlar is the fruit of *Mespilus germanica* (order, *Rosaceæ*). The five large sepals surmounting the fruit are distinctive of the genus.

Medulla (*Biol.*) (1) A term often applied to a substance forming the internal portion of an organic structure, *e.g.* the PITH of a plant stem, the pithlike substance in the axis of a feather. (2) The MEDULLA OBLONGATA is the hinder portion of the brain.

Meerschaum (*Min.*) A hydrous silicate of magnesium, $2MgO.3SiO_2.2H_2O$. Silica = 60·8, magnesia = 27·1, water = 12·1 per cent. Amorphous; white or greyish; can be scratched by the finger nail. It is used principally for the making of pipes; in Algiers as a substitute for soap; and as a building stone in Spain. The best samples are from the Levant and Asia Minor.

Meeting Rails (*Joinery*). Rails that meet together, *e.g.* the rails of double hung sashes.

Meg- *or* **Mega.** A prefix indicating that the unit, etc., is multiplied one million times, *e.g.* MEGOHM, one million ohms.

Megalithic (*Architect.*) Composed of large stones. *See* PREHISTORIC ARCHITECTURE.

Megohm (*Elect.*) One million OHMS (*q.v.*)

Megohm Standard (*Elect.*) A standard coil of one megohm resistance. Used in measuring high resistances, such as those of insulating materials.

Meissen. *See under* DRESDEN CHINA.

Meizoseismic. A term applied to the line or curve of maximum disturbance effected by an earthquake.

Melanite (*Min.*) A black variety of Garnet (*q.v.*)

Melanterite (*Min.*) Hydrous sulphate of iron, $FeSO_4.7H_2O$. Sulphuric acid = 28·5, water = 45, ferrous oxide = 26·5 per cent. Monosymmetric; green to white when fresh; often yellow or brown after exposure. Often occurs as a pulverulent incrustation. A frequent product of the decomposition of Pyrites. In quantity at Goslar in the Harz, and in Ohio. *See also* COPPERAS.

Melaphyre (*Geol.*) A term which was formerly used to denote a basalt that has undergone changes in composition through the prolonged action of percolating waters.

Melde's Experiment (*Sound*). An experiment for showing the laws of vibration of strings. One end of a string passes over a pulley, and is attached to a

weight; the other end is attached to the prong of a large tuning fork, by means of which the string is set in vibration.

Mellow (*Carp.*) A term applied to timber which is thoroughly dry and in good condition for working.

Mellowing (*Leather Manufac.*) Applied to tan liquors means ageing and souring of the liquor with diminution of astringency. Applied to leather, means the softening of hard, harsh leather. This is generally attained by allowing the leather to lie in pile to absorb moisture, the process being assisted by damping and stretching or staking.

Melody (*Music*). An orderly succession of different single sounds.

Melting. The fusion of a substance. Distinguished from SMELTING (*q.v.*), which is fusion, accompanied by chemical or other changes in the substance which is being treated.

Melting Point (*Phys., etc.*) The temperature at which a substance fuses under ordinary conditions of pressure.

——, **Effect of Pressure on** (*Phys.*) Substances which expand on melting have their melting point raised by increase of pressure; those which contract on melting (*e.g.* ice) have their melting point lowered by pressure.

Melting Pot (*Glass Manufac.*) A crucible used in GLASS MANUFACTURE (*q.v.*)

—— (*Plumb.*) An iron pot for melting lead and solder.

Member (*Architect.*) A moulding; *e.g* (1) An architrave may consist of two or more members. (2) The crowning moulding of a cornice is its upper member.

—— (*Eng., etc.*) A single portion of a structure or machine.

Membered (*Her.*) Said of the beak and legs of a bird when they differ in tincture from the body.

Membrane (*Biol.*) Tissue in the form of a thin sheet.

Menaccanite (*Min.*) A variety of ILMENITE (*q.v.*)

Mending (*Cloth Manufac.*) The operation of repairing broken threads and picks and defective places in the piece after weaving. It may involve the insertion of lengths of thread, the mender having carefully to follow the order of interlacing in weaving.

Mending Up (*Foundry*). *See* MAKING UP.

Mending Up Piece (*Foundry*). A strip of wood (or metal) which is bent to the shape of the edge of a mould, and held in place while sand is rammed against it to repair a broken edge, in MENDING UP (*q.v.*)

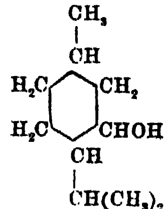
Menhirs (*Architect.*) *See* PREHISTORIC ARCHITECTURE.

Menilite (*Min.*) A variety of OPAL from near Paris; it occurs in rounded concretionary masses of a liver colour.

Meno (*Music*). Less; *meno mosso*, less movement: somewhat slower.

Mensuration. The calculation of the areas and volumes of figures and solid objects.

Menthol (*Chem.*),



(Methyl-1-isopropyl-4-cyclohexanol-3).

A white crystalline solid smelling of peppermint; melts at 42°; lævorotatory; very soluble in alcohol and in chloroform. On reduction it yields hexahydrocymene; on oxidation it yields menthone (*q.v.*); dehydrating agents convert it into menthene

$$CH_3.CH\left\langle\begin{smallmatrix}CH_2 - CH \\ CH_2 - CH_2\end{smallmatrix}\right\rangle C.CH(CH_3)_2.$$

Menthol occurs in oil of peppermint (50 to 65 per cent.), from which it is prepared by freezing. Used in medicine because it produces local anæsthesia.

Menthone (*Chem.*) The ketone corresponding to menthol (*q.v.*); it is a liquid smelling of peppermint and having a bitter taste; boils at 206°. It occurs along with menthol in oil of peppermint, and can be separated from this by conversion into menthone oxime. It is prepared from menthol by oxidation with potassium dichromate and sulphuric acid.

Mentonière (*Arm.*) A piece of defensive armour which was generally attached to the breastplate, and formed a protection for the neck, chin, and the lower half of the face. Literally a chin piece.

Mercaptans (*Chem.*) Alcohols in which the oxygen is replaced by sulphur. They are also called thioalcohols or hydrosulphides, *e.g.*

CH_3OH	CH_3SH
Methyl Alcohol.	Methyl Mercaptan.

Ethyl mercaptan, commonly called mercaptan, is the most important member of the series, and it is described as typical of all other mercaptans. It is a colourless liquid with peculiar garlic smell, which is very persistent; boils at 36·2°; soluble in water; the solution deposits crystals, $C_2H_5SH18H_2O$, on cooling. On oxidation with nitric acid it yields ethyl sulphonic acid. The hydrogen of the hydrosulphide group is easily replaceable by metals when mercaptides are formed; it was on account of the ease with which ethyl mercaptan unites with mercuric oxide to form mercury mercaptide, $(C_2H_5S)_2Hg$, that it received the name mercaptan. Mercaptan condenses with aldehyde in presence of hydrochloric acid to form a mercaptal ethidene mercaptal—

$$CH_3.CH\left\langle\begin{smallmatrix}SC_2H_5 \\ SC_2H_5\end{smallmatrix}\right.$$

Mercaptan is used in the manufacture of sulphonal (*q.v.*) Methyl and ethyl mercaptans are decomposition products of albumins. Mercaptan is prepared by distilling solutions of potassium hydrosulphide and calcium ethyl sulphate; it can also be prepared by distilling alcohol with phosphorus pentasulphide. Aromatic mercaptans can be prepared by reduction of the sulphonic acid chlorides, *e.g.*

$$C_6H_5SO_2Cl \xrightarrow[H]{} C_6H_5SH.$$

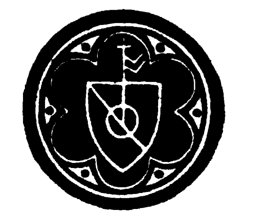
Mercerisation. In the year 1844, John Mercer, a Lancashire calico printer, made the discovery that when a cotton fabric is immersed in a cold solution of caustic soda or potash, within certain limits of

concentration, the strength of the fibre and its power of attracting colouring matters are considerably increased. This alteration in properties is accompanied by a contraction of the material which may even amount to 25 per cent. of its area. Although Mercer patented his discovery in 1850, and was offered £40,000 by a French firm for the patent rights (an offer which he refused), the process was not worked successfully in his day on a commercial scale, owing to the contraction of the fabric and the cost of working. This treatment with caustic soda became known as MERCERISING; but the process remained almost purely theoretical in its interest until it was revived nearly fifty years later for the production of crimped or *crêpon* effects. When certain portions of a cotton fabric are printed with, or otherwise subjected to, the action of caustic soda solutions of a certain strength, whilst other parts are protected from this action, the treated portions become mercerised and contract, which brings about a crinkling or puckering of the untreated areas. The operation to which the name "mercerising" is chiefly applied at the present time dates from 1895. In that year the patents of THOMAS & PREVOST set forth that if the contraction of cotton fabrics or yarns, due to mercerisation, be prevented by subjecting the material to a sufficient tension during the operation, the cotton is not only made stronger and capable of being dyed more deeply with the same quantity of colouring matter, but it also acquires an enhanced lustre, resembling, though not equal to, that of silk. The validity of Thomas & Prevost's patents was successfully contested on the ground that the invention had been anticipated in the English patent granted in 1890 to LOWE, who appears, however, not to have appreciated the full import and commercial value of the discovery. This mercerising or "lustreing" process is now carried out on a very large scale on cotton yarn and cloth, and mercerised cotton has replaced silk in certain of its industrial applications. Various types of machine exist for performing the necessary operations, but whatever the particular method of working, the material is treated with caustic soda by immersion or by sprinkling while in a stretched condition, well washed with water without relaxing the tension, and passed through an acid bath to complete the removal of alkali. If desired, a silk-like "scroop" is imparted by passages through successive baths containing soap solution and dilute acid. Only certain varieties of cotton yield a high degree of lustre by this treatment, *viz.* the long-stapled Egyptian and Sea Island cottons. Caustic soda below 15° Tw. has no mercerising action; the best results are obtained with a lye of 45° to 55° Tw. (S.G. 1·22 to 1·27) at a temperature not exceeding 70° F. The duration of the treatment has little influence. The CHEMICAL CHANGE involved in mercerisation is the formation of a stable cellulose hydrate, $(C_6H_{10}O_5 \cdot H_2O)_n$. The appearance of the fibre undergoes alteration, the cell walls thicken, the central cavity almost disappears, and the fibres become much rounder. In DYEING mercerised cotton the direct dyestuffs are chiefly employed, since mordanting operations usually bring about a diminution of the lustre; for very bright shades the direct dyes are "topped" with basic colours. The lustre of mercerised fabrics is frequently increased by means of mechanical finishing operations—*e.g.* the SCHREINER FINISH, which consists of passing the material under a heated roller engraved with a large number of very fine lines; this breaks up the surface of the material into innumerable minute reflecting surfaces. Other mercerising agents besides caustic soda have been suggested; Mercer himself mentioned sulphuric acid and zinc chloride. Analagous processes applicable to wool and silk have also been described as "mercerisation," *e.g.* a treatment with caustic alkali at 32° F., but these have not found any extended application.—R. B.

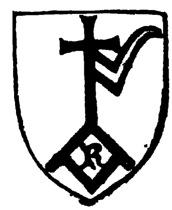
Mercerised Cotton. *See* CELLULOSE *and* MERCERISATION.

Merchant Iron. Wrought iron bar, ready for putting on the market.

Merchant Marks (*Archæol.*) From earliest times it has been found necessary to have some distinguishing personal mark by which to identify an owner. With regard to those who had the right to wear coat armour, there was no difficulty; the heralds took care that only those entitled to have armorial bearings used them. With respect to citizens and merchants, there arose the custom of identifying their goods by what are now termed "merchant marks." Hence we find the following in the Harleian MSS.: "Theys be none Armys, but a marke as merchaunts use, for euery man may take hym a marke; but not armys without a herawde or purcyuante." Though alluded to in a slighting manner in the foregoing extract, yet these marks were protected by the laws of the realm equally as jealously as the coats of arms. They occasionally appear on monuments, etc., in conjunction with coats of arms. The marks originally showed the deep

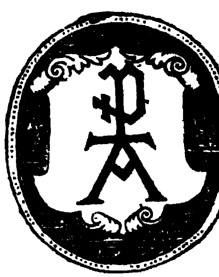


GREVEL, CHIPPING CAMPDEN, 1401.



PAGGE, CIRENCESTER, 1440.

religious feeling which underlay all the transactions of everyday life, and generally consisted of a cross or a variant of the same. Another frequent form was shaped like the Arabic numeral 4, in which the cross may be again noted. The woolstaplers looked to St. John Baptist as their patron; consequently they utilised his emblems, the lamb and cross with streamers. The initials of the owner were often added, and in later times, when the cross disappeared, monograms and conventional forms were used, which survive at the present time under the designation of Trademarks.



PARKER, IPSWICH, 1590.

Mercury (*Astron.*) The planet nearest the sun. Distance from sun, 35,750,000 miles; diameter, about 3,000 miles; periodic time, 88 days.

—— (*Chem.*) Hg. Atomic weight, 200·3. A silvery white liquid; melts at −39°; boils at 358°. It has a vapour density equal to half its atomic weight, from which it is concluded that mercury has a monatomic molecule. It slowly combines

with oxygen at a temperature near its boiling point, forming the red oxide in crystalline form; with many other elements, it unites even at the ordinary temperature—for example, with the halogens and sulphur and many metals. Combinations of mercury and other metals are called amalgams; some of them appear to be definite compounds. The action of acids is as follows:—Hydrochloric acid—no action; hydriodic acid forms the iodide which dissolves in the acid; nitric acid—cold and dilute, forms with excess of mercury mercurous nitrate, the hot acid in excess forms mercuric nitrate; sulphuric acid—hot and concentrated, forms mercurous sulphate if the metal is in excess, mercuric sulphate if the acid is in excess. Mercury occurs naturally chiefly as sulphide, which is called cinnabar; to a much smaller extent it occurs free. It is obtained from the ore by a simple roasting process, $HgS + O_2 = Hg + SO_2$: but elaborate condensing arrangements are required to recover all the vapour. Commercial mercury or mercury which has been much used in the laboratory is impure; such mercury is purified by distilling under greatly reduced pressure or by allowing it to stand under dilute nitric acid, when less easily oxidised metals than mercury go into solution, because such metals throw out mercury from solutions of its salts. Mercury is largely used in the construction of scientific apparatus, such as thermometers, barometers, air pumps, standard cells, etc.; it is also used in medicine in various forms, *e.g.* grey powder is mercury and chalk; blue pill is mercury, lard, and suet.

—— (*Min.*) This element is found native in a disseminated state in some shale and in disintegrated granite. The chief localities are Almaden in Spain, and Idria in Austria. When artificially frozen it crystallises in the cubic system. The chief ores of mercury are Amalgam, Cinnabar, and Calomel. Cinnabar alone is commercially important as an ore.

Mercury Air Pump. *See* AIR PUMPS.

Mercury Break (*Elect.*) A device for making and breaking a current by means of a vibrating conductor, which is caused to dip into a vessel of mercury.

Mercury Compounds (*Chem.*) Mercury forms three classes of compounds, namely the mercurous compounds, the mercuric compounds, the mercury ammonium compounds. *Mercurous Compounds*:—MERCUROUS OXIDE, Hg_2O, is a black powder, easily decomposed by light or on heating to mercury and mercuric oxide. It is obtained by the action of caustic soda or potash in slight excess on a mercurous salt. MERCUROUS CHLORIDE, Hg_2Cl_2, commonly called CALOMEL, is a yellowish white powder which sublimes without melting or heating. The vapour density of ordinary calomel is 118, or half that required by the formula Hg_2Cl_2: this is due to dissociation into mercuric chloride and mercury. When calomel is dried by allowing it to remain in a vapour density apparatus containing phosphorus pentoxide for several days, its vapour density is nearly normal. Calomel is practically insoluble in water (3 parts in 1,000,000); it is soluble in boiling hydrochloric acid, but this is due to conversion to mercuric chloride. For action of caustic soda or potash see the OXIDE. Ammonia turns it black, owing to formation of a mixture of dimercurammonium chloride and mercury. It is obtained (1) by precipitating a solution of mercurous nitrate with hydrochloric acid in slight excess, filtering and well washing the precipitate; (2) by subliming an intimate mixture of mercuric chloride and mercury and thoroughly washing the sublimate. Calomel is used in medicine. MERCUROUS NITRATE, $Hg_2(NO_3)_2$: A white crystalline solid; the crystals contain $2H_2O$; soluble in a small quantity of water; hydrolysed by much water, forming a basic nitrate. The ordinary solution is made by adding a little nitric acid to the water in which it is to be dissolved. It is the only common soluble mercurous salt. MERCUROUS IODIDE, Hg_2I_2: Yellow tetragonal tablets; sublimes on heating gently; rapidly heated it decomposes, with liberation of mercury. Prepared by boiling a solution of mercurous nitrate containing a little nitric acid with excess of iodine, and allowing the clear liquid to crystallise. The green compound obtained by precipitating mercurous nitrate with potassium iodide is probably not pure, as mercurous iodide is decomposed by potassium iodide, $Hg_2I_2 + 2KI = K_2HgI_4 + Hg$. *Mercuric Compounds*:—MERCURIC OXIDE, HgO, also called RED PRECIPITATE, exists in two forms, yellow and red. According to Ostwald the difference is due to the yellow form being more finely divided than the red. According to Schoch the two forms are really distinct, the yellow form crystallising in square tablets and the red in prisms; also the yellow form has a higher dissociation pressure than the red. It is slightly soluble in water; decomposed on heating. The yellow variety is more active chemically than the red; for example, it gives chlorine monoxide with chlorine, while the red does not. Acids yield corresponding mercuric salts. The yellow oxide is obtained by adding a solution of caustic soda or potash to a solution of mercuric chloride. The red oxide is obtained by heating mercuric nitrate alone, or, more economically, by heating an intimate mixture of the nitrate and mercury. Both oxides are used in medicine. MERCURIC CHLORIDE, $HgCl_2$, also called CORROSIVE SUBLIMATE: A white crystalline solid (needles). Melts at 288°; boils at 303°. Moderately soluble in water, much more soluble in ether and alcohol. Its aqueous solution has about the same electrical conductivity as water, so that it is only feebly ionised. This accounts for several peculiarities in its chemical behaviour; for example, it is not decomposed by concentrated sulphuric or nitric acids. It is very poisonous. Its solution coagulates albumen; hence the use of white of egg as an antidote in corrosive sublimate poisoning, the latter forming an insoluble compound with the former. With solution of caustic soda or potash it gives the yellow oxide; with ammonia it gives a white precipitate, $NHg_2Cl.NH_4Cl$. *See below*. Its solution dissolves mercuric oxide, forming various oxychlorides. Hydrochloric acid readily dissolves mercuric chloride, forming the compound $HHgCl_3$. Mercuric chloride forms many double salts with the alkaline chlorides, *e.g.* $KHgCl_3$ and K_2HgCl_4, and similar salts with NaCl and NH_4Cl, which are more soluble than mercuric chloride in water. $(NH_4)_2HgCl_4 . H_2O$ is SAL ALEMBROTH. Mercuric chloride is prepared by subliming a mixture of common salt and mercuric sulphate, to which a little manganese dioxide has been added, to prevent the formation of calomel from any mercurous sulphate which may be present in the mercuric sulphate. It can be obtained by the action of chlorine on mercury, and therefore of *aqua regia* on mercury. *Also see above*. It is very largely used as an antiseptic and bactericide. MERCURIC IODIDE, HgI_2: Exists in two forms—yellow rhombic prisms and red quadratic prisms, the latter being the stable form at

ordinary temperatures. The transition temperature is 126°; that is, above this temperature the yellow is the more stable form, and below it the red. When the vapour of mercuric iodide is condensed, or when the iodide is formed by precipitation, the yellow form is produced first, and the change from yellow to red is accelerated by light; when the vapour is condensed in the presence of crystals of each form, then both forms are produced. At the boiling point of liquid air the red form becomes orange, and the yellow form white. Melts at 253°. Solubility in water, 0·5 parts in 1,000,000 at 18°; much more soluble in hot solution of potassium iodide or hot concentrated hydrochloric acid, from which it can be crystallised; soluble in alcohol. It forms many double salts; for example, K_2HgI_4. It is prepared by grinding mercury and iodine together in a mortar in presence of a little alcohol, also by precipitating a solution of mercuric chloride with potassium iodide. It is used in medicine. MERCURIC NITRATE, $Hg(NO_3)_2$: A white crystalline solid, soluble in water, containing a little nitric acid. Forms basic salts with water, *e.g.* $Hg(NO_3)_2 2Hg(OH)_2$. On heating it gives the red oxide. It is formed by dissolving mercury in hot nitric acid, using small excess of the latter, and crystallising by allowing to stand over sulphuric acid. Used in medicine. MERCURIC SULPHATE, $HgSO_4$: A white crystalline solid, soluble in water, containing sulphuric acid. Decomposed by water, forming basic salts, *e.g.* $HgSO_4 2Hg(OH)_2$. Obtained by boiling mercury with excess of sulphuric acid. Used in preparation of artificial indigo. *See* INDIGO. MERCURIC SULPHIDE, HgS: The natural sulphide is called "cinnabar," and the artificial variety, prepared for use as a pigment, is called "vermilion." Mercuric sulphide exists in two forms: a black amorphous form and a red crystalline form which is more stable than the black form. When the black form is sublimed out of air it passes into the red form; the same change occurs when the black form is allowed to stand in a solution of an alkaline sulphide, the reason being that the black variety is more soluble in such a solution than the red variety, so that the solution is always saturated with respect to the black and supersaturated with respect to the red form. On heating out of air, mercuric sulphide sublimes without melting; its vapour density is below the normal, so that dissociation occurs. Heated in air it gives mercury and sulphur dioxide. Heated with diluted nitric acid it forms a white compound, $Hg(NO_3)_2 2HgS$. This compound and a similar white compound, $HgCl_2 2HgS$, are formed when sulphuretted hydrogen is passed into a solution of the nitrate and chloride respectively, in amount insufficient for complete precipitation: both are decomposed by excess of the gas. *Aqua regia* converts the sulphide into chloride with separation of sulphur. The black form is obtained by grinding mercury and sulphur together, or by precipitating a solution of the chloride with excess of sulphuretted hydrogen. The red form is obtained from the black, as mentioned above. It is used as a paint. *See* VERMILION. MERCURIC CYANIDE, $Hg(CN)_2$: A white crystalline solid (prisms), easily soluble in water. The aqueous solution is a non-conductor of electricity, and it shows the normal lowering of the freezing point; so the salt is not ionised, and therefore does not give the ordinary tests for mercury or for a cyanide. It is decomposed by sulphuretted hydrogen, also by hydrochloric acid. On heating, it decomposes into mercury and cyanogen, a part of the latter polymerising. It combines with mercuric oxide to form a basic cyanide, $HgO . Hg(CN)_2$, and forms many double salts, *e.g.* $K_2Hg(CN)_4$. It is obtained by boiling Prussian blue with mercuric oxide and water,

$$2Fe'''_4\{Fe''(CN)_6\}_3 + 21HgO + 21H_2O = 18Hg(CN)_2 + 14Fe(OH)_3 + 3Hg,$$

also by boiling potassium ferrocyanide with mercuric sulphate and water,

$$2K_4Fe(CN)_6 + 7HgSO_4 = 6Hg(CN)_2 + 4K_2SO_4 + Fe_2(SO_4)_3 + Hg,$$

and very conveniently by dissolving yellow mercuric oxide in a slight excess of hydrocyanic acid (dilute). Mercury combines with many alcohol radicals. MERCURY METHYL, $Hg(CH_3)_2$, may be taken as an example of these compounds. It is a colourless liquid; boils at 95°. Its vapour is very poisonous. Insoluble in water, readily soluble in alcohol and ether; takes fire on gentle heating in air. With iodine it yields mercury methyl iodide, $HgCH_3I$, and the same compound is obtained when methyl iodide and mercury are exposed to sunlight. Mercury methyl is obtained by the action of sodium amalgam on methyl iodide in presence of ethyl acetate, or when mercury methyl iodide is distilled with caustic potash. "Sublamin" is a compound of ethylene diamine with mercuric sulphate,

$$\{C_2H_4(NH_2)_2\}_3\{HgSO_4\}_2,$$

which is used like corrosive sublimate as an antiseptic. *Mercury Ammonium Compounds:*—Compounds in which divalent mercury replaces the hydrogen of the ammonium group, $(NH_4)'$. DIMERCURAMMONIUM OXIDE, $(NHg_2)_2O$, is a dark brown explosive powder, obtained by the action of liquid ammonia on mercuric oxide. The hydroxide corresponding to this oxide, NHg_2OH, is a pale brown powder obtained by heating its hydrate, $NHg_2OH . 2H_2O$, at 80° to 85°; the hydrate is formed as a pale yellow powder when mercuric oxide is warmed with dilute ammonia. The salts of this oxide are formed from it by the action of acids. Of these salts the following are important: The HYDRATE OF DIMERCURAMMONIUM IODIDE, $NHg_2I . H_2O$. This is the substance formed when Nessler's reagent is used to test for ammonia, $2HgI_2 + 3KOH + NH_3 = NHg_2I . H_2O + 3KI + 2H_2O$. WHITE PRECIPITATE (INFUSIBLE), $NH_4Cl . NHg_2Cl$: A double salt of ammonium chloride and dimercurammonium chloride, called infusible because it decomposes without melting, when heated, into calomel, ammonia, and nitrogen. It is formed by adding ammonia to a solution of corrosive sublimate. It is used in medicine. WHITE PRECIPITATE (FUSIBLE) is probably $NHg_2Cl . 3NH_4Cl$, and is formed by boiling the last compound with a solution of ammonium chloride.—W. H. H.

Mercury Gauge. An instrument for measuring the pressure of a liquid or gas by observation of the height of a column of mercury necessary to balance the pressure under consideration. This device is much used in physical measurements; it was at one time used in engineering to measure steam pressure; its chief use in engineering is now for testing the graduations of Bourdon and similar pressure gauges.

Mercury Vapour Lamp, Hewitt's (*Elect.*) A long vacuum tube containing a quantity of mercury at the lower end, at which is the negative pole. The lamp will work with the ordinary voltage of an electric supply, but requires a spark from an induction coil to start it. The light is very unpleasant in

colour, but extremely economical. It is said to require from one third to one half of a watt per spherical candle power (*q.v.*), whereas the ordinary incandescent electric lamp requires four watts. The lamp can be used with any voltage from 100 to 1000, and with a current up to 100 ampères, either direct or alternating. With the latter, however, the difficulties of starting are greater than in the case of a direct current; when started, the current flows in one direction only.

Mericarp (*Botany*). The term applied to the two parts (each containing one seed) of the fruit of the *Umbelliferæ*, *Labiatæ*, and other orders. The caraway "seed" is a mericarp.

Meridian. (1) Midday or noon; figuratively the culmination. (2) One of the innumerable imaginary lines or circles on the surface of the earth passing through the North and South Poles and through other given places, and employed for denoting the longitude of places. The FIRST MERIDIAN is that from which all others to the eastward or westward are counted, usually the meridian of Greenwich.

—— (*Astron.*) A great circle passing through the celestial poles, zenith, and nadir (*q.v.*) It is therefore at right angles to the horizon.

Meridian Circle (*Astron.*) A transit instrument fitted with circles by means of which the north polar distances or declinations of stars can be determined.

Meridian, Magnetic (*Phys.*) The vertical plane in which are situate the two points on the horizon towards which the magnetic needle points.

Meridian Mark (*Astron.*) If a transit instrument is used for making long series of observations, a permanent meridian mark is made to assist in determining the azimuth constant.

Meridian, Terrestrial. A great circle (*q.v.*) on the earth, passing through the terrestrial poles. It crosses the equator at right angles.

Merino (*Textile Manufac.*) Fine worsted dress fabric.

Merions (*Architect.*) *See* BATTLEMENT.

Mermaid (*Her.*) This mythical being is used as a charge or badge in heraldry; example, the Berkeley brass, 1392.

Merohedrism (*Min.*) A term including both the types of development of crystal faces known as HEMIHEDRISM and TETARTOHEDRISM (*q.v.*)

Meros (*Architect.*) The flat space between the channels or glyphs of a triglyph. It is also known as a FEMUR. *See* TRIGLYPH

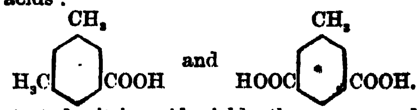
Mesentery (*Zool.*) The membrane which surrounds and supports the intestines of an animal.

Mesh. The openings in a net, sieve, or woven fabric; also a general term for similar openings in other objects.

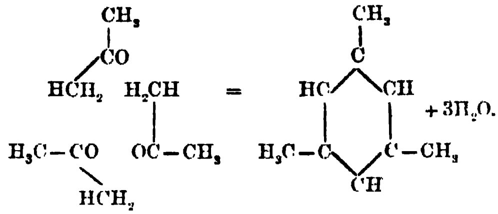
—— (*Lace Manufac.*) A mesh of net is one complete hole.

Mesh Connection *or* **Grouping** (*Elect. Eng.*) An arrangement of the coils of a three phase motor in the form of the Greek letter Δ.

Mesitylene (*Chem.*),  (*Symmetrical trimethylbenzene.*) A colourless liquid smelling like benzene; boils at 164°. Halogens in the dark replace the hydrogen of the nucleus; at the boiling point they enter the side chains. Boiled with dilute nitric acid, it is oxidised to mesitylenic and uvitic acids:



Concentrated nitric acid yields the mono- and di-nitro derivative; fuming nitric and sulphuric acids yield the tri-nitro derivative. Mesitylene occurs in coal tar; it can be prepared by allowing acetone to stand with excess of sulphuric acid and distilling the product. This method of formation is a proof of its constitution.



Mesityl Oxide (*Chem.*) $(CH_3)_2.C:CH.CO.CH_3$. A colourless liquid smelling like peppermint, boils at 132°; unites with bromine to form a dibromide; with ammonia to form diacetoxamine, $(CH_3)_2CNH_2.CH_2CO.CH_3$; with hydrazine to form 3:5:5-tri-methyl pyrazoline, 
Heated with dilute sulphuric acid it yields acetone. It is prepared by passing hydrochloric acid gas into cold acetone, allowing to stand, washing with caustic soda, distilling in steam, and fractionally distilling the product to separate phorone (*q.v.*)

Mesolite (*Min.*) A hydrous calcium aluminium sodium silicate of complex formula. Triclinic, occurring in delicate capillary crystals. It is one of the ZEOLITES (*q.v.*) From vapour cavities in volcanic rocks near Edinburgh, in Skye, Antrim, etc.

Mesotartaric Acid (*Chem.*) *See* TARTARIC ACID.

Mesozoic (*Geol.*) One of the larger subdivisions of the geological time scale. It embraces all the rocks below the base of the Eocene strata down to that of the Trias or Upper New Red. When the fossils of the Dyas or Lower New Red are better understood the base of the Mesozoic group of rocks will include also that subdivision of the New Red. The name refers to the fact that the forms of life represented in the Mesozoic rocks are intermediate in character between the Palæozoic times and those of the present day.

Mesto (*Music*). Sadly.

Metacentre (*Hydrostatics*). If a vertical line be drawn through the centre of gravity of a floating body when at rest, it will pass through the centre of gravity of the liquid which is displaced by the body. If now the latter be moved from its position of equilibrium, the centre of gravity of the displaced liquid will no longer be in this line, and a new vertical line drawn through it will intersect the former line in a point which is termed the META-

CENTRE. If the metacentre be above the centre of gravity of the body, the latter is in stable equilibrium, while if it be below the centre of gravity the body is in unstable equilibrium.

Meta Compounds (*Chem.*) The prefix "meta" is used in three distinct senses in chemical nomenclature. (1) There is a series of acids and salts distinguished by this prefix. The meta acids may be regarded as derived by the union of one molecule of the acid oxide with one molecule of water, and the meta salts are derived from these acids. Examples: Metaboric acid, $B_2O_3 + H_2O = 2HBO_2$. Metarsenites (acid unknown), $As_2O_3 + K_2O = 2KAsO_2$. Metasilicic acid, $SiO_2 + H_2O = H_2SiO_3$. Metaphosphoric acid, $P_2O_5 + H_2O = H_2P_2O_6$. Metaperiodates, $I_2O_7 + K_2O = 2KIO_4$. (2) There are many substances which undergo polymerisation, and the prefix meta is applied to the polymer of unknown molecular weight or whose molecular weight was unknown when the name was given. Examples:

Metastannic acid, $H_{10}Sn_5O_{15}$.	Polymer of stannic acid, H_2SnO_3.
Metaldehyde, $(C_2H_4O)x$.	Polymer of aldehyde, C_2H_4O.
Metastyrol, $(C_8H_8)x$.	Polymer of styrol, C_8H_8.

(3) The prefix is given to benzene derivatives when the substituents have replaced hydrogen atoms which are next but one to each other. For example *see* BENZENE.

Metal (*Glass Manufac.*) The name given to molten glass.

—— (*Plumb.*) In plumbers' work this term signifies solder.

—— *See* METALLURGY *and* METALS.

Metal Arches (*Civil Eng.*) Arches built up of iron or steel girders and lattice work, instead of solid stone blocks. As the members of such a structure can withstand tension as well as pressure, the structure can be modified to suit a greater variety of circumstances than stone bridges can.

Metaldehyde (*Chem.*) *See* ACETALDEHYDE.

Metal Furniture (*Typog.*) Furniture composed of an alloy. It gives truer register and is more economical than wooden furniture, and is now used extensively. *See* FURNITURE (*Typog.*)

Metal Leaf (*Dec.*) A term used for imitation leaf gold consisting of an alloy beaten out and sold in the same size sheets as gold leaf (*q.v.*) The term is also employed to include silver leaf, aluminium leaf, nickel leaf, and other leaf metal employed by gilders on glass and for decorative purposes generally.

Metallic Circuit (*Elect. Eng.*) A circuit composed entirely of metal conductors (*e.g.* wires) as distinguished from one in which the return path of the current is through the earth.

Metalliferous Veins (*Geol.*) Clefts or fissures in the Earth's crust which contain one or more of the ores of the metals, usually in association with other mineral substances of a non-metalliferous character, such as Quartz, Calcite, Barytes, and Fluor. The vein fissures are generally coincident with faults or lines of fracture, which appear to have formed the channels by which thermal or other waters containing these substances in solution have risen in the direction of the surface, and have left these substances when their depositing temperatures have been reached. The ores are most commonly compounds of the metals with Sulphur; but Arsenic, Antimony, or Bismuth may also be present. In rarer cases the metals may be combined with Tellurium. Near the surface of metalliferous veins carbonates and various oxygenated compounds usually occur. *See also* MINING.

Metallisation (*Elect. Eng.*) Covering a non-conductor with a film or coating of metal in order to impart electrical conductivity. Often used in electroplating non-metallic objects.

Metallography. The examination of prepared surfaces of metals under the microscope is of comparatively recent growth, for the first work in this direction was done by Dr. Sorby, of Sheffield, about 1864. It closely resembles the microscopic study of rocks, and was probably suggested by the examination of metallic meteorites in a similar manner. Rock sections are usually thin enough to be examined by transmitted light; but metallic sections are opaque, and reflected light must be used for their examination. A small piece of the metallic body is so cut as to form a fair sample of the whole. This is ground and polished to a flat surface, free from microscopic scratches. The structure is then brought out by immersing the surface in an etching liquid, by heating in air, or by a final polishing on a soft bed. The object of this treatment is to bring about a differential attack upon the structural constituents of the surface, and so render them visible under the microscope. Many such constituents are so identified in iron and steel, and in alloys of copper, tin, lead, zinc, antimony, etc. Several constituents of steel, in the different states of the metal brought about by heat treatment, combined with sudden and slow cooling, have been recognised. The principal of these are ferrite, pearlite, sorbite, and troostite. The different constituents, when viewed under the microscope, present very characteristic appearances; and the sections can be preserved for future examination by a thin coat of transparent varnish, or a photomicrograph can be taken and a permanent record thus obtained. The magnifications used are from 25 to 2,000 diameters. By work of this kind the crystalline character of metals in their normal state has been clearly brought out, and much information about the effects of mechanical stresses, of annealing, and of impurities upon the structure and properties of metals has been obtained. The similarity of quenched steel to a solid solution has been proved, and the assimilation of solid solutions to liquid solutions indicated. The subject is gradually growing in importance, and among its many workers are to be found the names of such men as Martens, Osmond, Stead, Roberts-Austen, Charpy, Heycock, and Neville.

Metalloid (*Chem.*) A name given to a few elements which may be regarded as sharing the properties of a metal and a non-metal. Thus antimony forms a gaseous hydride, SbH_3; two acid oxides, Sb_2O_3 and Sb_2O_5, and resembles the non-metals in these respects; but it forms a chloride which behaves in most respects like a metallic chloride, and it forms a sulphate which no non-metal does, yet it forms no carbonate, phosphate, or nitrate, as most metals do. Tellurium is another metalloid. Arsenic is regarded by some as a metalloid, but chemically its behaviour is entirely non-metallic.

Metallurgy. Dr. Percy, who did so much for the systematic study of metallurgy in this country, defined it as "the art of extracting metals from their ores, and adapting them to the various purposes of manufacture." That the art was practised in very

early times is indicated by the references to metals and their uses in the oldest written records of the world's history. In fact, the ancient Egyptians and Hebrews were so skilled in the working of metals that the craft must have been in existence before the dawn of history. Metals are rarely found in the metallic state, but are usually combined with oxygen, sulphur, carbon, etc. These compounds are always mixed with more or less earthy matter, or "gangue," and together with it form the ores of the metals. Gold occurs in the metallic state in its ores. There are two main processes used in the smelting, or fire treatment, of ores for the extraction of their metals. These are *roasting* and *melting*. In the first, the material is heated in contact with air to a temperature below its fusing point, so that it remains solid during the operation. In the second, the material is melted either by itself or mixed with other materials necessary for the complete operation. This work is done in furnaces of various kinds, but belonging to two main types: (*a*) reverberatory furnaces, in which material to be heated is placed on a separate bed; and (*b*) shaft furnaces, in which the fuel for generating the heat is mixed with the materials to be heated. In addition to this heat treatment, some ores have to undergo the mechanical processes of crushing, grinding, and washing for the partial removal of earthy matter. Also some ores cannot be dealt with economically by the heat method, and their metals are extracted by the use of liquid agents; others, again, are best treated by a combination of the two methods. The extraction of iron from its ores was practised among the hill tribes of India at least three thousand years ago, and the ancient method is still in use there. Iron ore and charcoal are put into a small blast furnace, worked with goatskin bellows, and several hours are occupied in producing only as much iron as a man can carry in one hand. For a very long period little or no progress in iron smelting was made; but as the process migrated Westwards, the apparatus increased in size, and the output became larger. The next step was the extraction of the metal as cast iron, and the conversion of this material into wrought iron and steel by a separate process. This was followed by a considerable increase in the size of the furnaces. In 1806 a blast furnace in Staffordshire was making pig iron at the rate of 30 tons per week. Then came the introduction of the hot blast (1828), still larger furnaces, and a much increased output; but with the modern puddling process to cope with it. At the present time the Americans are leading in blast furnace practice. Working with a furnace 80 ft. high and 20 ft. in diameter, an output of 3,000 tons of pig iron per week is often obtained. The magnitude of this development will be understood when it is stated that about 8,000 tons of ore, flux, and fuel must be tipped into the top of the furnace, and 15,000 tons of air blown in at the bottom to produce this result. The accessory apparatus, such as blowing engines, hot blast stoves, and charging gear are large in proportion. The introduction of the Bessemer process (1855) for the conversion of molten pig iron into ingot iron and steel by blowing a strong blast of air through it caused a revolution in the iron and steel industry. The invention of the basic lining for the Bessemer vessel caused a further increase in its usefulness. With this apparatus 10 tons of pig iron can be converted into ingot iron or mild steel in twenty minutes. But this process has been largely displaced by the introduction of the Siemens open hearth, in which large quantities of similar metal are now being made. This furnace, which is of the reverberatory type, is worked with gaseous fuel, and its temperature is further increased by the use of the principle of regeneration also introduced by Siemens. The first furnaces in general use were of about 10 tons' capacity, and the development of the process is mostly in the direction of larger furnaces. Fixed furnaces of 40 and 50 tons' capacity are now common, and tilting furnaces of the Wellman type of 200 tons' capacity are coming into use. It is in such furnaces that the Talbot steel making process is being put to the test of practical experience. On the other hand, the Bertrand-Thiel, or duplex hearth, process is carried out in fixed hearths, and is in successful, though limited, operation. Another development is in the use of the combustible part of the waste gas from the blast furnace, which is produced in enormous quantities, for working gas-engines, instead of for raising steam. This has made greater headway in Germany than in this country. The magnetic separation of finely divided ore, by which the iron compound is separated from the earthy matter, is now largely practised. Much attention has been given of late years to the production of sound ingots. In the latest modification Hamet, of St. Etienne, introduces the pressure at the bottom of the mould instead of at the top, and with considerable success. Electrical appliances are coming into general use; and electric smelting of iron and steel is making some headway where water power is cheap. In the metallurgy of copper considerable advance has been made of late years. The Welsh process, which was carried out entirely in reverberatory furnaces, was the principal method of extraction when Swansea was the chief copper smelting district of the world. Now many modifications have been introduced; the water jacketed blast furnace for the production of coarse mattes, and the Bessemer converter for fine mattes and coarse copper, are largely used. Even the refining of copper is being carried on electrolytically when gold, silver, or nickel is present in the crude metal. The furnaces for roasting pyritic ores and mattes have been much improved, and mechanical furnaces are taking the place of hand worked ones. The White-Howell, in which the finely divided ore is fed in at one end of a revolving cylinder, through which hot gases and air are passing and delivered at the other end, is an illustration of this change. The winning of gold from its ores has been helped by the introduction of the cyanide method of extraction. This was first used in South Africa, but has now found its way to America and Australia. It depends upon the fact that a weak solution of potassium cyanide will dissolve finely divided gold, and that gold can be precipitated from the solution by zinc. It is largely used in the treatment of slimes which have already been through the amalgamation process. At the Homestake Mine, Dacotah, 1,250 tons are treated daily. The gold reduced from the solution by the zinc is collected in a filter press, and allowed to accumulate until a cake about a ton in weight, and worth £10,000, is obtained; this is then refined by cupellation. Seventy-five per cent. of the assay value of the slimes is recovered at a cost of 1*s*. 6*d*. per ton of slimes. The Indian gold industry has benefited by its introduction, and it has solved the difficulty of dealing with telluride ores of gold in Western Australia. The extraction of other metals has been considerably influenced by modern improvements in furnace construction and working. This is so in the case of zinc, mercury, tin, etc., and the old wet

method of nickel extraction has disappeared. The use of the blast furnace in dealing with complex lead ores containing silver has considerably reduced the price of the latter metal. Ancient metallurgy was the father of chemistry, but modern metallurgy owes much to the exact processes of modern chemistry.—J. H. S. *See also* MINING.

Metal Patterns. Patterns made of brass, tin, lead, or (more commonly) of iron. *See* IRON PATTERN.

Metal, Road (*Civil Eng.*) *See* ROAD METAL.

Metal Rule (*Typog.*) A general expression for the rule by means of which plain, dotted, wavy, or other lines are produced in printing—em rules or dashes, thus –, —, ——.

Metals. Solid elements, with the single exception of mercury, which is a liquid, which (*a*) form basic oxides, (*b*) form chlorides which are in most cases not decomposed by water, and in the few cases in which they are decomposed by water give basic chlorides; (*c*) either form no compound with hydrogen or, when they do, give a solid compound, while all non-metals form at least one hydrogen compound which is gaseous. Any typical metal will conform to all these requirements; but in one or two cases the requirements are not completely conformed to, as, for instance, in the case of antimony, which forms a gaseous hydride, but conforms in other respects: antimony may be called a metalloid (*q.v.*) Besides the chemical distinctions just mentioned, there are certain physical properties which distinguish the metals as a class from the non-metals as a class; but if these are applied to particular cases they often break down. For example, the density of the metals as a class is higher than that of the non-metals as a class; but the metal lithium has a density of 0·6, while the non-metal iodine has a density 5·0. The physical properties referred to are density, malleability, ductility, electrical and thermal conductivity. As a class the metals possess these properties in a higher degree than the non-metals as a class; but the metals show great differences among themselves in these properties. Lithium, the lightest metal, has a density of 0·6, while osmium, the heaviest metal, has a density of 22·5. Pressure increases the density up to 10,000 atmospheres, and above this up to 150,000 atmospheres diminishes it—the explanation of this surprising result being that a metal contains solid and liquid molecules the former of which are incompressible, but at excessive pressure change to the latter and increase in volume in doing so. In malleability metals differ enormously, gold, silver, and copper being the most malleable; gold, silver, and platinum the most ductile; while bismuth is neither malleable nor ductile. In conductivity, both electrical and thermal, similar wide differences exist; thus, the former value for copper being 100, silver, the best conductor, is 105, and mercury is 1·6; the latter value for silver being 100, copper is 73·6, and mercury is 1·3. The melting points of the metals also vary greatly: mercury melts at −39·4°, silver at 961°, copper at 1080°, platinum at about 1780°, chromium about 2000°, while osmium is practically infusible. Many metals are transparent to light in thin films: gold leaf transmits green light; mercury, blue light; silver, blue light. Most metals appear to have monatomic molecules (*q.v.*); this has been ascertained by the lowering of the freezing points of solutions of the metals in tin.

Metals (*Civil Eng.*) The rails of a railway.

—— (*Her.*) There are two metals used in heraldry —gold and silver blazoned *or* and *argent*. *See under* HERALDRY.

Metal Spinning (*Eng., etc.*) Many circular objects may be formed out of sheet metal by means of a process termed spinning. A flat sheet of metal is cut approximately to size, and mounted on a chuck whose cross-section follows the profile of the object to be formed. The chuck is set in rotation in a lathe, and a smooth blunt-ended tool is pressed against the metal, which is gradually caused to conform to the outline of the mould formed by the chuck. The process can be applied to almost any malleable metal, and is frequently used in forming circular bowls, dishes, etc., of pewter, Britannia metal, copper, and brass.

Metamerism (*Chem.*) *See* ISOMERISM.

Metamorphic Rocks (*Geol.*) Sedimentary or else eruptive rocks which have undergone changes within the Earth's crust, by which their original character has been more or less altered. This may arise through the prolonged action of heated waters without any accompanying effect of a mechanical nature (thermometamorphism). Of this nature are many marbles and quartzites, and all kinds of hornfels. It may be due to causes of a dynamical kind, as in the case of the conversion of sediments into Muscovite Schist; or, lastly, it may arise simply through the chemical action of subterranean waters at a low temperature.

Metamorphism (*Geol.*) A general term used by geologists in connection with rocks of any kind that have undergone changes since their formation which have altered their general aspect. It is usual to recognise three types: (1) The changes induced in rocks by the prolonged action of heat in the presence of water. This is distinguished as thermometamorphism. (2) The effects arising from movements within the Earth's crust, especially from those connected with important changes of level at the surface. These are referred to as dynamic metamorphism. (3) The effects of the prolonged action of underground waters. The last is known as hydrometamorphism.

Metaphosphates (*Chem.*) Salts of metaphosphoric acid. *See* PHOSPHORUS COMPOUNDS.

Meteor (*Astron.*) A small body which becomes incandescent in passing into the Earth's atmosphere, and is burnt up before it reaches the Earth's surface. There are numerous showers of meteors, the more important being those that occur in August and November each year.

Meteorites (*Astron.*) Stony or metallic bodies of various sizes which fall on the Earth's surface from outer space. In passing through the air they become fusible, and sometimes burst with a loud explosion. They are usually classed, according to their composition, as: (1) Stony meteorites or aërolites, which are closely related to some of the ultrabasic eruptive rocks. (2) Siderites, which consist largely of alloys of iron and nickel.

Meteoritic Hypothesis (*Astron.*) An hypothesis which suggests that all the heavenly bodies are either meteoric swarms, more or less condensed, or the final products of such condensation.

Meteorograph (*Meteorol.*) An instrument generally attached to kites for obtaining the combined records of the thermometer, barometer, anemometer, and relative humidity.

Meteorology. Meteorology is the science which treats of the condition of the atmosphere surrounding our earth and the causes which give rise to the manifold variations of temperature, etc. The subject may be divided into WEATHER and CLIMATE. WEATHER may be regarded as one phase in the succession of phenomena whose complete cycle, recurring with more or less uniformity every year (*see below*), constitutes the climate of any place. CLIMATE is, therefore, the sum total of the weather, and gives us an idea of the *average* conditions of the atmosphere on different parts of the earth's surface. The earth with its surrounding envelope of air being a satellite of the sun, a body relatively very hot and of immense size, it is only natural that this central orb should be the all-dominating factor in terrestrial atmospheric changes and movements. This envelope is heated indirectly by the solar rays, the earth being warmed first and then parting with its heat to the air in contact with it. A circulation is thus set up, the warm air rising, and its place being filled up by the inflow of cooler air. This ascent of warm air reduces the atmospheric pressure at the locality in which it occurs, and thus a cyclonic region is initiated. Low pressures therefore are associated with ascending air currents. Since the air in these ascending currents cools as it reaches higher regions of the atmosphere, it must necessarily descend again to the earth. Regions where these descents occur are localities of high pressure (anticyclonic areas). The earth being unequally heated by the solar rays, the equatorial regions receiving more heat than the poles, there is a tendency for an interchange of air between these localities. What is the exact manner of this interchange is a question as yet under investigation; but it is shown to be incorrect to say that "polar" and "equatorial" currents, as usually defined, occur. Nevertheless, the earth, with the cold regions at the poles and the highly heated equator, may be considered as a huge condenser. Two facts which tend to complicate the atmospheric circulation are: (*a*) That land surface is more easily heated and more quickly cooled than water surface; and (*b*) that the distribution of land and water is very unequal, the northern hemisphere having by far the greater predominance of land. Again, the earth is not a stationary body relative to the sun, but moves, revolving round it once a year, and at the same time spinning on its axis in a period of a day. The first result of this latter motion is that the general circulation towards and away from the equator does not take place in a north or south direction, but the direction of movement is deviated to the right of the original direction. Again, since only one-half of the earth can be turned towards the sun at any one moment, the other half being in darkness and shielded from the heat rays of the sun, an unequal heating of the atmosphere as a whole is set up. This results in the "diurnal variations" of the meteorological elements, such as pressure, temperature, etc. These elements have also an annual variation, due to the revolution of the earth round the sun. In consequence of the inclination of the earth's axis to the plane of the ecliptic—*i.e.* the plane in which the earth moves—sometimes the northern hemisphere and sometimes the southern hemisphere is more exposed to the solar rays. This is the cause of the variations known as "seasonal changes." In consequence of these two periodic movements of the earth, and the resulting variations in the intensity and direction of the air currents, we have changes of WEATHER. The greater the distance from the equator the more complex do these changes become, owing to the interlacing currents producing rapidly moving cyclonic and anticyclonic areas. Now, if the sun gave out the same quantity of heat each year, more would probably be known about the laws of such changes. Although direct measurements of the quantity of heat radiated do not indicate solar variations of heat, there are periodic changes in solar phenomena, such as spots, prominences, and coronal streamers, which show great disturbances in the solar atmosphere. These disturbances are periodic in their nature, so far as can at present be determined, and have periods of about four, eleven, and thirty-five years. There is thus reason to believe that the sun does change its temperature, and such variations should have its effect on the terrestrial atmospheric circulation. WEATHER, therefore, will be subject to continual changes, and so will the CLIMATE of any region. That all countries are subject to series of wet and dry years, with their attendant disastrous floods and droughts respectively, is a fact well known, and it is the aim of METEOROLOGY to investigate, and possibly ultimately discover, the laws by which these variations are governed.—W. J. S. L.

Meter (*Build.*) An apparatus for measuring the volume of gas or water supplied to a building, etc.

—— (*Elect. Eng.*) A device for measuring the amount of energy—usually in WATT HOURS (*q.v.*)—supplied. A meter usually contains mechanism actuated or controlled by the current; this mechanism registers the supply by means of dials. In most cases, as the voltage is constant, only the number of ampère hours is recorded, one ampère hour being the quantity of electricity which is transferred by a current of one ampère flowing for one hour. There are very many types of meter; the following may be taken as examples. The ARON METER contains two trains of clockwork, each governed by a pendulum. One pendulum swings under the action of gravity only; the other carries a permanent magnet as a bob. Underneath this magnet a solenoid is fixed, through which the current passes. An additional controlling force is therefore experienced by the second pendulum, which causes it to swing quicker than the first. The number of beats which the second pendulum gains in a given time depends upon the strength of the current (other things being equal); by means of suitable mechanism this number is registered, and the number of ampère hours read off on dials. The EDISON METER depends upon the principle of electrolysis (*q.v.*), and registers the quantity of current which has passed by means of the decomposition of a solution of zinc sulphate with zinc electrodes. The loss in weight of the anode should equal the gain in weight of the cathode, and each is proportional to the total quantity of electricity which has flowed through the electrolytic cell. The SHALLENBERGER and ELIHU THOMPSON METERS are types in which the mechanism is rotated by the current at a rate which is proportional to the current whose strength is to be recorded. The former is adapted for the measurement of alternating currents at constant voltage; the latter can be used on either alternating or direct current circuits, and gives the number of watt hours directly, whether the voltage vary or not.

Methane (*Chem.*) CH_4. *Also called* **Marsh Gas, Light Carburetted Hydrogen,** *and, by coal miners,* **Firedamp.** A colourless, odourless gas; boils at $-156°$, solidifies at $-184°$. It is a light gas, very

sparingly soluble in water. It burns in air with a feebly luminous flame to carbon dioxide and water, $CH_4 + 2O_2 = CO_2 + 2H_2O$. A mixture of methane with twice its volume of oxygen—the proportions required by the above equation—or ten times its volume of air, explodes violently when ignited. When slowly burned with insufficient oxygen (two volumes marsh gas to one volume oxygen) it forms formaldehyde, carbon monoxide, carbon dioxide, and steam.

$$\begin{array}{c}H\\|\\H-C-H\\|\\H\end{array} + O_2 = \begin{array}{c}H\\|\\H-C=O\end{array} + H_2O, \begin{array}{c}H\\|\\H-C=O\end{array} + O_2 = CO_2 + H_2O$$

$$2\begin{array}{c}H\\|\\H-C=O\end{array} + O_2 = 2CO + 2H_2O$$

Chlorine in bright sunlight decomposes it, giving carbon and hydrochloric acid. But when the action is slower substitution occurs, giving methyl chloride, CH_3Cl; methylene chloride, CH_2Cl_2; chloroform, $CHCl_3$; and carbon tetrachloride, CCl_4. It occurs when vegetable matter decomposes in contact with water, so that it arises in bubbles from stagnant pools, and it is found in coal. Its presence in coal mines is sometimes the cause of explosions. It also occurs in the gases from oil wells. Methane is synthesised by passing carbon monoxide or dioxide and hydrogen over finely divided nickel at 300°. Ordinarily it is prepared by heating a mixture of sodium acetate and soda lime, $\begin{array}{c}CH_3\\|\\COONa\end{array} + HONa = CH_4 + CO(ONa)_2$.

Very pure methane is obtained by the action of zinc coated with copper on a mixture of methyl iodide and methyl alcohol,

$$CH_3I + CH_3OH + Zn = CH_4 + Zn\left<\begin{array}{l}CH_3\\I\end{array}\right.;$$

but the gas so prepared must be passed through a tube immersed in a powerful freezing mixture to remove vapour of methyl iodide.

Methoxides (*Chem.*) Compounds derived from methyl alcohol by the replacement of the hydroxyl hydrogen by metals; *e.g.* sodium evolves hydrogen when it is brought into methyl alcohol, and forms sodium methoxide, $CH_3OH + Na = CH_3ONa + H$. This is the most important methoxide; it is a white crystalline solid, soluble in methyl alcohol, and easily decomposed by water, $CH_3ONa + H_2O = CH_3OH + NaOH$.

Methoxy (*Chem.*) The name given to the group CH_3O-. This group has no independent existence, but this name for the group enters largely into chemical nomenclature; *e.g.* several alkaloids contain methoxy groups (codeine, *see under* MORPHINE; quinine, *see under* CINCHONINE). The methyl group in methoxy compounds is replaced by hydrogen by the action of hydriodic acid. The hydroxy group (—OH) in a phenol is converted into the methoxy group by the action of methyl iodide and sodium ethoxide. *See under* MORPHINE.

Methven Screen. An opaque screen containing a narrow slot, placed in front of a standard gas burner; the size of the slot is so adjusted that the light transmitted shall be equal to that of two standard sperm candles, when the gas flame is 3 in. high. Its value depends upon the fact that the luminosity is proportional to the height of the flame rather than the quality of the gas, within very wide limits. It is used as a standard light in photometric work.

Methyl (*Chem.*) The name given to the group CH_3-. This group has no independent existence, but this name for the group enters largely into chemical nomenclature; *e.g.* CH_3Cl is called methyl chloride; $C_6H_5NHCH_3$ is called methyl aniline, because it may be regarded as aniline, $C_6H_5NH_2$, in which one atom of hydrogen in the NH_2 group has been replaced by the methyl group.

Methylal (*Chem.*), $CH_2\left<\begin{array}{l}OCH_3\\OCH_3\end{array}\right.$. Pleasant smelling liquid; boils at 42°; soluble in water. Formed by oxidation of methyl alcohol with manganese dioxide and dilute sulphuric acid.

Methyl Alcohol (*Chem.*), CH_3OH. (The crude alcohol is called wood spirit and wood naphtha.) A colourless liquid; smells like ethyl alcohol; boils at 66°; soluble in water: burns with blue flame to carbon dioxide and water. Its chemical reactions are like those of ethyl alcohol. With sodium it gives sodium methoxide, CH_3ONa; with the chloride of phosphorus, methyl chloride, $3CH_3OH + PCl_3 = 3CH_3Cl + H_3PO_3$; it forms a crystalline solid with calcium chloride, $CaCl_2 4CH_3OH$; on gentle oxidation it forms formaldehyde (*q.v.*); with acids usually in presence of a dehydrating agent it forms esters, *e.g.* $CH_3OH + HCl = CH_3Cl + H_2O$. It occurs combined with salicylic acid in oil of wintergreen, and can be obtained from this by boiling in a flask with reflux condenser with caustic soda solution, then distilling the product. Only methyl alcohol and water distil over

$$C_6H_4\left<\begin{array}{l}OH\\COOCH_3\end{array}\right. + NaOH = \underset{\text{Sodium salicylate.}}{C_6H_4\left<\begin{array}{l}OH\\COO\ Na\end{array}\right.} + CH_3OH$$

On the large scale it is obtained from the watery portion of the distillate from the distillation of wood in closed vessels. This watery portion is called pyroligneous acid. About a tenth is distilled over, and the distillate is mixed with slaked lime and redistilled. This removes acetic and other acids. It is now distilled from a little sulphuric acid: this removes bases. This distillate is stood over quicklime and again distilled—removal of water. This product is crude wood spirit; it contains acetone and other impurities. Calcium chloride is now added to form the crystalline compound mentioned above, which is filtered off and pressed, treated with water, and distilled; methyl alcohol and water pass over. The alcohol is dehydrated over quicklime as before.

Methylamine (*Chem.*), CH_3NH_2. Gas, colourless; smells like ammonia and fish at the same time; boils at −6°; extremely soluble in water (1,150 volumes in 1 volume of water at 12·5°); readily burns in air with a yellow flame, forming carbon dioxide, water, and nitrogen. It is a powerful base, forming salts with acids, just as ammonia does, and its aqueous solution gives precipitates of the hydroxide with solutions of metallic salts, also like ammonia does; but with nitrous acid it yields methyl alcohol.

$$CH_3NH_2 + ON.OH = CH_3OH + N_2 + H_2O$$
$$NH_3 + ON.OH = H_2O + N_2 + H_2O$$

With methyl iodide it forms dimethylamine hydriodide, then trimethylamine hydriodide, then tetramethylammonium iodide. It unites with ethyl oxalate to form dimethyloxamide. *See* TRIMETHYLAMINE. It occurs in herring brine, in pyroligneous acid (*see* METHYL ALCOHOL), in the plant Dog's Mercury (*Mercurialis perennis*). It is best obtained from acetamide by dissolving in

bromine, adding 10 per cent. caustic potash solution till yellow, and distilling the product with 20 per cent. caustic potash. The distillate must be received in hydrochloric acid. Some ammonia comes over with the methylamine. To separate the two hydrochlorides evaporate to dryness on a water bath, and treat with absolute alcohol, when methylamine hydrochloride alone dissolves; filter and evaporate; the base may be set free by caustic soda. It is also produced by the reduction of hydrocyanic acid with zinc and sulphuric acid, by the reduction of nitromethane with iron fillings and acetic acid, by distilling glycocoll (*q.v.*) with baryta.

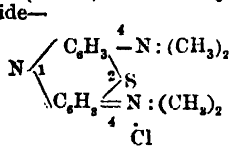
Methylated Spirit (*Chem.*) A mixture of 90 per cent. raw spirit of wine (crude ethyl alcohol) and 10 per cent. wood spirit (crude methyl alcohol), to which some paraffin oil has been added. This concoction can be used for many technical and chemical processes, instead of pure alcohol, and as it is not drinkable it is sold free of duty. It is used as a solvent, for burning, and for the manufacture of "methylated" ether and "methylated" chloroform.

Methylates (*Chem.*) *See* METHOXIDES.

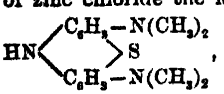
Methyl Chloride, Bromide, *and* **Iodide** (*Chem.*), CH_3Cl, CH_3Br, and CH_3I. The first two are gases which boil at $-24°$ and $4·5°$ respectively; the third, is a liquid which boils at 43°. In properties, reactions, and preparation they resemble the corresponding ethyl compounds. *See these.* The chloride is used in medicine as a local anæsthetic, and the iodide is an important reagent in organic chemistry, just as ethyl iodide is.

Methylene (*Chem.*) The name given to the group $\overset{|}{\underset{|}{CH_2}}$, which has not an independent existence. Examples of methylene derivatives are methylene iodide, CH_2I_2; hexamethylene, $CH_2\left<\begin{smallmatrix}CH_2-CH_2\\CH_2-CH_2\end{smallmatrix}\right>CH_2$, etc. Methylene iodide is a heavy colourless liquid (specific gravity, 3·34), obtained by reduction of iodoform with hydriodic acid.

Methylene Blue (*Chem.*) Tetramethylamidophenthiazimium chloride—



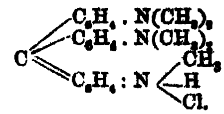
Dark blue powder, soluble in water and alcohol; dyes cotton mordanted with tannin a blue which is fast to light. Used in medicine for malaria, etc.; it colours the urine and fæces blue. It is obtained by oxidation of dimethylparaphenylenediamine in presence of sodium thiosulphate and further oxidation of the product by chromic acid in presence of dimethylaniline. On now boiling with a solution of zinc chloride the leuco-base is obtained



, which on oxidation yields the dye. The commercial dye is the zinc double salt $2(C_{16}H_{18}N_3SCl) . ZnCl_2 . H_2O$. *See* DYES AND DYEING.

Methyl Orange (*Chem.*) (*Also called* **Orange III., Helianthine, Tropæoline D.**) It is the sodium salt of paradimethylamidobenzene sulphonic acid (the free acid is sometimes called Helianthine). A yellowish red powder, soluble in water, giving a yellow solution when diluted. With acids the solution turns pink; on neutralisation of the solution the yellow colour is restored. *See* INDICATORS. It is prepared by the action of dimethyl aniline on the hydrochloride of diazobenzene sulphonic acid; on addition of caustic soda and common salt, methyl orange separates out.

Methyl Violet (*Chem.*),



Is a mixture of the hydrochlorides of penta- and hexamethylpararosaniline. *See* PARAROSANILINE. The above is the formula for the pentamethyl compound. It forms a lustrous green amorphous powder, soluble in water and in alcohol. It dyes silk and wool directly, cotton after mordanting with tannin and tartar emetic. It is prepared by oxidation of dimethylaniline in presence of phenol by means of cupric chloride (common salt and copper sulphate) at a temperature not above 60°; the solution in water is then treated with milk of lime, washed, suspended in water, and the copper precipitated by sulphuretted hydrogen. The base is extracted with warm hydrochloric acid, and precipitated by addition of common salt. *See* DYES AND DYEING.

Metol (*Photo.*) This—one of the newer substances introduced as a developer—is the sulphate of methylpara-amidometacresol, $C_6H_3CH_3OHNHCH_3 . SO_4$. It keeps well in solution with sodium sulphite, and is very energetic as a developer, giving negatives full of detail and good gradation. Combined with hydroquinone it is the favourite developer for the so-called gaslight papers.

Metonic Cycle (*Astron.*) A lunar cycle of 235 synodic months employed in finding the relation between solar and lunar years. Used for determining the time of Easter.

Metopes (*Architect.*) The square panels in the frieze of the Doric entablature separated by the triglyphs. The triglyphs are the constructive part of the frieze, the metopes being merely thin slabs either carved or left plain. In very ancient examples the spaces between the triglyphs were left open. *See* ENTABLATURE; ARCHITECTURE, ORDERS OF; *and* DORIC.

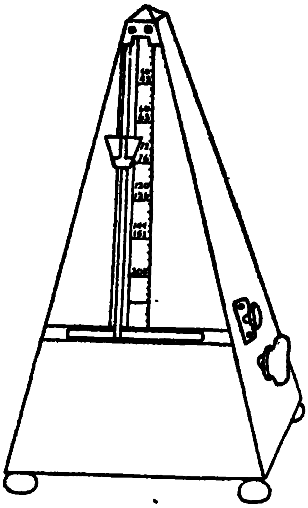
Metoquinone (*Photo.*) A compound formed by mixing saturated solutions of metol and hydroquinone in the proportion of two parts of metol to one of hydroquinone. Anhydrous soda sulphite is then added to saturation, when, after a few seconds, an abundant precipitate is obtained in the form of brilliant white particles. A formula for developments is as follows:

Metoquinone . . .	4 grains.
Anhydrous Soda Sulphite .	26 „
Water	1 oz.

Metre. The metre, which is the legal standard of length of the French Republic, was originally defined as one ten-millionth of the distance from the Pole to the Equator. It was thought that a natural standard of length could thus be obtained, but the difficulty of accurately comparing the metre with the chosen distance has proved so great that the length of a certain bar of platinum at 0° C. is now defined as the legal metre. The Earth's quadrant is (according to recent measurements) ten million eight hundred and eighty (10,000,880) metres. *See also* WEIGHTS AND MEASURES.

Metric System. *See* WEIGHTS AND MEASURES.

Metronome (*Music*). An instrument for measuring the relative length of notes and for enabling performers to ascertain the exact speed at which composers wish their works to be performed. It consists of an oscillatory steel rod (worked by clockwork action) suspended on a pivot with a fixed weight at the lower end, and a smaller and movable weight at the upper end, which by being placed nearer to the pivot increases the oscillations per minute. Behind the pendulum are figures to enable the proper adjustment of the weight to be made according to the directions on the musical composition to be timed. These directions consist of the letters M.M. (Maelzel's Metronome), and a note and figures, *e.g.* M.M. 𝅗𝅥 = 72. To ascertain this the top of the movable weight would be set at 72, and each oscillation of the pendulum would be the speed of the minims; in fact, the numbers show the number of beats per minute. Care must always be taken to see which length note is being timed (*e.g.* 𝅗𝅥 = 72 equals ♩ = 144) otherwise ridiculous mistakes will be the result. Another metronome (Pinfold's) oscillates on the finger.



MAELZEL'S METRONOME.

Mezzanine. An intermediate storey, frequently in a wing, between two storeys of the main building. The French name is ENTRESOL.

Mezzo (*Music*). Half.

Mezzo-Relievo (*Sculp.*) Sculpture in which the figures project half their true proportions from the background. *See* ALTO-RELIEVO, BASSO-RELIEVO, CAVO-RELIEVO, *and* INTAGLIO.

Mezzo-Soprano. The voice between soprano and contralto.

Mezzotint. *See* ENGRAVING (MEZZOTINT).

M.G. (*Music*). The left hand; the letters standing for the French *main gauche*. *See* M.S.

Mho (*Elect.*) A name (rarely used) for the unit of conductivity; it is equal to the conductivity of a conductor whose resistance is 1 ohm (*q.v.*) If the resistance of any conductor be *r* ohms, its conductivity is $\frac{1}{r}$ mhos.

Mi (*Music*). The Sol-Fa syllable for E.

Mica (*Elect.*) Mica is used (1) as an insulating material in cases where the latter is required in the form of thin plates; (2) as a dielectric material in condensers, on account of its high specific inductive capacity. *See* INSULATING MATERIALS *and* SPECIFIC INDUCTIVE CAPACITY.

—— (*Min.*) The name applied to a group of hydrous silicates crystallising in the monosymmetric system and showing pseudohexagonal forms. All have a perfect basal cleavage, the lamellæ being elastic. Usually transparent in thin lamellæ. *See* BIOTITE, MUSCOVITE, *etc.*

Micanite (*Elect. Eng.*) A non-conducting substance composed of small plates of mica cemented together by some non-conducting cement. It can be moulded into a variety of convenient forms.

Mica Trap (*Geol.*) *See* TRAP (*Geol.*)

Microbe (*Biol.*) A term loosely applied to certain minute organisms, especially those constituting the germs of diseases. *See* BACTERIA, BACILLI, MICROCOCCUS, SPIRILLUM, VIBRIO, *etc.*

Microcline (*Min.*) An aluminium and potassium polysilicate, $K_2O.Al_2O_3.6SiO_2$. Triclinic. It often shows a striping due to multiple twinning, and also a cording. Twinning also occurs in a simpler form. Usually white to flesh colour; but the variety Amazonstone is green. Of wide distribution as a rock forming mineral.

Micrococcus (*Biol.*) Bacteria having a short rounded form; they are found either isolated from each other, or in rows looking like a string of beads.

Microcosmic Salt (*Chem.*) A common name for sodium ammonium phosphate. *See* SODIUM COMPOUNDS.

Microfarad (*Elect.*) One millionth part of a FARAD (*q.v.*)

Micrometer. A general term for an instrument for measuring very small lengths. *See* MICROMETER GAUGE, MICROMETER EYEPIECE, SCREW GAUGE, *etc.*

—— (*Astron.*) In astronomical measurements various forms of micrometers are employed, such as the filar position micrometer, etc. They are used for measuring small angular distances in space.

Micrometer Eyepiece. An eyepiece used to microscopes, telescopes, etc., and furnished with a finely divided transparent scale, which is so placed as to be in focus at the same time as the image of the object which is viewed. The apparent size of the object or the relative sizes of its parts can be read off directly on the scale; the real size (in the case of a microscope) is found by placing a STAGE MICROMETER, which is another finely divided scale, in the place of the object, when the absolute value of the divisions of the scale in the eyepiece is at once evident.

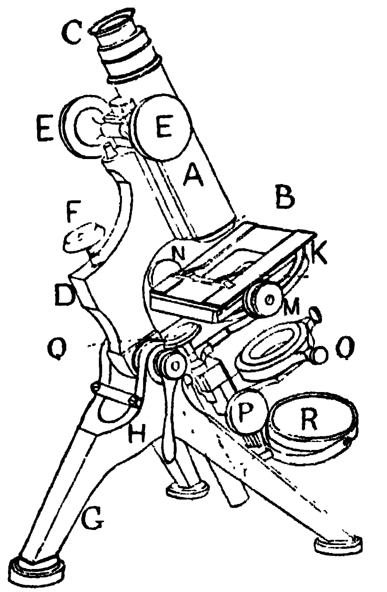
Micrometer Gauge (*Eng.*) A form of SCREW GAUGE (*q.v.*) made with jaws sufficiently wide to allow of its use as a caliper for measuring the external dimensions of objects with great accuracy.

Micro, Micr. A prefix denoting that the unit is divided by one million, *e.g.* MICROHM, one millionth of an ohm.

Micron. One millionth part of a metre.

Microphone (*Elect.*) An instrument used in the transmission of sound in a telephone circuit. It consists essentially of one or more loose contacts between conductors (usually pieces of carbon) forming part of the circuit. This loose contact is extremely sensitive, a very small vibration producing a variation in the resistance at the point of contact. If a battery and a telephone be joined in series (*q.v.*) with the pieces of carbon forming the loose contact, every vibration will cause a variation in the current, and therefore a movement of the diaphragm of the telephone and a corresponding sound in the latter. The TRANSMITTER of a modern telephone usually consists of some form of microphone; it is often termed a CARBON TRANSMITTER.

Microscope. The ordinary or COMPOUND MICROSCOPE consists of certain systems of lenses mounted in a tube or body, which is supported by a suitable stand provided with various devices for focussing, adjustment of the position of the object, concentration of light in the field of view, etc. It will be convenient to consider separately the optical and the mechanical portions of the instrument. The former comprises the OBJECTIVE, a combination of lenses, of short focal length, placed near the object to be viewed; it forms a real and considerably enlarged image of the object. A usual form of objective comprises three "double" lenses, each consisting of a double convex lens of crown glass cemented to a plano-concave lens of flint glass, the plane surface of each double lens being turned towards the object. The whole system is very carefully corrected for chromatic and spherical aberration. The equivalent focal length of the combination may vary from 3 in. down to $\frac{1}{16}$ in.; objectives of more than 1 in. focal length are, however, rarely used. For the higher powers (*i.e.* objectives of equivalent focus from $\frac{1}{8}$ in. downward) the optical properties of the objective may be greatly improved by filling the space between the cover glass of the slide and the lowest lens of the objective with some clear transparent liquid; water was originally used, but it is now customary to employ cedar wood oil, which possesses optical properties closely approaching those of glass (*i.e.* it has nearly the same refractive index and dispersive power). An objective intended for use in this manner is termed an OIL IMMERSION OBJECTIVE. The image formed by the objective is viewed by means of an EYEPIECE, which produces a virtual and enlarged image of the original (and real) image. The eyepiece usually consists of two lenses mounted in a short tube; in the form generally employed, known as the HUYGHENS EYEPIECE, the lenses are plano-convex: their focal lengths are in the ratio 3:1, and the distance between them is equal to the difference of the focal lengths. Other forms are also used, *e.g.* the RAMSDEN EYEPIECE (*q.v.*) A microscope is also fitted with a mirror, as shown at R in the figure; this serves to reflect light up through the slide. In most modern microscopes a plane and a concave mirror are fitted back to back in the same mount, so that either may be used at will. A CONDENSER is another device for the concentration of light. It may consist of a single convex lens placed on a separate stand, and arranged to focus a beam of light on the top of an opaque slide, or it may be some form of SUB-STAGE CONDENSER. This is a system of lenses (often provided with an adjustable diaphragm) fitted beneath the stage, *i.e.* between the mirror and the slide. In the figure the sub-stage O carries the condenser. A PETROLOGICAL MICROSCOPE is adapted for the examination of minerals by polarised light. A POLARISER (*q.v.*) is fitted to the sub-stage, and a NICOL PRISM (*q.v.*) fitted to an eyepiece serves as an analyser. *See also* POLARISATION. The mechanical arrangements of a microscope are shown in the figure, which is a somewhat diagrammatic representation of an instrument of Watson's Van Heurck model. A is the BODY, or tube, provided with a female screw at B, into which the objective is screwed; the eyepiece C slides into the top of the tube. The body is supported on the main frame D, and can be moved up and down by means of a COARSE ADJUSTMENT consisting of a rack and pinion, the latter being actuated by milled heads E, E. Accurate focussing is obtained by means of a fine threaded screw acting on the body through a lever and turned by a head F. The frame is supported by a strong claw foot G, and can be tilted and clamped at any angle by a locking nut furnished with a handle H. K is the STAGE. This can be completely rotated, while the upper part L, which carries the slide,



MICROSCOPE.

possesses linear traversing motion along two directions at right angles to each other, given by milled heads M and N. O is the SUB-STAGE, furnished with set screws for holding a condenser or polariser; it can be rotated in its support, and can also be raised or lowered by means of a coarse adjustment P and a fine adjustment Q. The illuminating mirror is shown at R. When two or more objectives have to be used in succession, it is convenient to fix them to a NOSEPIECE, a device attached at B. This enables either objective to be brought into position by means of a pivoted arm.

Microscope, Commercial Uses of. In addition to the purely scientific use made of the microscope, there is an extensive field for its continual employment in commercial circles and in industrial manufactures. There is scarcely any industry of importance in which the microscope does not play a prominent part. In the manufacture of IRON AND STEEL it is constantly resorted to in order to test and control the quality of finished goods, such as girders, boiler plates, and other steel structures in which strength and uniformity of material are of the utmost importance. Researches with the microscope have shown that very minute flaws in the material may lead to serious defects in steel structures, and steel being now so largely employed in buildings, it is evidently of the greatest importance that there should be some means of detecting flaws or defects in the metal. The manufacture of METAL ALLOYS also demands a continual reference to the microscope, as it is possible to measure the value and composition of an alloy by its appearance under the microscope. It also serves to determine very largely the physical changes due to the mixture of one metal with another, and whether the alloy is

homogeneous. It further affords a means of indicating the nature of the alloy produced, both as to structure and composition. In the ENGINEERING INDUSTRY the microscope finds employment for measuring minute differences in dimensions. Thus in the construction of instruments in which small alterations of length have to be measured with great accuracy, the microscope is the only satisfactory instrument for determining such differences. For example, it may be necessary to determine the actual alteration in length of a metal bar produced by an increase in temperature. The increase in length produced by a rise in temperature is, of course, a very small quantity, but the ratio of expansion is readily and accurately determined by means of the microscope. The sizes of flaws in metal, or of minute holes, are all exactly measured in this way. In the TEXTILE AND ALLIED INDUSTRIES the microscope is as essential for efficient and economical work as any other appliance in the factory. Thus in woollen industry the examination of raw materials can only be properly carried out with the microscope, and by its aid it is easy to determine the nature of the various wools used. The microscopical appearance of wools from sheep, goats, and other animals are all capable of classification, so that the manufacturer can readily determine the composition of the woollen goods which may come under his notice. The cultivators of silk, as well as the manufacturers, employ the microscope for ascertaining quality of thread, dimensions of the thread, and other factors. In the allied industries of ROPEMAKING, HAT MANUFACTURE, PULP AND PAPER INDUSTRIES, all of which trades depend on vegetable or animal fibres as their staple raw material, the microscope is relied upon as the instrument for a proper examination of not only the raw products, but more particularly the finished goods. The manufacturer is enabled by its means to examine the finished goods of his competitor in order to determine the materials used in the manufacture of such articles. In the matter of the raw material the microscope is not so essential as with the finished goods, because before treatment the raw material has marked physical differences visible to the eye. Thus in the case of paper the raw materials employed may be rags, hemp, jute, wood pulp, or esparto. In the raw condition these cannot be mistaken, but it is afterwards somewhat difficult to say what a given paper is made of by a mere inspection of a sample. The microscope is also largely employed in BREWING and BAKING in controlling the condition of the ferments necessary for the business. By this means they can be watched and used at the right time and to the fullest advantage. The makers and users of STARCH, FLOUR, MEAL, and similar products are also indebted to the microscope as a means for determining their nature, origin, and commercial value. It is interesting to note that the well known "Hovis" flour was the result of a careful microscopic investigation by Mr. Richard Smith. The examination of MILK, BUTTER, and other products of this kind by means of the microscope has thrown a great deal of light upon the necessity for absolute cleanliness and up-to-date methods in the handling of such perishable goods, and this industry can no longer be carried on in a haphazard manner; in fact, the preparation of almost every kind of foodstuff is controlled by means of the microscope. The examination of fruits, jams, and tinned goods are only a few other instances. The CHEMIST AND DRUGGIST determines the purity or otherwise of his drugs in a similar manner. The MEDICAL OFFICER OF HEALTH finds the microscope indispensable for the detection of adulteration in samples of food and the many hundreds of articles sold for domestic use. Without the microscope the purity of water and its freedom from bacteriological germs could not be ascertained, and the microscope is continually at work in this direction. The examination of SEEDS for farmers, florists, and fodder growers by means of the microscope is now a process of common and daily use. The suitability of STONES as material for BUILDING, the MAKING OF ROADS, etc., can also be determined by means of the microscope, thin sections of the various materials being prepared for examination. In detecting CRIME the microscope has long played an important part. Without it HANDWRITING EXPERTS would be almost helpless, for it enables them to determine very minute alterations in writing, differences in the nature of the ink employed, and any erasures upon the surface of the paper. In this way the microscope is a valuable adjunct to the art of photography. Finally, the value of the microscope for the examination of bloodstains and the detection of crime is now well known to the readers of the daily papers. *See* METALLOGRAPHY.

Mid *or* **Middle Gear** (*Eng.*) *See* LINK MOTION.

Midden *or* **Privy System** (*Hygiene*). This system, which at one time was largely prevalent in this country, but is now mainly confined to the northern and midland districts, aims at the deodorisation and drying of the excreta by admixture with ashes. Formerly the receptacles were mere holes in the ground, and their contents overflowed or percolated into the soil, thus poisoning the water in neighbouring wells. At the present day middens must be constructed according to certain definite rules. A model byelaw of the Local Government Board prescribes that a midden or privy shall be at least 6 ft. from any dwelling and 40 or 50 ft. from any well; the floor must be not less than 6 in. above the ground level, must be paved, and have an inclination towards the door of ½ in. to the foot. The capacity of the receptacle must not exceed 8 cubic ft., thus necessitating a weekly removal; it must be of impermeable material, not communicate with any drain or sewer, and have a hinged seat to admit of the application of ashes.

Middle C (*Music*). That note which stands on the middle line of the Great Stave of eleven lines, hence its position in the Treble and Bass Staves respectively as follows:

Middle Distance (*Art.*) That portion of a picture which is represented as lying between the foreground and the background.

Middle Oil (*Chem.*) That part of coal tar which distils between 170° and 230°. From it are obtained the important substances naphthalene (*q.v.*) and phenol (*q.v.*)

Middle Rail (*Elect. Eng.*) A heavy conductor in the form of a rail carried on insulating supports, which is laid between the running rails of an electric railway to supply current to the motors. Often termed the THIRD RAIL or LIVE RAIL.

Middle Rail (*Join.*) In framing, *e.g.* in a door or partition, the rail (*q.v.*) above the bottom rail.

Middling Spaces (*Typog.*) Spaces, used to divide words, four to an em of a particular body.

Midfeather (*Paper Manufac.*) A partition fixed in the "breaker" to promote circulation of the pulp.

Midfeather Trap (*Hygiene*). This consists of a round or square box, with an entry tube on one side and an outlet tube at an equal height on the other. A partition passes down between into the water, which stands up to the lower margin of each pipe. The trap is not self cleansing, and otherwise fails in all the essentials of a good trap.

Midnight Sun (*Astron.*) When the latitude of a place is greater than the polar distance of the sun or its co-declination, the sun will not set, but will make a complete circuit of the heavens. At midnight, therefore, the sun will be visible; hence the "midnight sun."

Migration of the Ions (*Elect.*) *See* IONS, MIGRATION OF.

Mil (*Elect. Eng., etc.*) The one-thousandth part of an inch. Used to denote the diameters of wires, thickness of transformer plates, etc., instead of the numbers in the WIRE GAUGE (*q.v.*), since it is more convenient in electrical calculations to have these measurements given at once in inches.

Mild Alkali. *See* ALKALI.

Mild Steel (*Eng.*) Steel which contains a low percentage of carbon; it resembles wrought iron very closely, and can be welded. *See* STEEL.

Mile. *See* WEIGHTS AND MEASURES.

Milk (*Foods*). Consists of casein (albuminoids), fat, carbohydrates, salts, and water, and thus contains all the constituents of a standard diet. Cow's milk contains more casein and salts and less carbohydrates than human milk, so that in employing it as a food for infants it is necessary to dilute it and add milk sugar. In the process of digestion the curd (casein and fat) of human milk forms a loose, flocculent mass, easily assimilated, whilst cow's milk clots in masses digested with difficulty. In the artificial rearing of infants this is remedied by the addition of barley water to the cow's milk. By Sec. 3 of the Sale of Foods and Drugs Act, 1879, an inspector may take a sample of milk for analysis which is consigned from one person to another. The sample must be taken at the place of delivery. Vendors of milk and cream must exhibit their name and address on the vehicle or receptacle from which the milk is sold (Sec. 9). Sec. 11 provides that condensed, separated, or skimmed milk shall not be sold, or exposed for sale, except in receptacles labelled so that the words are plainly visible to the purchaser. *See also* COW'S MILK, CURD OF MILK, *and* FOODS.

——, **Humanised** (*Foods*). Produced by the addition of cream and sugar of milk to sterilised cow's milk, thus supplying the deficiency of fat and sugar.

Milk of Lime (*Chem.*) *See* CALCIUM COMPOUNDS.

Milk of Sulphur (*Chem.*) *See* SULPHUR.

Milk, Pasteurised (*Foods*). When raised to a temperature of 180° F. milk is said to be Pasteurised.

——, **Sterilised** (*Foods*). Milk is sterilised, and thus preserved from fermentation and decomposition, by raising it to a temperature of 212° F. *See also* STERILISATION.

Milk Sugar (*Chem.*) *See* LACTOSE.*

Milky Way (*Astron.*) *See* GALAXY.

Mill. (1) A general term for a factory. (2) A machine (or set of machines) for grinding a substance.

Millboards (*Bind.*) The boards which are attached to the unbound book by "lacing in" (*q.v.*) When covered with leather, cloth, or other substance they form the covers of the book. Millboards are made from various materials, the best from old rope; the cheapest from straw, jute waste, etc.

Milled Head. The head of a screw provided with corrugations on its edge to enable it to be turned by the fingers; used on adjusting screws, etc.

Milled Lead (*Plumb.*) Sheet lead that has been rolled.

Millerite (*Min.*) Sulphide of nickel, NiS. Nickel = 64·9, sulphur = 35·1. Rhombohedral, usually in extremely fine, hairlike crystals; hence the name HAIR PYRITES. Brassy yellow when fresh. Found in several localities in the British Isles sparingly, especially in Cornwall and Devon; also in Bohemia, Saxony, and the United States.

Millet (*Botany*). Various species of millet, *Pennisetum typhoideum* (order, *Gramineæ*), are important food plants in India, Egypt, and West Africa. *See also* DHURRA.

Milli-. A prefix to the name of a unit, denoting that the unit is divided by one thousand, *e.g.* MILLI-AMPÈRE, one-thousandth of an ampère.

Millimetre. *See* WEIGHTS AND MEASURES.

Millimetre Pitches (*Eng.*) Screw threads whose pitch is a simple decimal fraction of the metre.

Milling (*Coins*). The grooves or indentations on the edge of a coin.

—— (*Eng.*) (1) Cutting metal, etc., by means of revolving circular cutters, having teeth of various shapes to suit the work in hand. The cutter is called a MILLING CUTTER, and is attached to a rotating spindle (which is either horizontal or vertical) driven by a machine termed a MILLING MACHINE, provided with a traversing table for holding the work. This table can move vertically as well as horizontally, and can also rotate about a vertical axis, so that any part of the work can be brought under the cutter as required. (2) The production of indentations or corrugations round the edge of a screw head, etc. *See* MILLED HEAD.

—— (*Woollen and Worsted Manufac.*) *See* FELTING.

Milling Machine (*Eng.*) *See* MILLING.

Milling Tool *or* **Wheel** (*Eng.*) A small steel wheel with corrugations on its edge which are the counterpart of those required to be produced on a milled head (*q.v.*) The steel wheel runs loosely on its axle, which is supported by a suitable handle, by which it is pressed against the blank as the latter revolves in the lathe.

Millon's Reagent (*Chem.*) Mercury is treated with its own weight of 63 per cent. nitric acid first in the cold and then with gentle warming till solution occurs: to the solution twice its volume of water is added, and it is allowed to stand till the precipitate subsides. The clear liquid is Millon's reagent. It gives a white precipitate with proteids, which turns brick red on boiling. Phenol and many of its derivatives give Millon's reaction.

Mill Race. The channel in which water is led to a mill wheel.

Mill Reams (*Paper Manufac.*) Reams of hand made paper consisting of 472 sheets.

Mill Rine, Mill Rind, *or* **Fer de Moline** (*Her.*) The iron which is fixed to the centre of a millstone. Used in conventional forms as a charge.

Mill Rolls (*Eng.*) The steel rollers used in the manufacture of bar iron.

Mimas (*Astron.*) The innermost satellite of Saturn.

Mimetese (*Min.*) An arseniate and chloride of lead, $3(Pb_3As_2O_8) . PbCl_2$. Hexagonal, occurring in yellow or brown crystals resembling Pyromorphite. Also called MIMETISITE and GREEN LEAD ORE. From Cornwall, the Caldbeck Falls in Cumberland, Saxony, Bohemia, etc.

Mimetisite (*Min.*) A synonym for MIMETESE (*q.v.*)

Mineral. The term mineral as used by commercial men signifies any native substance which is mined or quarried. In this sense freestone, fireclay, brick earth, oilshale, coal seams, and many other substances count as minerals. Amongst men of science the meaning attached to the word is much more restricted. They understand a MINERAL SPECIES to be an inorganic native compound whose chemical and physical properties vary so little in a large number of examples that these characters can be expressed in a short and definite description, by means of which any other specimens of that substance can be easily identified.

Mineral Acids (*Chem.*) A name used to denote the commoner inorganic acids. The *strong* mineral acids are hydrochloric, nitric, and sulphuric.

Mineral Chameleon (*Chem.*) A name given by Scheele to potassium manganate (*see* MANGANESE COMPOUNDS) because of the series of colours it gives on treatment with water—green, blue, violet, rose.

Mineral Dyes. *See* DYES AND DYEING.

Mineralogy. The systematic or scientific study of MINERALS (*q.v.*) It includes the determination of their chemical constitution, their physical characteristics, modes of formation, the measurement, description, and classification of their crystalline forms, investigation of their modes of occurrence and localities, and their economic values. The science thus possesses many points of contact with the sciences of Geology, Petrology, Metallurgy, and Mining, and may be considered to include the subsidiary science of Crystallography. *See also* SYSTEMS OF CRYSTALS.

Mineral Oils. The PARAFFIN class of hydrocarbons. *See* PARAFFINS.

Mineral Veins (*Geol.*) Fissures in the Earth's crust which have been filled with mineral substances of a nature different from that of the rock in which they are enclosed. These substances may be Quartz, Calcite, Dolomite, Barytes, Fluorspar, or, less frequently, any one or more of a few other substances. In nearly all cases mineral veins have been filled by the agency of water. *See* METALLIFEROUS VEINS.

Mineral Waters (*Chem.*) *See* WATER.

Mineral Wax (*Chem.*) Ozokerite (*q.v.*)

Miner's Dial (*Surveying*). An instrument used for determining the direction of lines. It consists essentially of a magnetic needle pivoted at the centre of a horizontal circle graduated into 360°, and provided with sights through which to observe stations on the line.

Minerva Machine. *See* TYPOGRAPHY.

Mine Tin (*Met.*) Tin ore extracted from a vein by mining instead of being obtained from alluvial deposits. *Cf.* STREAM TIN.

Miniature (*Paint.*) A portrait of very small dimensions generally executed in watercolours on ivory, vellum, or similar substance. The term was originally applied to the small watercolour drawings that adorned ancient manuscripts, and which were painted with *minium* or red lead.

Minim (*Music*). *See* NOTES.

Minimum Deviation (*Phys.*) The smallest angle through which a ray can be bent or deviated from its original path when acted on by a refracting system, such as a prism, etc. In the case of a prism, the minimum deviation occurs when the path of the refracted ray within the prism makes the same angle with the two sides of the prism.

Minimum, Minima (*Math.*) *See* MAXIMA AND MINIMA.

Minimum Thermometer (*Heat*). *See* MAXIMUM AND MINIMUM THERMOMETERS.

Mining. The term mining includes those processes by which the useful and precious minerals are explored, extracted, and dressed. It includes: (1) The search for the irregular veins or deposits of gold and other metals, and the comparatively regular seams of coal or ironstone; (2) the operations by which these minerals are "won"; (3) the arrangements adopted for their utmost utilisation. Two classes of minerals are worked—the metallic and the non-metallic. The most important examples of the former class are iron, gold, silver, copper, lead, tin, zinc, manganese, and arsenic; of the latter, coal, slate, gypsum, chalk, limestone, mica, salt, clays, and precious stones. The metallic minerals usually occur in rocks that have undergone more or less metamorphism or change, while the non-metallic are generally found in beds or stratified deposits. In searching for the former minerals, therefore, regions must be chosen where the greatest disturbances and upheavals have occurred, accompanied by great contortions of the rocks, eruptions of volcanic matter, and the formation of faults. Owing to the violent disturbances, the strata have been changed or metamorphosed and crystallised by heat. Metallic ore bodies are to be found here and in the fissures and other openings in the earth's crust. In most cases the vein-filling of metal bearing deposits has been accomplished by water, consequently porous rock formations are more likely to contain metallic ores than hard impervious strata. Very often ore deposits are to be found at the junction of two different rock formations. Bedded minerals, such as coal, stratified ironstone, fireclay, etc., occur in distinct layers. A BED or SEAM is a member of a series of stratified rocks. As the different non-metallic minerals are generally found in certain formations, and as they generally occupy one well defined position, the search for them is rendered comparatively simple. But all deposits are subject to irregularities. These may be due to their original mode of formation or to subsequent disturbances forming faults, heaves, throws, washouts, etc. (*q.v.*) In determining the position of veins, ore deposits, and seams it is generally necessary to make use of all the geological data available, to bore trial holes

through the various measures, or to drive tunnels or levels underground. The mode of occurrence of the various minerals greatly influences the method of winning them. Metals being found in veins, alluvial deposits, fragmental deposits or placers (*q.v.*) are worked in a different manner from seams of coal or masses of slate. The method adopted in any particular case must be the one most suited to that deposit, the object always being to extract as much mineral as possible from a given space at a minimum of cost. The various operations by which the minerals are extracted may be thus enumerated: (1) Opening the mine, (2) methods of working, (3) timbering, (4) tools and appliances, (5) haulage, (6) transmission of power, (7) machine mining, (8) winding, (9) draining, (10) ventilation and lighting. (1) OPENING THE MINE: A mine may be opened either by shafts or levels, and the location of the surface plant and mine opening will depend primarily on the nature and extent of the deposit, and secondarily on the facilities for obtaining water and for transporting the product to the market. If the shaft or tunnel is to be permanent it must be of a predetermined capacity. This will depend chiefly upon the output required; and this again will be determined by the thickness and extent of the deposit and the efficiency of the proposed hoisting and banking arrangements. Shafts are made circular, rectangular, or elliptical, according to the nature of the strata and the amount of timber or bricks available. They vary in size from 10 or 12 ft. to 20 or 24 ft. in diameter. Tunnels are driven where the mineral is near the outcrop, and these may be either in a level direction or inclined up or down, according to the inclination of the deposit or seam. They are generally rectangular in shape, though sometimes they are formed with straight sides and a semicircular arch above, lined with timber or brickwork. The mode of operation in sinking a shaft depends upon the character of the strata passed through and the quantity of water encountered. Ordinarily, sinking may be said to consist in boring holes for blasting, filling, sending up and banking the *débris*, and supporting or walling the sides. The holes are bored either by hand drills, hand machine drills, or power drills, the latter having been introduced during recent years for this work with good results. Explosives are then used for dislocating the rock, after which the *débris* is filled into hoppets and sent to the surface. If water is met with in large quantities it is necessary either to spend many hours per day in winding it (*i.e.* raising it by winding gear) or to erect adequate pumping machinery. Tunnels and drifts, though driven more or less horizontally, are excavated in a similar manner. In sinking or tunnelling through quicksand or other water bearing strata, special methods are adopted. (2) METHODS OF WORKING: These may be divided into OPEN WORK and CLOSED WORK. The former includes the working of all deposits having no overbearing strata or those in which the overlying material is removed by hand or machinery from the deposit. Thus all quarries and fragmental deposits or placers are open work. There are many advantages of such a system of working: underground roadways have not to be kept open and in good repair; there is less danger from accidents due to falls of ground, blasting, or accumulations of gas; the men work under healthier conditions and are enabled to select and extract the ore more easily. Open work may be divided into two general classes: (*a*) Where the greater portion of the deposit is valuable and has to be removed, (*b*) where the valuable portion is only a small part of the whole deposit. In the first case, as in quarrying and in ordinary mines, the material is removed by hoists, cableways, or tunnels; or, again, the deposit may be stripped and tunnels driven through the material from valleys or adjacent shafts: this is known as the MILLING SYSTEM. Placers may be worked by means of a stream of water from a nozzle directed against the deposit. When the material has been loosened it is directed so as to flow through sluices to the dressing tables. This is known as HYDRAULIC MINING. Placer deposits may also be worked by mechanical means. If a metal-bearing deposit lies below water level, the material is raised by means of a dredge. CLOSED WORK includes numerous methods of both coal and metal mining. In the case of regular bedded deposits, such as coal, fireclay, and ironstone, elaborate systems can be adopted which are impossible in irregular deposits interrupted by faults, etc. In the case of a vein the shaft is sunk on the course of the lode, and so as to intersect it at a depth of 500 or 600 ft. From the shaft, at intervals of 30, 40, or 50 yards, crosscuts are driven to the lode, and from the point of intersection levels are driven parallel with it. The material is then got out by means of UNDERHAND or OVERHAND STOPING: underhand stopes are workings arranged like steps, the miner filling the ore from the floor into boxes, working gradually down in a series of terraces. In overhand stoping the ore is broken down from above as the working progresses. Wider lodes and certain beds are worked by modifications of these systems. In working coal seams, main roads or levels are driven in different directions, and after leaving a solid pillar of coal to protect the shaft of 50 to 150 yards in diameter, the workings are opened either on the PILLAR AND STALL or the LONGWALL system. In the former method the estate to be gotten is divided or cut into a series of separate blocks, panels, or pillars by pairs of narrow tramroads, after which the pillars are got out one by one, generally starting from the boundaries of the estate; this system is called STRAITWORK. By longwall is meant the method of taking out the whole of the coal in one long wall or face without first driving narrow roads, the access to and from the face being by means of roads constructed through the waste or goaf, and formed of the dirt or shale obtained in excavating the mineral; this is known as WIDEWORK. In thin, thick, or highly inclined seams modifications of one or the other of these systems are adopted. (3) TIMBERING: The supporting of the roadways and workings of a mine is a very important consideration. The chief timbers used are those called soft woods, such as fir, pine, and larch, whose chief characteristics are straightness, regularity, and lightness. For bars and other supports requiring special strength a few hard woods are used, such as oak and beech. Many arrangements of props, bars, sprags, chocks, etc., as the various mining timbers are called, are adopted according to the nature of the roof, floor, and sides, and the height of the excavations. In metalliferous mining it is usual to joint sets of timber together so as to completely support all sides; in coal mining the roof only may need support, although it is invariably the custom to timber the sides of roadways as well as the roof. For some purposes brickwork, masonry, and concrete are employed, while iron and steel props and bars are now coming into use. (4) TOOLS AND APPLIANCES: As the strata in which the miner works is generally of a

very hard nature, it is necessary that all his tools should be of good quality, and especially those tools which daily become worn and need continual sharpening. The most common tools are picks, shovels, hammers, wedges, and drills. The appliances include apparatus for charging and firing shot holes, and instruments for setting and drawing props. (5) HAULAGE: The haulage of the mineral from the workings to the shaft is done to a great extent by either men and horses or by machinery and ropes and chains. The roads along which the tubs or corves are drawn are called ENGINE PLANES or HAULAGE ROADS. Ropes or chains cannot be employed along all underground ways, consequently it is necessary for the miner to haul the coal along the faces and drawing roads. The tubs run on bridge or flange rails laid on wooden sleepers, points and shunts being fixed where necessary, and pulleys arranged overhead, in the case of engine planes, to direct the rope. (6) TRANSMISSION OF POWER: For the purposes of hauling, coal cutting, and pumping it is necessary to transmit power from the surface to the workings. Engines or motors driven by steam, compressed air, or electricity are used. As steam is often a serious danger underground, the two latter sources of power are substituted. The former is the safest means, and is a common motive power in the chief metalliferous fields and in many coal mines. During recent years the extension of electric power to mining work has been remarkable, and it is now used in many cases for every class of work both above and below ground. (7) MACHINE MINING: Machines have superseded hand labour in many departments. Power machine drills are used for drilling holes in shafts, tunnels, and at the working face; HEADING and SHEARING machines are used to cut the sides of roadways, and various forms of mechanical cutters are in use for undercutting coal. (8) WINDING: The hoisting of the mineral from the workings to the surface is carried on in both inclined and vertical shafts by means of several appliances, the essential parts being a WINDING ENGINE, which actuates a drum carrying a rope, the latter being alternately coiled and uncoiled from the drum. If the shaft is a deep one other appliances are installed, by means of which the load may be balanced at all parts of its journey, thus reducing the strain on the winding engine. Guides of wood or iron, or wire ropes, are used to keep the cages steady in their transit, and safety keps or catches are fixed at top and bottom to prevent the cages accidentally falling down the shaft. (9) DRAINING: Directly the miner gets below the surface of the ground he is liable to be impeded by water, which may constantly increase in amount as the sinking or workings get deeper. If the quantity of water is not large, it may be got out by winding or by means of water levels and drainage tunnels. These latter are very useful in hilly districts. When pumps are used, two general systems are employed: (*a*) the pump may be placed underground and operated by an engine on the surface, power being transmitted by rods; or (*b*) both engine and pump may be placed underground, the former being driven by steam, compressed air, hydraulic, or electric motor. The types usually employed are Cornish pumps, lift or force pumps, pulsometers, centrifugal pumps. (10) VENTILATION AND LIGHTING: The successful ventilation of a mine may be briefly described as keeping the atmosphere of the mine in as healthy and pure a condition as possible without useless expenditure. To accomplish this is one of the most important duties of the mining engineer. As the natural ventilation of the mine is rarely sufficient, a current may be produced either by a furnace or fan. Both arrangements depend for their success on the establishment of a difference in pressure of the air in the intake and return currents. In the former case this is achieved by heat, just as a draught is caused in a room by a fire; in the latter case a depression is obtained by means of the fan's action, the air flowing in all cases from the point of greater pressure to the point of depression. Underground the air is conducted by means of air doors, screens, air pipes, crossings, stoppings, etc., to the utmost limits of the mine, thus supplying fresh air to the workman and carrying off the noxious gases produced by the firing of shots, the breathing of men and horses, or escaping from the strata. Mines are lighted by safety lamps, candles, torches, or electricity. In fiery mines, safety lamps only can be used. In safe mines, and during the sinking of shafts or tunnels, candles are most common. Electricity is used in the neighbourhood of the shaft bottom, but so far has been found unsuitable for use in the workings. After the ore leaves the mine it must be DRESSED before it is ready for use. For this purpose every mine has its own more or less extensive and elaborate arrangements for dealing with the raw material. It is put through various processes, including crushing, stamping, screening, sizing, classifying, washing, and concentrating, after which it is loaded into wagons or barges and sent to the market. ORE DRESSING AND PREPARATION OF COAL: The object of crushing ore or coal is to free the valuable constituents from the gangue or other worthless constituents, so that they may be afterwards separated, or crushing may be done in order to reduce the size of the individual pieces. The various types of machines for crushing are jaw crushers, gyratory crushers, cracking or disintegrating rolls, roller mills, stamps, and hammers, all of which are designed to reduce the raw material to a convenient size for the subsequent processes. After crushing, the material passes to the screening and sizing machines, where the various sizes are separated from each other. CLASSIFIERS and CONCENTRATORS are machines for thoroughly separating the ore from the gangue or for taking out the dirt from the coal. In both cases the principle employed in doing this is the same, *viz.* making use of the varying specific gravities of different minerals. The material is washed by water into special JIGS or troughs, and while the water is in motion the heavier particles fall to the bottom, the lighter ones arranging themselves in layers according to their density. It is owing to the introduction of greatly improved dressing machines that many deposits of ore and seams of coal are now being worked which formerly were considered of little value, because of the small proportion of valuable products contained in them in the one case, or the large quantities of dirt and inferior coal intermixed in the other.—J. T.

Minion (*Typog.*) Type between brevier and emerald in size. *See* TYPE.

Minium (*Chem.*) A common name for red lead. *See* LEAD COMPOUNDS.

—— (*Min.*) A compound of lead and oxygen now regarded as a lead plumbate, $2PbO \cdot PbO_2$; of the same composition as RED LEAD (*q.v.*) It is a rare mineral, occurring as a pulverulent decomposition product of other lead ores. It has been sparingly found at many localities where Galena or Cerussite occurs.

Minivor. A white fur obtained from the Siberian squirrel, used on peers' robes.

Minnikin (*Typog.*) The smallest size of type made.

Minor (*Music*). Lesser. *See* MAJOR.

Minor Axis. The shorter diameter of certain figures, *e.g.* of the Ellipse.

Minore (*Music*). Minor; used sometimes when a piece goes from the major key to that of the tonic minor. *Cf.* MAGGIORE.

Minor Planets (*Astron.*) A multitude of small planets which revolve round the sun between the planets Mars and Jupiter.

Minor Tone (*Sound.*) The ratio of the two notes of frequencies 10 and 9, *i.e.* the interval $\frac{10}{9}$.

Minotto Cell (*Elect.*) A modification of the DANIELL CELL (*see* CELLS, PRIMARY), having a flat copper plate lying at the bottom of a jar, covered by a mass of sawdust. The zinc plate rests on the latter, and the porous pot is dispensed with.

Minster. Originally the name for a monastery; subsequently the name signified the church attached to a monastery, and more recently a cathedral church, *e.g.* York Minster.

Minute. *See* WEIGHTS AND MEASURES.

—— (*Architect.*) *See* MODULE.

Mirabilite (*Min.*) Native Glauber Salt, hydrous sodium sulphate, $Na_2SO_4 . 10H_2O$. Soda = 19·3, sulphuric acid = 24·8, water = 55·9 per cent. Monosymmetric; also as a white efflorescence. It loses its water on exposure to air and becomes opaque. From Kirkby Thore in Westmorland, Hallstadt in Austria, Bohemia, etc.

Mirage (*Meteorol.*) An appearance suggesting water, seen in hot countries, and due to total internal reflection from a layer of hot and rarefied air lying next to the heated ground.

Mirbane, Essence of (*Chem.*) A common name for nitrobenzene (*q.v.*) It is used as a cheap flavouring agent in confectionery, etc.; it has a sweet almond-like smell: it is poisonous.

Mirror (*Phys.*) An object having a polished surface of regular form; the principal forms are plane, concave, and convex. The latter are commonly portions of spheres; but for certain purposes mirrors are made PARABOLIC in form. *e.g.* when required for use in reflecting telescopes.

Mirror Galvanometer (*Elect.*) *See* GALVANOMETERS.

Miserecorde (*Arms*). A slender dagger, generally three sided, intended to enter the joints of armour to give the *coup de grace* to a fallen antagonist. Worn by knights and others on the right hip.

Miserere (*Architect.*) A hinged bracket on the underside of a stall seat in a church, on which, when the seat was turned back, an ecclesiastic could rest without actually sitting down.

Mispickel (*Min.*) Sulpharsenide of iron, FeAsS. Iron = 34·3, arsenic = 46·0, sulphur = 19·7 per cent. Orthorhombic; also, and more often, massive. Tin-white to steel grey; sometimes contains cobalt or nickel. In association with other metalliferous ores in Cornwall, Devonshire, Cumberland, Saxony, Bohemia, the United States, etc.

Missal. The name applied to a manuscript or printed book containing the office or prayers of the Mass used in the Roman Catholic Church. They are often designed after the style of mediæval manuscripts.

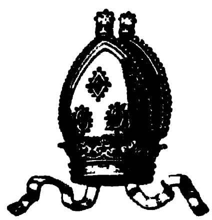
Mist (*Meteorol.*) *See* FOG.

Mistral (*Meteorol.*) The cold N.W. winds of Mediterranean France, generally occurring in the winter.

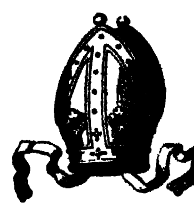
Miter (*Carp., etc.*) An alternative spelling of MITRE (*q.v.*)

Mitis Castings (*Eng.*) Castings made by fusing wrought iron with a trace of aluminium, and pouring into a mould of special construction. Objects produced this way have practically all the properties of forgings, and the process will probably become increasingly common.

Mitre (*Cost.*) A ceremonial headdress, pointed and cleft at the top, worn by prelates and sometimes by abbots. Originally the mitre was a plain head band or bonnet, with two lappets at the side. It



MITRE OF BISHOP OF DURHAM.



MITRE OF BISHOP.

assumed the present form in the fifteenth century. The mitre of the Bishop of Durham rises from a ducal coronet; the mitre of a Bishop rises from a circlet.

—— (*Her.*) An ecclesiastical cap denoting rank and dignity. It is sometimes used as a charge, but where it appears as a badge of office it replaces the crest ordinarily found above the arms, and the helmet is discarded. On the arms of Berkeley, fourteenth century, this crest is seen with helmet and mantling.

Mitre Arch (*Build.*) An arch consisting of two stones in the form of a gable. It is not, strictly speaking, an arch.

Mitre Board *or* **Shoot** (*Carp., etc.*) A board provided with a guide or fence set at a suitable angle for planing the end of a piece of wood which is to form part of a mitre joint. The mitre board is used when the joint has not been cut with sufficient accuracy by the use of the saw and mitre box (*q.v.*)

Mitre Box (*Carp., etc.*) A device for guiding a tenon saw in order to cut off the end of a piece of wood at an angle (usually 45°) in making a mitre joint.

Mitre Clamp (*Carp., etc.*) A device for holding the members of a mitre joint in position while being glued up or otherwise fastened.

Mitred Clamp (*Carp. and Join.*) A piece of wood forming a border at right angles to the grain of a board and mitred at the ends.

Mitre Joint. A joint between two pieces of material which meet at an angle, the two pieces being so cut that there is a plane surface of contact bisecting the angle. In the commonest cases the joint is right angled, and the surface of contact is formed by cutting off the end of each piece at an angle of 45°.

Mitre Shoot (*Carp., etc.*) *See* MITRE BOARD.

Mitre Square (*Carp., etc.*) A steel blade set in a stock at an angle of 45° for testing the accuracy of mitre joints.

Mitre Wheel (*Eng.*) A bevel wheel whose teeth are at an angle of 45° with the axis.

Mitring (*Bind.*) Finishing or ornamenting the cover of a book with straight lines which meet each other without overrunning.

Mixing (*Cotton Manufac.*) A system of combining cotton fibres possessing similar characteristics with the object of (*a*) reducing the cost of spun thread, (*b*) altering the shade or colour of thread, (*c*) improving the spinning and quality of a lower grade of cotton.

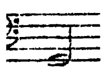
Mixing Chamber (*Eng.*) The space in gas and petrol engines in which the explosive gas is mixed with air; sometimes this occurs in the cylinder itself.

Mixing Jet *or* **Mixed Gas Jet.** *See* OXYHYDROGEN FLAME.

Mixolydian (*Music*). *See* MODES.

Mixture (*Chem.*) Two, or more, substances, associated together, but not combined. *Cf.* COMPOUND.

Mixture (*Music.*) An organ stop which controls several ranks of comparatively small pipes to each key. The most frequently found mixture is that of three ranks, consisting generally (though other combinations will sometimes be found) of the 17th, 19th, and 22nd of the 8 ft. tone. With this combination the result, when



is played with the mixture stop only drawn, will be

As the scale ascends, the higher ranks are discontinued gradually, and ranks of lower tone substituted. This is called a "break." Any number of ranks from three to five may be found in the mixture. This stop is found under several names, *e.g.* Sesquialtera, Cornet, Furniture, etc., and adds great brightness to the full organ.

—— (*Textile Manufac.*) *See* BLENDING.

—— (*Typog.*) When three or more types are used in the composition of a work, it is known by the above term, and involves extra charges.

mm. A common contraction for MILLIMETRE. *See* WEIGHTS AND MEASURES.

M.M.F. (*Elect.*) A contraction for MAGNETO-MOTIVE FORCE (*q.v.*)

Mocha Stone (*Min.*) A synonym for MOSS AGATE (*q.v.*)

Mock *or* **Wild Lead** (*Mining*). A Cornish term for BLENDE (*q.v.*)

Mock Moons *or* **Paraselenæ** (*Meteorol.*) *See* HALOS.

Mock Suns *or* **Parhelia** (*Meteorol.*) *See* HALOS.

Model (*Art*). (1) A standard pattern or object which is to be reproduced. (2) A copy in miniature of an object. (3) A pattern on a small scale of something to be reproduced on a larger scale. (4) A person from whom an artist studies proportions, details, etc., *i.e.* one who sits or poses to an artist.

Modeller (*Pot.*) An artist or craftsman who forms in clay or wax the original model from which Plaster of Paris moulds are subsequently made.

Modelling (*Sculp.*) Constructing with some plastic material, *e.g.* clay or wax, a model which is to be reproduced in a more durable substance, such as marble, wood, etc.

Moderato (*Music*). (1) At a moderate pace. (2) Moderately, *e.g.* *Allegro moderato*, moderately cheerful.

Modern Face (*Typog.*) A book fount of modern character and style. It differs from Old Face or Antique in several respects, *e.g.* in the type being (*a*) not so round, (*b*) the serif being more accentuated, (*c*) the figures ranging both at the top and bottom.

Modes (*Music.*) (1) The ecclesiastical modes consist of fourteen scales, arranged in two classes, Authentic and Plagal. Of these fourteen, two, xi. and xii., are theoretical only, and not practical, xi. (the Authentic) not having a perfect fifth between the first and fifth notes and a perfect fourth between the fifth and eighth notes, and xii. (the Plagal) not having a perfect fourth between the first and fourth notes and a perfect fifth between the fourth and eighth notes, which will be found to be the case in the other twelve modes according as they are Authentic or Plagal. Each Plagal mode is derived from the Authentic, and bears the same name with the prefix Hypo-; it also has the same Final. The Final is the last note of the melody or Canto Fermo. Dr. C. W. Pearce, in his *Composers' Counterpoint* gives the following rule for discovering the mode in which an old melody is written: "If there is no key signature, we may assume that the melody is untransposed, and that the last note is the Final. Next, let us examine the range of the melody, and discover if the Final is approximately the lowest note used; should this be so, the Mode will be Authentic, and its number can be easily ascertained from the Final. But if, on the other hand, the Final occupies an approximately central position in the melodic range, the Mode will be Plagal. If the melody has a key signature, this is a sign that it has undergone transposition; in this case it will be necessary to restore the original pitch by bringing the melody into a range which requires no key signature; then the Final and its position in the range will determine the Mode as before."

TABLE OF THE MODES.

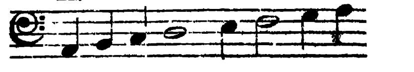
The Final is shown by a semibreve, and the Dominant by a minim. The semitones, of course, always fall between E and F, and between B and C.

AUTHENTIC.

I. DORIAN.

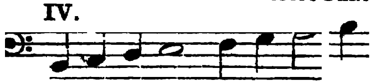
PLAGAL.

II. HYPO-DORIAN.



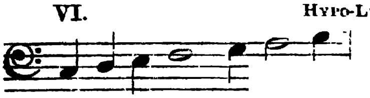
III. PHRYGIAN.

IV. HYPO-PHRYGIAN.



V. LYDIAN.

VI. HYPO-LYDIAN.

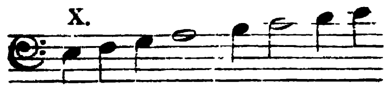


VII. MIXO-LYDIAN.

VIII. HYPO-MIXO-LYDIAN.

IX. ÆOLIAN

X. HYPO-ÆOLIAN



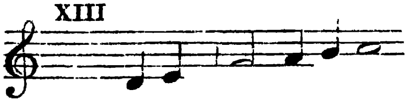
XI. (NOT IN USE.) LOCHRIAN.

[THEORETICAL FINAL B, DOMINANT G.]

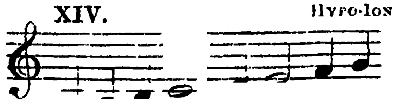
XII. (NOT IN USE.) HYPO-LOCHRIAN.

[THEORETICAL FINAL B, DOMINANT E.]

XIII IONIAN.



XIV. HYPO-IONIAN.

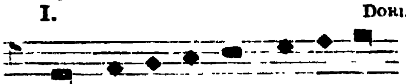


The late Rev. Thomas Helmore, in his "Primer of Plain Song," calls the 11th and 12th Modes respectively the Mixo-Lochrian and Hypo-Mixo-Lochrian. He also gives the following table of the Mode Finals and Dominants :

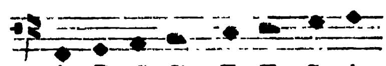
No. of Mode ..	1	2	3	4	5	6	7	8	9	10	13	14
Final	D	D	E	E	F	F	G	G	A	A	C	
Dominant	a	f	c	a	c	a	d	c	e	c	g	

The odd numbers are the Authentic, as pointed out above, and in each of these it will be seen that the Dominant is the fifth note of the mode, and in the even numbers (Plagal) the Dominant is a third below the corresponding Authentic, with this exception : B is never used for a Dominant, C being substituted on every occasion whether Authentic or Plagal. Modes xiii. and xiv. are often spoken of as xi. and xii., owing to the theoretical modes never being used. Tradition says that St. Ambrose authorised the first four Authentic modes, and that later St. Gregory the Great added the corresponding four Plagal in the sixth century, the remaining modes being added later about the end of the eighth or beginning of the ninth century under the auspices of the Emperor Charlemagne. The limited compass of these modes enables the music to be written on four line staves with the (C) and (F) clefs moved to different lines according to the range of the mode, *e.g.*

I. DORIAN.



II. HYPO-DORIAN.



It will be seen that the modern major scale of C is identical with the Ionian Mode (xiii.) (2) The manner of arranging the notes of a scale is called a Mode ; hence we have the Major Mode and the Minor Mode, according to the arranging of the semitone in the lower tetrachord of the scale (*q.v.*)

Modillion (*Architect.*) A projecting bracket in the form of a scroll used at intervals under the corona of the Roman Corinthian cornice. The space between the two modillions is usually equal to about twice the width of the modillions. *See* ANCONES; CONSOLE; ARCHITECTURE, ORDERS OF; CARTOUCH.

MODILLION.

Modulation (*Music*). The act of passing from one key to another. Some writers call a temporary modulation a "transition."

Modulator (*Music*). A chart used in teaching music by the Tonic Sol-fa System (*q.v.*)

Module. A unit of measurement used in classical architecture. It is equal to half the diameter of the shaft immediately above the congé at the base, or, in the case of the Greek Doric Order, half the diameter of the shaft where it rests on the stylobate. The thirty divisions into which the module is divided are known as PARTS or MINUTES. Different values have, however, been given to the module, and it has not always been divided into thirty parts. The lower diameter of the shaft is sometimes taken as a unit; and in this case the module is divided into sixty minutes.

Modulus (*Phys., Eng.*) A coefficient expressing some physical constant of a given material; *e.g.* the Modulus of Elasticity is the Coefficient of Elasticity. *See* ELASTICITY.

Modulus of Elasticity. *See* ELASTICITY.

Modulus of Resilience (*Eng.*) *See* RESILIENCE.

Mohair. A textile material made of the hair of the Angora goat.

Mohair Lustre (*Textile Manufac.*) Dress fabrics. plain woven, consisting of cotton warp and mohair weft.

Moiré Antique (*Silk Manufac.*) A watered effect given to the surface of plain, ribbed, or corded silk fabric by carefully folding the material up the centre and then subjecting it to great pressure between heated cylinders.

Molasses. *See* CANE SUGAR.

Molecular Conductivity (*Chem.*) *See* SOLUTIONS.

—— (*Elect.*) A constant by which the number of gram molecules (*q.v.*) of an electrolyte in a litre of solution must be multiplied in order to give the specific conductivity (*q.v.*) of the solution. Let c be the number of gram molecules, K the specific conductivity, m the molecular conductivity; then $K = mc$.

Molecular Covolume (*Chem.*) *See* MOLECULAR SOLUTION VOLUME.

Molecular Formula (*Chem.*) A formula which merely stands for one molecule of any substance. Thus H_2O is the molecular formula for water.

Molecular Magnet (*Elect.*) A uniformly magnetised body may be conceived as being capable of being broken up into a great number of small magnets, each having the same intensity of magnetisation. If the process of subdivision be carried to its ultimate extent, we obtain a series of magnetised molecules. Theory assumes that these molecules possess permanent magnetism. When a bar of iron is unmagnetised, the molecules lie with their magnetic axes in all directions; but when magnetised, a certain number of the molecules turn in such a manner that their magnetic axes are parallel, and their north poles point in one direction. If only a small number of the molecules are arranged in this manner, the bar is feebly magnetised; but if a great number, then the bar is strongly magnetised. When the number reaches a maximum, the bar is magnetised as strongly as possible, or is SATURATED. *See* SATURATION. If the magnetising force be withdrawn, some of the molecules do not retain their regular arrangement, and the bar loses some of its magnetism. In the case of very soft iron nearly the whole may be lost, while in the case of very hard steel nearly the whole magnetism may be retained. It is to be noticed that this theory is independent of any explanation of the cause of the magnetic properties of the individual molecules.

Molecular Magnetic Rotation. All liquids when placed between the poles of a powerful electro magnet have the power of rotating a ray of polarised light. The rotations of the substance and of water are observed in equal tubes, and the densities of the substance and of water are accurately determined. The molecular magnetic rotation is then given by the formula

$$\frac{r \times M}{d} \div \frac{r' \times M'}{d'}$$

where r and r' are the observed rotations of the substance and water respectively, M and M′ their molecular weights, and d and d' their densities. The constants so determined appear to be of great value; but irregular results are observed with the initial members of homologous series, probably owing to molecular association. The method of applying the constants is best illustrated by examples: (1) The members of a homologous series differ in their M.M.R. by 1·023 for each CH_2. The M.M.R. of pentane being 5·638, that of hexane should be 6·661; observed value, 6·670. (2) To obtain the value for an acid of the fatty series, the M.M.R. of one acid is found, then the method is as follows:

M.M.R. of oenanthylic acid, $C_7H_{14}O_2$	= 7·552
$7 \times 1{\cdot}023$	= 7·161
	0·391

0·391 is called the series constant for the fatty acids. General formula for M.M.R. of fatty acids is:

$$C_nH_{2n}O_2 = 0{\cdot}391 + 1{\cdot}023_n.$$

(3) In a similar way values are deduced for:

(*a*)	The difference of H_2 between a saturated and an unsaturated compound	= 1·112.
E.g.	Ethyl crotonate, 7·589 / Ethyl butyrate, 6·477	Diff. = 1·112
(*b*)	Oxygen in alcoholic hydroxyl	= 0·194
(*c*)	„ „ acid hydroxyl	= 0·137
(*d*)	„ „ carbonyl (CO) group	= 0·261

(4) The method of applying M.M.R. to constitutional questions is illustrated by the following example:

Observed M.M.R. of ethyl crotonate $CH_3 . CH : CH . COOC_2H_5$	7·589
M.M.R. of oxygen in alcoholic hydroxyl (3.*b*)	0·194
Calculated M.M.R. of ethyl hydroxycrotonate $CH_3 . COH : CH . COOC_2H_5$	7·783

Again:

Observed M.M.R. of ethyl hydroxybutyrate $CH_3CHOHCH_2COOC_2H_5$

Difference of H_2 for unsaturation (3.*a*)

Now the series constant of a compound which belongs to two different classes can be found by taking the mean of the series constants for each class. This statement is confirmed by experience. So we have:

Series constant for ester of acetic acid	0·370
Series constant for a ketone	0·375
	2)0·745
	0·373
$6 \times 1{\cdot}023$	= 6·138

Calculated M.M.R. of ethyl acetoacetate
$CH_3CO . CH_2COOC_2H_5 = 6{\cdot}511$
Observed M.M.R. of ethyl acetoacetate
$CH_3CO . CH_2COOC_2H_5 = 6{\cdot}501$
$\overline{{\cdot}010}$

Thus ethyl acetoacetate has the formula $CH_3CO . CH_2 COOC_2H_5$, and not $CH_3C . OH : CHCOOC_2H_5$, which is ethyl hydroxycrotonate. Similarly ethyl ethylacetoacetate has been shown to have the ketone form. All the work on this subject has been done by W. H. Perkin, sen.

Molecular Refractive Power (*Chem.*) The molecular refractive power of a substance is $\frac{n^2-1}{n^2+2}\cdot\frac{M}{d}$, when n is the refractive index of the substance, M its molecular weight, and d its density. Sodium light is used. Brühl, who has done an enormous amount of work on this subject, assigns values for the M.R.P. to the various atoms and groups in a similar way to Perkin for molecular magnetic rotation. His results are often of use in settling questions of constitution. The following example will show the application of the method:

M.R.P.

	Observed.	Calculated for Keto Form.	Calculated for Enol Form.
Methyl acetoacetate	27·20	27·17	28·11
Ethyl acetoacetate	31·99	31·78	32·72

Thus ethyl acetoacetate has the formula $CH_3COCH_2 COOC_2H_5$, and not $CH_3 . C . OH : CH . COOC_2H_4$.

Molecular Rotatory Power (*Chem.*) The rotation ($a°$) of the plane of polarisation of light by a substance of density d, in a tube l decimeters long is observed. The kind of light used is generally the sodium light—the D line in the sodium spectrum. Then the specific rotatory power, denoted by $[a]_D$ is $\frac{a}{l.d.}$. When the substance is a solid it is dissolved in an inactive solvent: in this case the specific rotatory power is $[a]_D = \frac{100a}{p.l.d.}$, where d is the density of the solution, and p is the weight of the substance in 100 grams of the solution. The temperature must be stated, for the value varies with the temperature. The molecular rotatory power is the specific rotatory power multiplied by the molecular weight and divided by 100.

Molecular Solution Volume (*Chem.*) Graube (I) defines this as follows:

$$V_m = \frac{m+l}{d} - \frac{l}{s}$$

when Vm is the molecular solution volume, m the molecular weight of the dissolved substance, l the quantity of the solvent which contains one gram molecule of the substance, d the density of the solution, and s the density of the solvent *in the solution*—the change in volume which occurs on solution being attributed to the solvent. The constants so deduced are supposed to represent the spaces occupied by the molecules of compounds and the atoms of elements more exactly than the constants deduced from the quotients

$$\frac{\text{Molecular Weight}}{\text{Specific Gravity}} \text{ and } \frac{\text{Atomic Weight}}{\text{Specific Gravity}}$$

On these Traube founds a new system of arranging the elements—those of equal solution volumes occurring in the same class. He also shows that molecular solution volumes are of use in deciding when ring formation has occurred. Thus the calculated value of Vm for glycocoll (*q.v.*), on the assumption that it is *not* a ring compound, is 55·7; the observed value is 42·9. As ring formation is assumed to cause diminution of Vm, Traube believes glycocoll to be a ring compound when in solution. When the value for the observed molecular solution volume of a compound is compared with that calculated from the atomic solution volumes of its elements, the former is seen to be larger than the latter, the difference between the two for a series of alcohols at 15° in aqueous solution was found to be fairly constant, and in the mean = 12·4. This constant is called the molecular covolume; it is supposed to represent the space which the molecules have at their disposal for motion of translation. This new constant is found to exist for homogeneous liquids and solids, only for these it has a different value than 12·4, and a method of determining molecular weights is founded on it; but as the values so deduced are not always the correct values, the method is not given here. For further information Traube's work *Raum der Atome* must be consulted.

Molecular Volume (*Chem.*) The quotient $\frac{\text{Molecular Weight}}{\text{Specific Gravity}}$ is called the molecular volume. It should represent the relative volume occupied by a molecule of any given compound; and some regularity exists between the molecular volumes of related substances, but not sufficient regularity to enable any safe conclusions to be drawn as to constitution. For instance, isomeric compounds should have the same molecular volume, and in many cases they have nearly the same molecular volume; but exceptions are of such frequent occurrence as to render a generalisation impossible. The failure of this constant to be of service in constitutional problems is due to the fact that it is not yet known under what conditions the specific gravities of liquid and solid substances are comparable.

Molecular Weight (*Chem.*) As the absolute weight of a molecule of any substance is not known with accuracy, molecular weights are expressed in terms of an arbitrary unit. We shall take as unit the weight of one atom of hydrogen. The definition of molecular weight, therefore, will be: the weight of one molecule of the substance in question, element or compound, when the hydrogen atom is taken as unit of weight. To determine a molecular weight we make use of two further principles: first, Avogadro's Law (*q.v.*); second, the atomicity of the molecule of some standard substance. We shall take hydrogen as the standard substance, and assume that its molecule contains two atoms. We now put

$$\frac{\text{Weight of one litre of any gas}}{\text{Weight of one litre of hydrogen at same temperature and pressure}} = \text{Vapour density of substance.}$$

Let the weight of the molecule of the gas be M, and let there be n molecules of any gas in a litre at the same temperature and pressure; then

$$\frac{M . n}{2n} = \text{Vapour density.}$$

That is, we have always the molecular weight of any gas is twice the vapour density. Molecular weights of gases or substances which can be vapourised are always determined by an application of this rule. For determination of molecular weight by lowering of the freezing point and raising of the boiling point, *see* SOLUTIONS. In chemical measurements quantities are always expressed in terms of molecular

weights. *See* MASS ACTION, SPEED OF REACTIONS, SOLUTIONS.

Molecule (*Chem.*) Imagine a piece of cane sugar submitted to a process of mechanical subdivision carried so far that at last a particle of sugar is obtained which on further division loses the properties of cane sugar; that is, the particle of sugar gives two or more particles which are evidently not sugar. Then this ultimate particle is called a molecule. As we may extend this imaginary process to any compound, it is clear that we can define the molecule of a compound as the smallest particle of a compound that can exist. In the case of an element the molecule is not always the smallest particle that can exist; the atom is the smallest particle of an element that can exist. So we must define the molecule of an element as the smallest particle of an element that can exist in the free state; that is, uncombined with other atoms of the same or different elements. The atom and the molecule appear to be identical in most metals and in the inert gaseous elements (helium, argon, etc.) and in the vapour of certain non-metals at a very high temperature, *e.g.* iodine at 1,500°; these elements are therefore said to have monatomic molecules. Conversely, it may be said that if a substance is proved to have a monatomic molecule, it must be regarded as an element. Neither the absolute size nor absolute weight of a molecule is known with much accuracy; the order of magnitude to which they belong may be gathered from the statement that in one litre of any gas at the ordinary temperature and pressure there are something like eighteen thousand millions of millions of millions of molecules.

Moline (*Her.*) *See under* CROSS.

Moll (*Music*). The German term for Minor, *e.g.* H moll = B minor, the term for major being *Dur*, *e.g.* B. *dur* = B♭ major.

Molto (*Music*). Much: very.

Molybdenite (*Min.*) Sulphide of molybdenum, MoS_2. Molybdenum = 59·1; sulphur = 40·9. Hexagonal. When fresh it is the colour of newly cut lead. It gives a grey streak on paper. Thin lamellæ are flexible, but not elastic. It is soluble in nitric acid. It occurs sparingly in metamorphic rocks in Cornwall, the Caldbeck Fells in Cumberland, Norway, Bohemia, etc.

Molybdenum (*Min.*) This element does not occur native. Its principal native compounds are MOLYBDENITE *and* MOLYBDINE (*q.v.*)

Molybdenum and its Compounds (*Chem.*) Molybdenum, Mo. Atomic weight, 96. Is a white metal which does not change in air at the ordinary temperature, but at 600° it is oxidised to the trioxide, which sublimes; in oxygen at the same temperature it burns; heated in steam at 700°, it gives a mixture of the di- and trioxides; dilute acids do not attack it; nitric acid and hot concentrated sulphuric acid oxidise it. At a high temperature it combines with carbon to form a carbide, Mo_2C. It occurs naturally chiefly as molybdenite, MoS_2, which resembles plumbago. The metal is obtained by reducing any of its oxides or chlorides by heating them in a stream of hydrogen; also by heating the dioxide with sugar charcoal in a carbon crucible in the electric arc (800 ampères and 60 volts) for six minutes; that is, so that the charge near the sides of the crucible is not melted, for the melted metal readily dissolves carbon. This metal belongs to the same group as chromium. It forms an enormous number of compounds. Many oxides are known. The dioxide is obtained pure by fusing ammonium molybdate with potassium carbonate and boron oxide, and extracting with water, when it remains as a brown solid, violet by reflected light. The *trioxide* is a white solid which turns yellow on heating, then melts and sublimes; sparingly soluble in water; with alkalis it yields the molybdates; with strong acids it yields the *molybdenyl salts*, *e.g.* $MoO_2 . SO_4$. It is obtained by heating the native sulphide, contained in a hard glass tube, in a current of air, to such a temperature that the trioxide formed sublimes. Molybdic acid, $H_2MoO_4 . H_2O$, is a yellow solid formed when nitric acid is added to a solution of ammonium molybdate and the mixture allowed to stand. A large number of simple and complex molybdates is known. Ordinary "ammonium molybdate" is probably a double salt derived from trimolybdic acid, $H_6Mo_3O_{12}$, and having the formula $(NH_4)_3H_3Mo_3O_{12}(NH_4)_2H_4Mo_3O_{12}$. It is resolved into its constituents on solution in water. It is a white crystalline solid, obtained by evaporating a solution of the trioxide in ammonia. It is a valuable test for phosphates and arsenates. When an excess of a solution of "ammonium molybdate" acidified with nitric acid is added to a solution of a phosphate, a yellow precipitate of hydrated ammonium phosphomolybdate is formed,

$$(NH_4)_5H . (PO_4)_2 23MoO_3 8H_2O.$$

A similar compound is formed with the arsenates. When the hydrated salt is dried above 130°, it gives ammonium phosphomolybdate, $(NH_4)_3PO_4 12MoO_3$. When the last mentioned compound is treated with aqua regia it forms phosphomolybdic acid, $H_3PO_4 12MoO_3$, a solution of which is an important general reagent for alkaloids. Some compounds of molybdenum and oxygen, which are molybdenum molybdates, have a *blue* colour. The chlorides $MoCl_2$, $MoCl_3$, $MoCl_4$, and $MoCl_5$ are known. The pentachloride is a shining black crystalline solid; melts at 194°; boils at 268°, giving a red vapour; it fumes in air, and is decomposed by water:

$$2MoCl_5 + 3H_2O = MoCl_4 + MoO_3 + 6HCl.$$

The solution becomes blue in air, forming a molybdenyl molybdate, $MoO_2 4MoO_3$. The pentachloride acts as a halogen carrier (*q.v.*) Many oxychlorides are known.—W. H. H.

Molybdic Ochre (*Min.*) A synonym for MOLYBDINE (*q.v.*)

Molybdine (*Min.*) Molybdic oxide, MoO_3. Molybdenum = 65·71; oxygen = 34·29 per cent. Orthorhombic. Usually pulverulent, rarely in fine silky groups. It occurs as a decomposition product of molybdenite, and hence has the same localities.

Moment of a Force (*Phys., etc.*) The product of the amount of a force, by its perpendicular distance from a given point, is called the Moment of the Force about that point. This product is also called TURNING MOMENT *and* TORQUE.

Moment of a Magnet. *See* MAGNET.

Moment of Inertia (*Mech.*) If a particle of mass m be revolving in a circle of radius r, the quantity mr^2 is termed its Moment of Inertia. If a rigid body revolve about any given axis, its Moment of Inertia about that axis is obtained by summing all the separate products $m_1r_1^2$, $m_2r_2^2$, $m_3r_3^2$, etc., where m_1, m_2, etc., are the masses of the separate particles composing the body, and r_1, r_2, etc., are the perpendicular distances of these particles from the axis. The Moments

of Inertia of some solids of common form areas follows, where M is the mass, r the radius :—*Circular Disc:* Axis through centre, $\frac{1}{2}Mr^2$. *Sphere:* Axis through centre, $\frac{2}{5}Mr^2$. *Thin Rod:* Axis through middle, at right angles to rod, $\frac{1}{12}Ml^2$. *Thin Hoop* or *Ring:* Axis through centre, Mr^2. In formulæ for the bending of beams (*see* BEAM) the Moment of Inertia of the cross section is the sum of the products of each element of area into the square of its distance from a given axis. If this axis be through the centre of gravity of the area, and A be this area, we have the Moment of Inertia for a rectangular section equal to $\frac{1}{12}Ah^2$; a triangular section $\frac{1}{18}Ah^2$, and a circular section $\frac{1}{16}Ah^2$: h is the depth of the cross section in the direction along which bending occurs. In beams, I (the Moment of Inertia) must be calculated about the neutral axis (*q.v.*) of the beam, and this may not pass through the centre of gravity of the cross section, but may be at a distance r from it. Then if I_0 be the Moment of Inertia about the axis through the centre of gravity, and I that about the neutral axis, we have $I = I_0 + Ar^2$.

Momentum (*Mech.*) The product of the mass of a body and its velocity. It may be taken as representing the "quantity of motion" of a moving body.

Monad Element (*Chem.*) Same as monovalent element. *See* VALENCY.

Monatomic Molecule (*Chem.*) From Avogadro's Law we have always

$$\text{Vapour density} = \frac{\text{Molecular Weight}}{2}.$$

See MOLECULE. When the vapour densities of mercury, zinc, and cadmium, and iodine at 1,500°, are determined, they give values which are half their atomic weight, from which it is concluded that the atom and molecule of these elements in the gaseous state are identical: they are called monatomic elements. The lowering of the freezing points of many metals, when tin is used as solvent, also yield values for their molecular weights which are identical with their atomic weights. Another kind of evidence is available in the case of mercury and the inert gases argon, helium, etc. The velocity of sound in these gases and in mercury vapour has been found by Kundt's method (*q.v.*) From the observed velocity of sound the ratio of the two specific heats of the gases or mercury vapour can be calculated. *See* VELOCITY OF SOUND. The value for their ratio is 1·66, and this agrees with the value calculated from the kinetic theory of gases for molecules on which no internal work can be done; for instance, no energy of rotation can be imparted to such molecules, nor can they consist of two atoms, for then work could be done in changing their motion about their common centre of gravity; that is, such molecules must consist of single atoms. The ratio of the two specific heats for a gas like hydrogen, which is believed on many chemical grounds to have a diatomic molecule, is 1·41.

Monde (*Her.*) One of the insignia of royalty, consisting of an orb surmounted by a cross, generally pattée. The orb is encircled by a horizontal band, often enriched with gems. *See* CROWN.

Monhydric Alcohol. *See* ALCOHOL.

Monial (*Architect.*) *See* MULLION.

Monk (*Print.*) A black blotch on the printed sheet, caused by a foreign substance in the ink, improper grinding of its materials, or imperfect distribution on the face of the forme

Monkey (*Eng.*) The weight or ram of a pile driver which strikes the head of a PILE (*q.v.*) in order to drive it into the ground.

Monkey Nut. *See* GROUND NUT, PEA NUT.

Monkey Tail (*Carp. and Join.*) A vertical scroll at the end of a handrail.

Mono (*Chem.*) A prefix used in chemistry to denote that the element or group to which it is prefixed occurs only once in the molecule of the compound which bears the name; *e.g.* Monochloracetic acid is acetic acid in which one atom of hydrogen has been replaced by one atom of chlorine.

Monochord (*Sound*). An instrument consisting of a single wire or string stretched on a sounding board between suitable bridges or supports by means of pegs, a spring, or a weight passing over a pulley. Used in experiments on the vibration of strings and in the investigation of the frequency of vibration of other sounding bodies.

Monocotyledones (*Botany*). One of the two subdivisions of the flowering plants. The leaves are parallel veined, the flowers have their parts in threes, and the bundles of the stem are scattered. The subdivision includes the *Liliaceæ*, *Gramineæ*, *Palmæ*, etc.

Monohydric Alcohol (*Chem.*) An alcohol containing only one hydroxyl group. Examples: CH_3CH_2OH . $CH_3 . CHOH . CH_3$. *See* ALCOHOLS.

Monoformin (*Chem.*)

$$\begin{array}{l} CH_2OH \\ | \\ CH_2OH \\ | \\ CH_2OOC.H \end{array}$$

The name given to the ester formed by the union of molecular proportions of glycerine and formic acid, with elimination of one molecule of water. Supposed to be formed when glycerine and oxalic acid are heated together; also when α-chlorhydrin and sodium formate act on each other. On heating the product it yields allyl alcohol—

$$\begin{array}{l} CH_2OH \\ | \\ CHOH \\ | \\ CH_2OOCH \end{array} = \begin{array}{l} CH_2OH \\ | \\ CH \\ \| \\ CH_2 \end{array} + CO_2 + H_2O$$

Heated with water, it gives glycerine and formic acid (*q.v.*)

Monolith (*Architect., etc.*) A column, statue, obelisk, or other feature formed out of a single stone.

Monoperipteral or **Monopteral** (*Architect.*) A species of circular temple in which there is neither wall nor cella, but merely columns supporting a roof. *See* PTERA.

Monophase Generator *and* **Motor** (*Elect. Eng.*) A SINGLE PHASE (*q.v.*) machine. *See* MOTORS *and* DYNAMO.

Monophase Motor (*Elect. Eng.*) *See* MOTORS, ELECTRIC.

Mono Rail (*Civil Eng.*) A rail carried on trestles above the level of the ground. The rolling stock either hangs suspended from the rail, as in the Barmen and Elberfeld Railway in Prussia, or else each vehicle is built like panniers, so that it hangs down on both sides of the rail on which it is balanced, as in the Listowel and Ballybunnion Railway in Ireland. In the latter case side rails are added below the level of the main rail to steady the vehicle: they do not sustain any portion of the load.

Monosaccharoses (*Chem.*) A name given to the sugars containing six carbon atoms. *See* SUGARS

Monose (*Chem.*) A name, rarely used now, for sugars containing six carbon atoms. *See* SUGARS.

Monoses *or* **Monosaccharides** (*Chem.*) *See* CARBOHYDRATES.

Monostyle (*Architect.*) A pillar which consists of a single shaft. *See* CLUSTERED PILLAR.

Monotone (*Music*). The recitation of words on one note.

Mono Triglyph (*Architect.*) An arrangement of the Doric frieze and intercolumniation such that there is only one triglyph between the triglyphs immediately over two adjacent columns. This is the usual arrangement. *See* TRIGLYPH, DI-TRIGYLPH, TRI-TRIGLYPH, ARCHITECTURE, ORDERS OF, *and* ENTABLATURE.

Monovalent Element *or* **Group** (*Chem.*) *See* VALENCY.

Monsoons (*Meteorol.*) Prevailing winds in Southern Asia. North of the Equator they are S.W. winds, lasting from about May to October; and south of the Equator they are N.W. winds during the remainder of the year. The S.W. monsoon is followed during the rest of the year by the N.E. trade wind, and the N.W. monsoon by the S.E. trade wind.

Month, Sidereal (*Astron.*) The time it takes the moon to make her revolution from a given star to the same star again, as seen from the centre of the earth. Its mean value is 27d. 7h. 43m. 11·55s.

——, Synodic (*Astron.*) The time between two successive conjunctions or oppositions, *i.e.* between successive new or full moons. Its mean value is 29d. 12h. 44m. 2·86s.

Monumental Brasses. *See* BRASSES, MONUMENTAL.

Moon (*Astron.*) A satellite of the earth, and to us, ranking next to the sun as the most important of the heavenly bodies. The mean distance from the earth is 238,840 miles; mean diameter, 2,163 miles. The passage of the moon between the earth and the sun, near the nodes, causes eclipses of the sun which are partial, annular, or total, according as the conditions prevail.

Moonstone (*Min.*) A variety of ADULARIA which is a colourless semitransparent variety of Orthoclase Felspar. *See* ORTHOCLASE. Moonstone has a pearly lustre, and is used as an ornamental stone. Suitable specimens come chiefly from Ceylon and other localities in the East Indies.

Moor Cock (*Her.*) A charge: the male or cock bird of red grouse.

Moorish Architecture. This is a branch of Mohammedan architecture, and was originally developed in Northern Africa around Morocco; but the finest examples were produced in Spain, which was under Moorish rule from 710—1492 A.D. The principal features of Moorish work are slender columns; semicircular, horseshoe, and cusped arches, and minarets, which in Spain were replaced by massive towers. The richly coloured interiors were treated with minute surface ornament, tiling, plaster relief, and pierced work, the ornament being usually of geometric type and embodying inscriptions. The most noteworthy examples are the Alhambra at Granada (begun 1248 A.D.), the Alcazars at Seville and Malaga (thirteenth century), the Giralda at Seville, and the Great Mosque at Cordova (begun 786 A.D.)

Moor's Head (*Her.*) A charge representing a negro's head in profile, generally with a pearl ear pendant.

Mopstick Rail (*Join.*) A handrail of circular section.

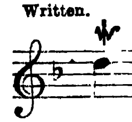
Moraceæ (*Botany*). A Dicotyledon order of trees and shrubs, including the mulberry, fig, hop, etc. This order yields fruits, fibres, rubber, drugs, and timber.

Moraines (*Geol.*) The loose piles of stones and other rock *débris* which are carried outward from the heart of a mountain area by the agency of glaciers. They naturally form three types: (1) Those which have fallen from the slopes above the side of a glacier and form the lateral moraine. (2) Those which find their way to the middle of the surface where two lateral moraines unite into one. (3) The terminal moraine, which represents the *débris* left at the outer end of a glacier. A fourth kind is supposed by some to exist beneath the glacier, and this supposititious material is referred to as the "Moraine Profonde."

Mordants. *See* DYES AND DYEING.

Mordente (*Music*).—Of the musical ornaments or grace notes, this is one of the most important. Mordentes are of two kinds, the Short and the Long, and are written and played as follows:

Written. SHORT MORDENTE. Played.



LONG MORDENTE.

Besides these there is the inverted mordente or pralltriller, which has no upright line through the sign, *e.g.*

Written. Played.

This inverted mordente is also called a "Schneller."

Moreau Marble. *See* ARTIFICIAL STONE.

Morendo (*Music*). Dying away, *i.e.* gradually getting softer and slower.

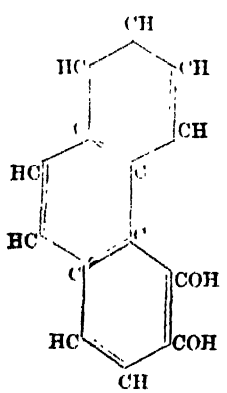
Morion, Morian, *or* **Murrion** (*Arm.*) A Moorish headpiece or helmet copied by the Spaniards about the middle of the sixteenth century, and worn later by other European nations also. The crown of the earlier morions was pointed in shape, the brim, both before and behind, forming a peak, which canted upwards; later the crown was rounded in outline and often surmounted by a crest or comb. The morion was worn as late as Cromwell's time.

Morning Star (*Astron.*) A star which rises just before the sun, in contradistinction to an evening star, which sets just after the sun.

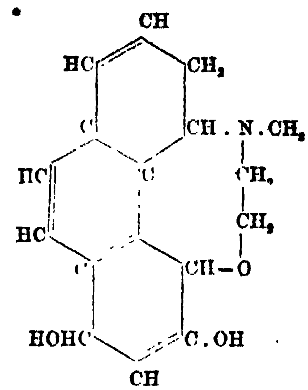
Morocco (*Leather Manufac.*) Tanned goatskins used for furniture and the highest class of bookbinding leather. It was formerly obtained from the African town after which it is named.

Morphine *or* **Morphia** (*Chem.*) An alkaloid. White crystals, needles or prisms, containing one molecule of water of crystallisation; melts with decomposition at 230°; sparingly soluble in water (about 1 in 10,000 at ordinary temperature and 1 in

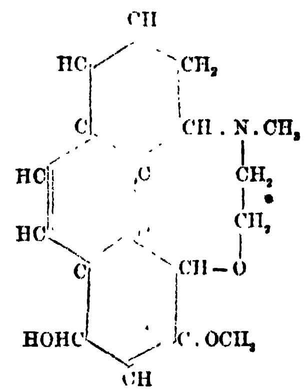
450 boiling); more soluble in alcohol (5 in 100 at ordinary temperature); soluble in warm amyl alcohol; nearly insoluble in ether and benzene. It is lævorotatory. Morphine is a strong base, and forms many salts. The hydrochloride, $B . HCl . 3H_2O$, silky needles, soluble in water; the tartrate, $B_2 . C_4H_6O_6 . 3H_2O$, small white crystals, soluble in water; the acetate, $B . C_2H_4O_2 . 3H_2O$, white crystals, readily soluble in water, are all used in medicine, but the acetate not so much as the other salts, because it loses acetic acid and becomes less soluble. (B stands for morphine.) Morphine occurs in opium, Smyrna-opium containing most of the alkaloid (11·7 to 21·5 per cent.) The opium is thoroughly extracted with warm water, the solution neutralised with calcium carbonate and concentrated; calcium chloride is now added to precipitate meconic acid, and the solution is evaporated to a syrup, when it deposits crystals of morphine and codeine hydrochlorides, which are recrystallised; from the solution of the mixed hydrochlorides ammonia precipitates morphine only. The following reactions are important in the determination of the constitution of morphine. Analysis shows it to have the formula $C_{17}H_{19}NO_3$. It is a phenol because it gives a blue colour with ferric chloride, and combines with caustic soda to form a salt in which one hydrogen is replaced by sodium. It contains another hydroxyl group besides the phenolic one, for it yields both a monoacetyl and a diacetyl derivative with acetic anhydride. The diacetyl morphine is used in medicine under the name heroine. It is a tertiary base because it unites directly with methyl iodide, and the addition product can be converted into a hydroxide. On warming morphine with methyl iodide in presence of sodium ethoxide, codeine (which is methyl morphine) is obtained. Codeine unites directly with methyl iodide to form codeine methiodide, and this compound yields a hydroxide with moist silver oxide. Codeine methyl hydroxide readily loses water, and forms a white crystalline solid called methylmorphimethine, which has the following important reaction: Heated in a sealed tube with acetic anhydride at 160° to 200°, it yields an isomeric compound, and also oxyethyldimethylamine and an acetate of oxymethoxyphenanthrene. The dehydroxyphenanthrene from which the last mentioned compound is derived is called morphol, and it has been synthesised. It has the constitution:



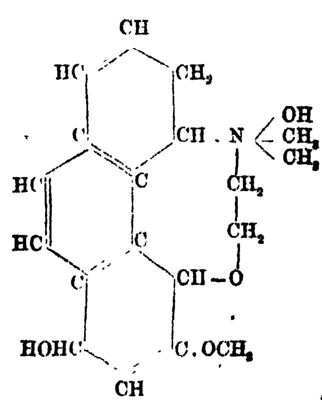
When morphine is heated with zinc dust, phenanthrene is among the products of its decomposition. On these grounds the following formula has been assigned to morphine:



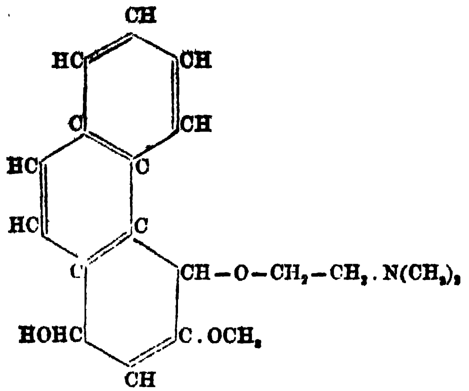
Accordingly the derivatives mentioned will be represented as follows:



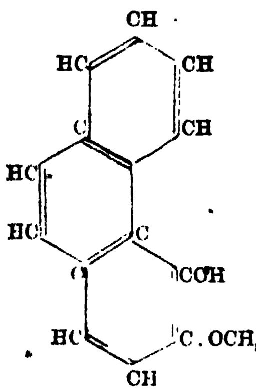
Codeine.



Codeine Methyl Hydroxide.



Methylmorphimethine.



Oxymethoxyphenanthrene (Methylmorphol).

$$HO.CH_2.CH_2.N(CH_3)_2.$$

Oxyethyldimethylamine.

When morphine is heated with concentrated hydrochloric acid it loses one molecule of water, and forms apomorphine, a white amorphous powder which turns green in air; it is used in medicine because it is a powerful emetic. Phosphorus trichloride replaces the alcoholic hydroxyl by chlorine, forming a compound called chlormorphide, $C_{17}H_{18}NO_2Cl$, and this on treatment with water yields two compounds isomeric with morphine, called isomorphine and β-isomorphine; but these compounds have not the narcotic properties of morphine. Morphine acts as a reducing agent, and on this property most of the tests for it are founded, *e.g.* the liberation of iodine from iodic acid. The alkaloid (its salts) are used in medicine for producing sleep and relieving pain; it is very poisonous.—W. H. H.

Morrow Clutch (*Cycles*). A form of friction clutch in which the contact is made by a series of rollers running on slightly inclined teeth, resembling a ratchet wheel. The rollers serve as pauls when the free wheel is driving the cycle; when the pedals are still, the rollers drop back and release the outer ring of the chain wheel.

Morse (*Cost.*) A clasp, often richly engraved, by which a cope is fastened.

Morse Code *or* **Alphabet.** The alphabet in which every letter is represented by a combination of two elementary symbols: in writing, these symbols consist of a dot and a dash; in telegraphic or other signalling the movement of a needle, pointer, flag, etc., to one side represents a dot, and to the other side, a dash. By this means a complete system of transmitting messages can be used with apparatus which is capable of giving two distinct signals only.

Morse Receiver *or* **Recorder** (*Elect. Eng.*) A telegraphic instrument which records the dots and dashes of the Morse Code on a strip of paper which is drawn off a drum. The current received by the instrument acts on an electro magnet which moves an arm provided with a marking point or wheel; this marker comes in contact with the paper strip, and produces a dot or a dash according to the duration of the current.

Mortar. *See* CEMENTS.

Mortar Mill (*Build., etc.*) A grinding and mixing mill for mortar; it consists of two cast iron wheels or rollers, running on the ends of a short horizontal axis which is fixed to a vertical rotating axis. The rollers are thus caused to run round a circular track in a shallow pan in which the lime, sand, etc., are placed. *See* EDGE RUNNER.

Mortice (*Carp.*) A hole, usually rectangular, cut to receive a TENON (*q.v.*) A mortice usually passes right through the piece of wood in which it is cut.

Mortice Chisel (*Carp. and Join.*) A chisel with a very strong blade and a handle adapted for receiving blows from a mallet. Used in cutting a mortice (*q.v.*)

Mortice Gauge (*Carp. and Join.*) A gauge formed by a bar, along which slides a guide or fence which can be fixed at any required point on the bar. Near one end of the latter are two metal points projecting at right angles to the bar; one point is fixed, the other can be adjusted at any required distance from the first one. Used for marking two lines simultaneously, parallel to the edge of a piece of wood, as in setting out a mortice (*q.v.*)

Mortice Machine (*Carp. and Join.*) A machine having a chisel attached to a massive tool holder, which can be raised or depressed by a lever. The tool holder moves vertically in guides attached to the frame of the machine. The wood to be cut rests on a table which can be given a lateral motion by means of a wheel turned by hand; after each stroke or cut of the chisel, the wheel is turned slightly, to move the wood into a suitable position for the next cut to be taken. The machine is now almost universally used for cutting mortices, even in small workshops.

Mortice Wheel (*Eng.*) A gear wheel in which the teeth are formed of wood, each tooth being driven into a mortice or socket in the rim of the wheel; once very common in mill work.

Mortier (*Her.*) A cap of estate, worn by the French Chancellors and Presidents of Parliament; used as a charge in French heraldry.

Mortise (*Carp. and Join.*) *See* MORTICE.

Mosaic (*Architect.*) Inlaid work formed of small pieces, usually cubes, of marble, glass, or other

materials. It is used as a decorative treatment of floors and wall surfaces. *See also* BYZANTINE.

Mosaic Gold (*Chem.*) Stannic sulphide. *See* TIN COMPOUNDS.

Moss Agate (*Min.*) A variety of CHALCEDONY (*q.v.*) containing dendritic forms of Limonite or Pyrolusite, which coat the surface of cracks within the agates. *See also* AGATE.

Mosso (*Music*). Movement.

Motes (*Cotton Manufac.*) Spots on spun yarn due to crushed seed or leaf which has not been freed from the cotton fibre during the spinning processes.

Mother Liquor (*Chem.*) The liquid remaining when a solution of a substance or mixture of substances has been caused to deposit crystals.

Mother of Coal (*Geol.*) *See* COAL.

Mother of Pearl. The inner layer of the shell of many bivalve molluscs, particularly the pearl oyster. This substance is used in ornamental work.

Mother of Vinegar. *See* ACETIC ACID.

Motion (*Lace Manufac.*) One movement of the carriages from back to front or *vice versâ*, like the swing of a pendulum from right to left or *vice versâ*. In most machines it is one revolution of the front shaft.

Motion Bars (*Eng.*) The SLIDE BARS or GUIDE BARS of an engine (*q.v.*)

Motion Block (*Eng.*) A SLIDE BLOCK (*q.v.*)

Motion in Line of Sight (*Astron.*) The motion of bodies in space can be resolved in two directions, either in the line of sight or at right angles to this direction. The former can be measured by the spectroscope.

Motion Work (*Clocks and Watches*). The short train of wheels used between the hour and minute hands to maintain their relative speeds. *See* CANNON PINION.

Motor. A general term for a prime mover or engine; applied especially to electric motors (machines for converting electrical energy into mechanical energy) and to petrol and spirit motors (*q.v.*) Also a contraction for MOTOR CAR.

Motor Boats and Launches.—The term "Motor Boat" is now usually applied to small vessels propelled by an internal combustion engine using petrol or some similar oil or spirit. The engine of such a boat is of some standard type, such as is described under PETROL ENGINE (*q.v.*) In certain cases an engine with a two stroke cycle is employed, as its lower speed is advantageous when the engine is connected directly to the shaft of the propeller. As a petrol engine cannot be reversed when the boat is required to go astern, the propeller is often made "reversible"; the blades can be moved in such a way as to reverse the direction of the screw (*i.e.* from right handed to left handed). The necessary movement is effected by a lever in the boat, connected by a rod to a sleeve on the hub or boss of the propeller. The average size of the boats now in use is about 25 ft. in length, and 5 ft. to 6 ft. in beam, the horse power commonly being from 10 to 15; but boats have already been built of 150 horse power. The Delahaye boat may be quoted as an example. The whole of the engine, working parts, control lever, etc., are carried on a single bed plate, so that, the bottom of the boat having been prepared, it drops into place without elaborate bolting or fitting, and the whole can be easily inspected. The 12 h.p. two cylinder engine has cylinders of 100 mm. bore by 140 mm. stroke, making 1,150 revolutions per minute. The Napier is the best known of the English made engines, and it has already proved as effective on the water as on land. Great interest was evoked in motor boats by the International Race from Calais to Dover on August 8th, 1904. Out of twenty-one starters twenty finished: *Mercedes IV.* (80 h.p.) winning in about a minute over the hour; *Napier* (73 h.p.), some 5½ minutes behind, second. The leaders travelled over 22 knots per hour, and the little *Princesse Elizabeth*, only 30 ft. keel and 45 h.p., easily held the finest and fastest cross Channel boat of the day, the turbine-driven *Queen* (about 300 ft., with 5,000 h.p.), in mid Channel. In October, 1904, in a race between a boat of 40 ft. length and 90 h.p. and another of 37 ft. and 150 h.p., from New York to Albany and back (about 275 miles), the former won, maintaining an average speed for the whole journey of 26·29 miles per hour, a pace excelled by very few "destroyers." These figures seem to indicate that there is a great future for the motor boat.

Motor Cars. The term "Motor Car" is used somewhat loosely, and although in England it is taken to comprise all classes of self propelled goods or passenger vehicles which are adapted to run on ordinary roads, in the United States of America the term is, and has been for many years, employed in connection with tramcars. It is the former or purely British sense that is here adopted, and without attempting a definition that would fully differentiate between what *is* and what *is not* a motor car, it may be briefly stated in general terms that all self propelled vehicles adapted to run, and be steered, on common roads, and to carry either goods or passengers, other than exclusively for their own consumption or guidance, fall within the meaning contemplated. HISTORICAL: The history of the motor car has its origin in the earliest attempts at mechanical traction, and consequently goes back prior to the commencement of the nineteenth century. With these early attempts are associated the names and work of Cugnot (1770), Trevethick (1802), and during a period of phenomenal activity (1825 to 1835) of Hancock, Gurney, Summer, Ogle, and others. The successes achieved by both Hancock and Gurney are such as to suggest that under more favourable circumstances the development of mechanical traction on common roads would have become a matter of steady progress and growth, instead of being doomed to premature extinction, resulting in the almost total loss of the experience and information that had been gained. The railway locomotive, although taking its origin in the same cradle as the steam carriage, proved itself an infant of much more rapid growth. The conditions under which it is required to work being less exacting, success proved to be within more easily attainable reach. From the time of the abandonment of the early steam carriage (about 1840) to that of what may be aptly termed the "Motor Car Renaissance," sporadic efforts were made, and more or less successful results were achieved. Notable amongst these were vehicles by Ricketts (who built a series from about 1858 onwards), Yarrow (1862), Holt (1867), and others. In general, considering the enormously

increased facilities provided by the then modern machine shop, the results achieved during this period were disappointing, especially when compared with the previous efforts thirty years earlier with comparatively crude appliances. It is doubtful whether the weights of engine achieved per horse power was any great advance on Hancock or Gurney, and although in some cases the engine was geared down considerably on to the road wheels as on a modern car, the extent to which this was done (taking into account the slow car speed) was not sufficient to fully realise the advantages of the high speed engine, and thus where gearing was used the advantage obtained was scarcely sufficient to justify its employment. The cars of this period embodied little more than the bare necessities of locomotion, and no attempt was made to build steam carriages in the sense understood by Hancock and Gurney, or motor cars, as they are understood to-day. These sporadic efforts are unimportant historically, as they show no continuity either with the past efforts or with the subsequent history of the development of the modern car. The present era in the history of the motor car was inaugurated by the employment about the year 1885 of the internal combustion engine as the means of propulsion. For this innovation the credit must be given to Gotleib Daimler, who, while adhering to the Otto or four stroke cycle (which had driven all competitors from the field in the gas engine world), succeeded, by adopting high speed, in producing engines of very light weight for the power developed, and so rendering the internal combustion engine suitable for the propulsion of motor vehicles. Of the firms early in the field, the most successful to apply the Daimler engine to the propulsion of the motor car was undoubtedly that of Panhard & Levassor, whose general arrangement of mechanism and system of change gear and transmission, subsequently adopted by many of the leading makers, survives at the present day. The practical solution of the problem by the application of the internal combustion, or, as it is somewhat loosely termed, the "petrol" engine, and the publicity given by the races and competitions that were organised from about the year 1894, had the result of stimulating effort in other directions. Not only did the makers of these cars increase rapidly from year to year, but several firms commenced the manufacture of steam driven cars, in a few cases (notably Serpollet in France, and the "Stanley" or "Locomobile" in the United States of America) as a direct competitor with the light petroleum spirit car; but steam was more generally and successfully employed in cars for heavy traffic with a "tare" of about two tons and upwards. Owing to the development of the industry the term "petrol car" needs definition. Since petrol was the first suitable light petroleum distillate available as a fuel for internal combustion engines, the name became associated with the cars, in contradistinction to steam, gas driven, or electric cars; but really it is a misnomer for petroleum spirit or light hydrocarbon cars. There are now many suitable petroleum spirit fuels for cars propelled by internal combustion engines, but there is a tendency to retain the old title. The limitations of the term petrol instead of petroleum spirit cars are as misleading, as designating cars driven by alcohol motors, "brandy" or "gin" cars, instead of alcohol cars. The Electrical (Accumulator) Motor Car also made its commercial appearance under the stimulating influence of the success achieved by the petroleum spirit vehicle. The claims put forward on behalf of electrical propulsion proved to rest on but slender foundation. The electric accumulator was never able to hold its own against the internal combustion engine or even the steam engine, owing mainly to the cost of up-keep and weight of accumulators necessary per horse power hour. The useful range of the electric vehicle being limited by this latter consideration to about twenty miles out and home, its employment has been confined to short distance work in populous cities. So long as lead oxide is the means of electrical storage there is no prospect of the electrical vehicle seriously improving its position.

TYPES OF MODERN CAR: The various types of modern motor car may be roughly classed as:

MOTOR CYCLES, including all small vehicles built on cycle lines with the motor and frame resting directly on the road wheel axles without "suspension."

Subdivisions:

Motor Bicycles: generally having accommodation for one.

Motor Tricycles: generally arranged with accommodation for two.

Motor Quadricycles: generally arranged with accommodation for two. *See also* MOTOR CYCLES.

MOTOR CARS (so called), including all types of suspended passenger vehicle, and classifiable roughly as follows:

Voiturettes: generally having accommodation for two, with sometimes additional accommodation.

Light Cars: usually built to accommodate four.

Touring Cars: long distance vehicles to accommodate four upwards.

Motor Broughams, *Motor Landaulets*, *Motor Wagonettes*, *etc.* — arranged with accommodation, etc., as their names would indicate. Body work following horse drawn practice.

HEAVY MOTOR VEHICLES, including slow moving vehicles primarily for goods transport usually (at present constructed) upwards of two tons "tare." Types of this class are not as yet fully differentiated; but the steam lorry or dray is at present the principal type.

It may be noted that two types of self-propelled road vehicles, the steam road-roller and the traction engine, are not included in our definition. The popular types of vehicle of the cycle and car classes are subject largely to the influence of fashion, based on, but not altogether proportioned to, the apparent merits of the types of the moment. The "vogue" in motor cycles until about the year 1900 favoured the three wheeled machine, the type then most common being the "De Dion." Since that date the motor bicycle has come into more general use, and is the almost universal one seat machine of to-day, the "quad" and the more modern form of tricycle with fore carriage being the more popular of the two seated arrangements. The most notable effect of fashion in the car class of vehicle has been the vogue until about a year ago (1903) for the rear entrance "tonneau," and the present reaction in favour of the side entrance car. The essential functional elements of a modern petroleum spirit motor car are as follows: Commencing at the fuel tank, we have: (*a*) The VAPOURISER, in which the liquid fuel is vapourised and mingled with air to form an explosive mixture. (*b*) The ENGINE or motor by which the explosive mixture is drawn from the vapouriser, compressed, ignited, expanded, and the products of combustion expelled, and by which as great a proportion as possible of the energy contained in the vapourised fuel is converted into power; and,

subsidiary to the engine, the **Cooler** (or **Radiator**) and **Exhaust Silencer**, by which the waste heat and products from the engine are dissipated and discharged into the atmosphere. (*c*) The **Clutch**, by which the employment of the power of the engine is controlled. (*d*) The **Change Gear**, by which the relation between the speeds of driving and driven mechanism may be accommodated to suit change of gradient (fig. 1). (*e*) **Transmission Train**, by which

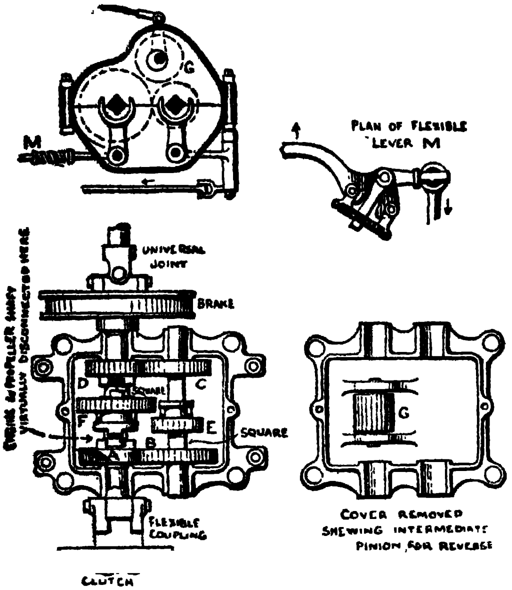


Fig. 1.—The "Argyle" Gear Box.

the power is conveyed to the road wheels (fig. 2). (*f*) The **Tyres**. The functional elements of the steam car are in the main analogous, and to some

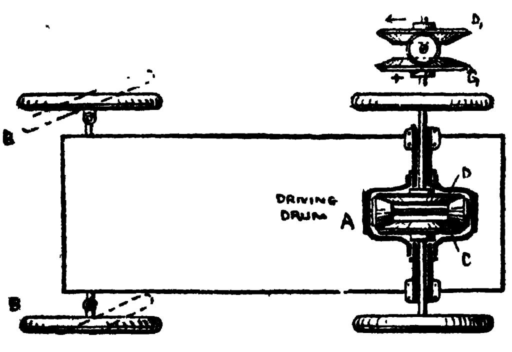

Fig. 2.

extent identical; but the clutch and change gear are dispensed with, the condenser takes the place of the cooler, and the boiler is additional. The vapouriser commonly employed is of the "spray" type, and works on the same principle as the common spray diffuser; it is arranged in the suction pipe of the engine. In another form of vapouriser the petrol is sucked up by numerous wicks into chamber through which the air passes on its way to the motor, and is thereby saturated with vapour. The motor almost universally employed works on the well known "Beau de Rochas" or "Otto" principle, in which the complete cycle of operations occupies four strokes of the piston, these being respectively: (1) suction, during which the admission valve is open; (2) compression, during which the gases taken in on the previous stroke are compressed; (3) the expansion, in which the gases after ignition expand, doing work; and (4) the exhaust, during which the waste products are expelled through an exhaust valve. The number of cylinders in common use varies from one in the cheaper class of car to four in the better class of touring car, and in machines specially built for racing. The advantages of the multicylinder engine are the absence of vibration and the greater uniformity of "torque." The advantages claimed for the single cylinder engine are simplicity and cheapness. Great efforts have been made to produce a balanced engine in which there is no vibration. In the generality of cars the engine is of the vertical type, though in some standard types of car the horizontal engine has been employed, owing to its greater suitability to the design. The coolers or radiators are of various designs, the object being in all cases to present as great a hot surface to the surrounding air as possible. Radiators are sometimes assisted by a fan to blow or suck air over the hot surfaces, and the water circulation is usually maintained by a pump. In some engines direct air cooling has been employed, in which air is blown over gills attached direct to the cylinder. Clutches for the control of the power transmission are of various forms. The majority at the present day are conical clutches, leather faced. An advance on this practice is found in the metal on metal clutches of the "Mercedes," "Lanchester," and "Hele-Shaw" types. The former is a coil clutch and the two latter are conical, the "Hele-Shaw" being an application of the multiple disc (or Weston) principle. The change gear most commonly employed at the present day is that of intermeshing toothed wheels, a series of toothed gears on a sliding sleeve being arranged to successively mesh with a corresponding series on the driven shaft. Another form of gear used by a number of makers is the "Sun and Planet," or epicyclic change gear—a type which offers many advantages, and which probably has a great future before it. There are three main types of power transmission in common use: *the parallel drive*, in which the axes of motor shaft, counter shaft, and road wheels are parallel and connected by ordinary spur gearing or by chains; *the "Panhard" type*, in which the motor shaft is at right angles to the road wheel axle, and the transmission is effected first by a bevel drive on a sprocket shaft, and then by chain drive to the road wheels (fig. 3 and fig. 4); and the *direct right angle drive*, in which the motor is arranged as on the "Panhard" system, but the bevel drive is located on the road wheel axle, and the transmission carried across the suspension by a jointed coupling shaft (fig. 5). A variation in this system is the now well known worm drive. Pneumatic tyres are almost universally used on the passenger types of car. *See* **Tyres**. The only features of a steam car to which special allusion need be made are the petroleum burner and boiler. The petroleum burner in principle is extremely simple, the oil being led through a pipe or tortuous passage heated by the burner itself, whereby the oil is gasified. It then passes to the burner nozzle, where it escapes under pressure, and, mixing with the air necessary for its complete combustion, passes into the burner proper, where the combustion,

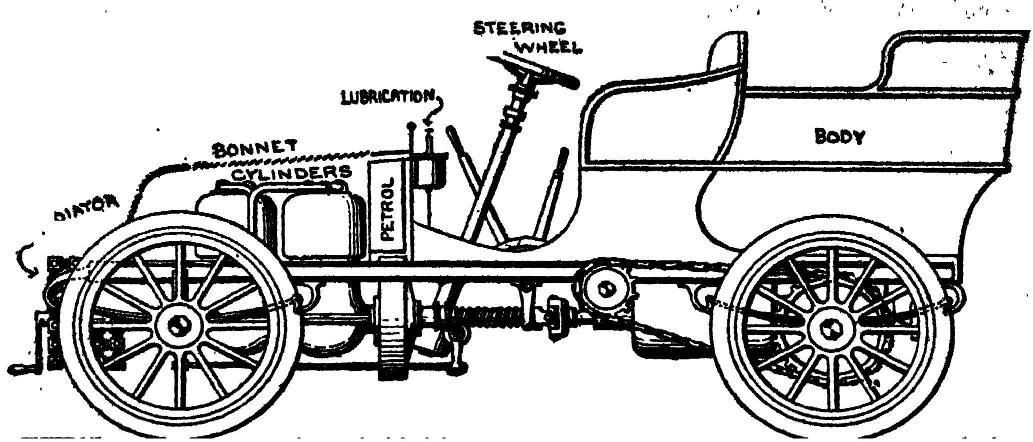

Fig. 3.—Chain Driven Motor Car (Elevation).

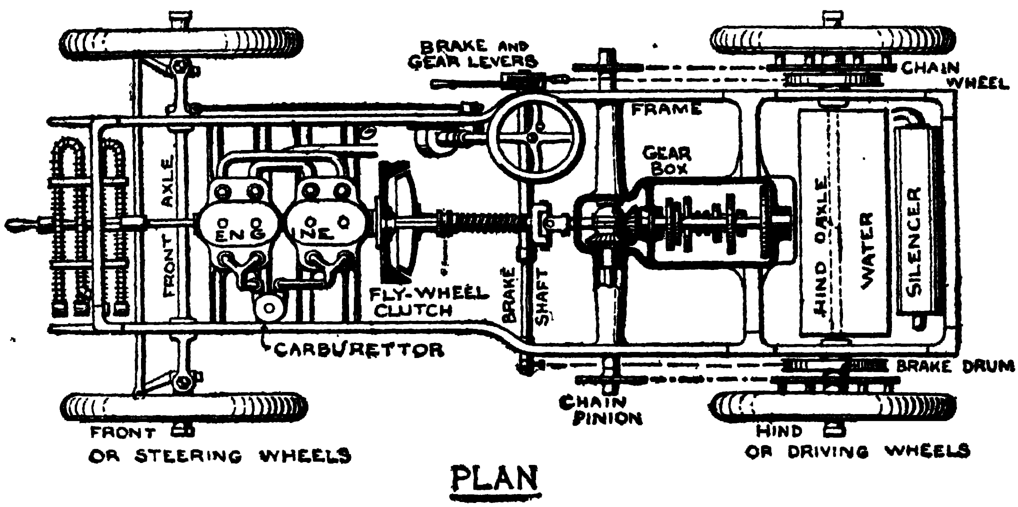

Fig. 4.—Chain Driven Motor Car.

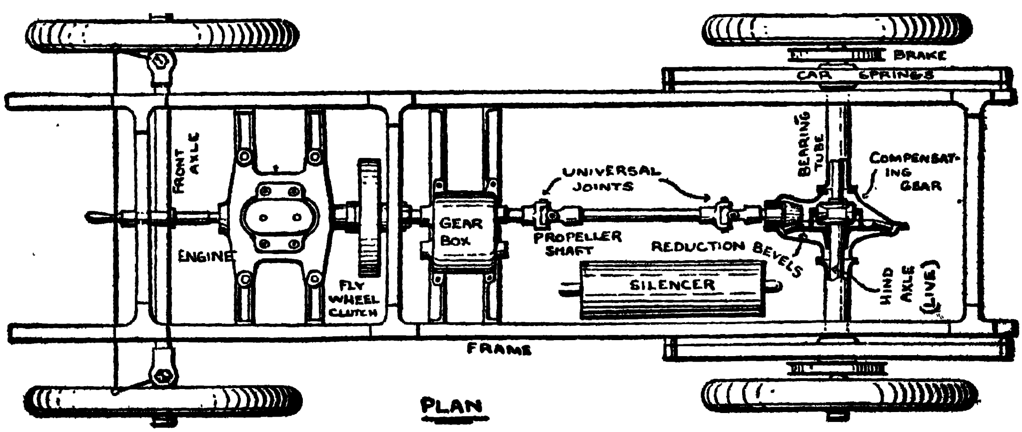

Fig. 5.—A Chainless Motor Car.

if perfect, takes place with a blue flame, as in the ordinary Bunsen or atmospheric gas burner. The steam boilers in use consist in the main of two classes. The ordinary boiler is of the multitubular "*fire tube*" type, and is commonly arranged with vertical tubes, the boiler shell consisting of a cylindrical drum, the ends of the cylinder forming the tube plates. The "Locomobile" boiler may be taken as typical. Special designs of "*water tube*" boiler also are employed. Another boiler of considerable promise is the type known as the "flash" boiler, consisting of a tube of great length and very small capacity, in which the water is converted into steam as fast as it is injected. In these boilers the production of steam is controlled by cutting off or turning on the supply of water to the boiler, simultaneous control being exercised on the burner by which it is heated. The "Serpollet" may be taken as typical of this class, of which it is unquestionably the leading representative. *See* BOILERS. In all types of vehicle an efficient brake is a vital necessity. The only satisfactory forms of brake have metal on metal friction surfaces, an exception being the tyre brakes of slow moving heavy vehicles, where wood blocks are successfully employed. The most generally used classes of brake are the internal and external varieties of band brake on drums fitted to the road wheels; the lever and block brakes, and cone brakes, as fitted to the transmission shaft (fig. 6); also certain disc varieties are sometimes employed. The particular type of brake is not so important as its soundness of design and material. Under the Light Locomotives Act all cars must be fitted with two independent brakes, and this has become the universal practice. Some makers advocate the fitting of a third or reserve brake, but this is quite unnecessary on a well constructed machine.

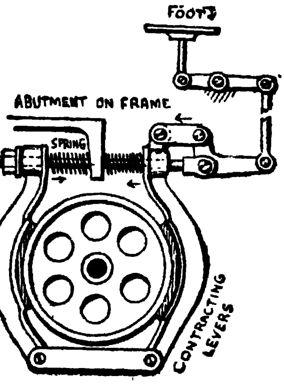

FIG. 6.—THE "ALBION" PROPELLER SHAFT BRAKE.

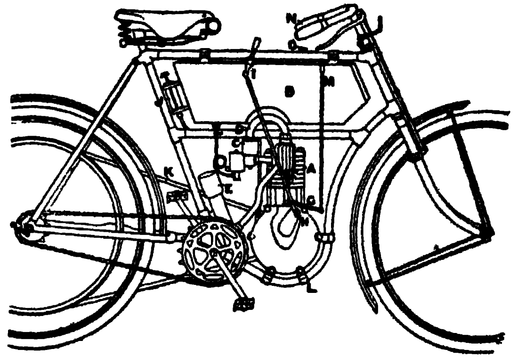
Motor Cycles. The main parts of a typical motor bicycle are clearly shown in the illustration (given by permission of the Temple Press). The frame in this case is somewhat different from that of an ordinary bicycle, but in certain types of machine the form of the latter is adhered to more closely. In all cases, however, the whole structure (frame, wheels, tyres, brake, etc.) is greatly strengthened by means of heavier tubing and lugs, the front forks and head being provided with additional members, if necessary. The back forks are made sufficiently wide to allow of the addition of a driving rim and to provide clearance for the belt K, by which the power is conveyed from the pulley on the axle of the engine to the back wheel. With these exceptions the machine follows the type of the ordinary cycle. The engine itself is a single cylinder petrol engine of ordinary type. *See* PETROL ENGINE. A is the cylinder, bolted to the crank chamber, which is secured by lugs L to the frame. Above the engine is placed a case B, which contains a tank for the petrol, another for lubricating oil, and a compartment for the accumulators and induction coil. Petrol flows from the tank through a tube of narrow bore to the SPRAY CARBURETTOR (*q.v.*) C;



MOTOR CYCLE.

M, Rod for lifting exhaust valve.
N, Handle Switch.
O, Plug Switch.

from this tube the gas flows through the pipe D, and enters the cylinder by an INLET VALVE (not visible in the figure). The exhaust gases (products of combustion) leave the cylinder by an EXHAUST VALVE in the chamber F, and pass through another pipe to the SILENCER E. The exhaust valve can be lifted when required by a lever G, actuated by a rod M. The current flowing through the primary of the induction coil is interrupted by a CONTACT BREAKER in the chamber H; this contact breaker is actuated by the HALF SPEED SHAFT. The time at which the spark occurs can be controlled within certain limits by "advancing the spark"; this operation is effected by turning the contact breaker through an angle by means of the lever and rod I. Lubricating oil is supplied to the engine when required by means of a small pump J, worked by hand. The engine can be stopped by cutting off the current entirely; for this purpose two SWITCHES are included in the primary circuit: one is usually contained in a handle N of the machine, and is operated by turning the handle half round; the other is a PLUG SWITCH O, which is closed by the insertion of a small brass plug, easily carried in the pocket when the rider has dismounted, and wishes to ensure that the current from the accumulators is not wasted or the current improperly started. The details and method of action of the engine are dealt with under GAS ENGINE, OIL ENGINE, and PETROL ENGINE; but the principles involved may be summarised as follows:—A supply of petrol sufficient for one charge is drawn into the CARBURETTOR C, where it is volatilised and mixed with air to form an explosive vapour, and is drawn into the cylinder chamber, which it fills as the piston descends. On the piston rising both valves close, and, there being no escape, the "mixture" (as the air and petrol vapour is termed) is highly compressed, *i.e.* to a third or quarter of its original volume. At this point it is fired by the SPARKING PLUG, the vital "heart" of the machine. This emits the spark which fires the

charge (internal explosion), and gives motion to the whole machine by the explosive power thereby exercised. The sparking plug is a porcelain cylinder or tube surrounded by a metal sleeve nut, which makes a gas tight joint; the connecting wire passes through the plug, the sparking joint being within the explosion chamber. At the outer or flat end the end of the wire is bent at right angles, and at $\frac{1}{32}$ of an inch from it is a corresponding wire connected with the metal shell, and therefore with the frame of the machine which is used to convey the return circuit. The spark jumps over the small space between the joints. On the side of the engine opposite to the pulley is a short shaft, the half speed shaft, rotating at one half the speed of the crank shaft. This operates the exhaust valve (or exhaust and inlet valves) and also the contact breaker, an electrical device which is made in various patterns, but mainly of either WIPE or MAKE AND BREAK contact. It consists of a very small, light, flexible steel spring. Midway there is a tiny platinum disc; on the other end either a V projection or other device to engage the eccentric of the revolving cam. Above the disc is a corresponding platinum stud at the end of a screw, which forms the terminal of the electric wire. The spring vibrates at high speed; each time the discs are separated the current is broken, and the spark thereby produced within the cylinder. When the explosion has driven the piston to the bottom of the cylinder, the inlet valve closes, and the exhaust valve opens. The spent gas is swept out as the piston rises. The chamber is now empty, the piston descends, the exhaust valve closes, the inlet valve opens, and the next charge is sucked through the carburettor into the chamber. The piston now rises again, and the gas is compressed; the charge is fired, and so the process goes on at the high rate of 1,500 to 2,000 revolutions of the engine per minute—two revolutions (four motions) to each explosion. The spent gas passes from the exhaust valve into the silencer, a chamber which serves to deaden the sound. Without this device—*i.e.* with a "free port" to the exhaust valve—the noise created by the explosions would be deafening. There are many forms of silencer: in most of them the burnt gas is discharged close to the ground. MAGNETO IGNITION is an alternative system of firing the charge; the current is produced from the engine by a small magneto machine (a simple form of dynamo with permanent field magnets). A special form of sparking plug is used in the "low tension" system, as this method of ignition is termed. The device causes noise and friction, and uses up energy; but neither coil nor battery is needed. HORSE POWER (expressed h.p.) varies considerably: 1¾ h.p. is the standard for ordinary roadster touring single bicycles, but 2 to 2½ and even higher powers are used by expert riders. High power means great speed, more danger, and greater cost. The TRICARS, where permanent provision is made for a passenger, and perhaps luggage, generally have 3 h.p. On the path, for pacing in races, French riders use 10, 12, and even 14 h.p. on a single or tandem bicycle. The ENGINE, although generally vertical, is sometimes placed at various angles, or even horizontally, as the maker considers most effective. The DRIVING POWER may be communicated in several ways: (1) Belt. (2) Chain. (3) Gear. The belt is either: (*a*) flat leather strap; (*b*) twisted hide, which can be further twisted to tighten; or (*c*) a V built up and flat bottomed, so as to better grip the V or U pulley. The CHAIN is not nearly so much used as the belt, but is increasing in favour. The GEAR DRIVE is being introduced in some cases: the power is transmitted from the engine through gearing somewhat analogous to that used in motor cars. GEARING DOWN: Owing to the high speed of the engine, the driving is from a small pulley on the motor axle to a pulley four, five, or six times the size, otherwise the speed would be too great. In racers the ratio is reduced from one to two and a half. Some machines (such as the Bat) have no pedals, and the rider is dependent entirely on his engine. In most cases, however, pedals (always "free wheel") are employed, and are useful in helping the motor up a stiff hill, or for exercise when the rider has become cold or cramped. Lubrication is effected by the small pump J, above mentioned, placed within easy reach of the rider. Only a special and heavy product of vaseline for air cooled motors can be used; an ordinary oil would be burnt up by the great heat. A few strokes of the pump force the lubricant into the crank case and other required points. The electric current should be frequently tested and the battery recharged, as if it runs out the rider is helpless. Indeed, the three non-mechanical essentials—the battery, the petrol supply, and the lubricant—should be carefully watched. VIBRATION is the great drawback of motor cycling. A much larger and easier saddle is required than in the case of the ordinary cycle. Spring saddle pillars have been introduced; in the Bat the seat pillar is isolated from the machine by coil springs, with resultant comfort to the rider. The handle bars communicate great vibration, to obviate which the Quadrant Company fit a most effective double fork, which absorbs a great portion of the vibration, the consequence being that the arms and hands do not get tired, as with a rigid machine. Various attempts have been made to produce a detachable motor which can be fitted to an ordinary cycle. One of the latest is due to W. S. Simpson, and can, with but little alteration, be added to existing bicycles. The motor and its equipment are carried on a frame on tubular shafts, which extend from the axle of the rear wheel backwards, looping round the wheel, with a second loop extending towards the ground; this latter carries the engine, which is also supported by a castor wheel at the rear. As the motor possesses a certain amount of vertical "play," it rides easily behind the machine, which it propels by a chain. Extra large petrol tanks (capacity for 100 miles) are carried on the shafts. Control from the handle bar is effected by Bowden wire connections, and any type of motor may be used. The machine answers capitally, and is of particular value to ladies, as there is no extra machinery, oil, heat, or complication to interfere with the dress. Vibration is almost annulled, and the motor can be readily detached when required. ADDITIONAL ATTACHMENTS TO MOTOR CYCLES: The average motor cycle is strong enough to carry an extra load or passenger. There are three principal forms of attachment: (1) TRAILER: A small two wheeled "bath chair" wicker seat trailed behind the motor; it is practically extinct. (2) SIDECAR, with one wheel, the other side being attached to the motor cycle frame; it brings the passenger alongside the driver, and is much the most companionable form. (3) FORECAR: The front wheel of the bicycle is removed, and the steering pillar fits on behind the axle of a light two wheeled chair seat, which is secured by side tubes, etc., to the bicycle. It gives a seat immediately in front of the driver, and is the

most popular and effective form of passenger device. OTHER FORMS OF MOTOR CYCLE OR CYCLE CARS: Correctly speaking, a cycle is "a wheeled vehicle propelled by the action of the feet," and the motor merely an addition thereto; but the tendency is to make motor "cycles" without pedals, more particularly tricycles and quads (four wheelers). Many of these are built with permanent seats for a passenger. The arrangements of the motor tricycle and quadricycle differ from the bicycle chiefly in the following points: (1) The engine is fixed close to the back axle, to which the power is transmitted from the crank shaft by a train of gear wheels. (2) The cylinder is usually "water cooled" (*q.v.*) These arrangements introduce extra complications, which cause a well made motor cycle with three or four wheels to be almost as elaborate in its mechanism, and therefore nearly as expensive, as a small light car. On this account the distinction between the car and the motor cycle now tends to become more marked than ever. The tricycle and quadricycle are disappearing, having been displaced by the TRICAR. This type, a direct development of the motor bicycle (as distinguished from the motor tricycle), is coming more and more into favour. The best known, and practically the originator of the type, is the Trimo. It retains, however, the motor bicycle type as a basis (pedals being retained), and to this form (or that of a tricycle) it can be restored with a little alteration. In the more elaborate patterns the body is hung on C carriage springs. A free engine is fitted with two speeds and a clutch, which can be slipped after the rider and passenger are mounted, thereby starting the machine.—H. H. G.

Motor Dynamo (*Elect. Eng.*) An electric motor combined with a dynamo. The former is actuated by an electric current and drives the dynamo, which produces a second current differing from the first in voltage, etc. An alternating current may be changed to a direct current, or *vice versâ*, or a high voltage continuous current transformed to a low voltage one by this means.

Motor—Oil, Petrol, Spirit (*Eng.*) *See* PETROL ENGINE, *etc.*

Motors, Electric. The direct or alternating current dynamo can, instead of converting mechanical into electrical energy, perform the reverse process without any change in its mechanical construction or electrical connections. It is then termed an ELECTROMOTOR. Rotatory motion due to electromagnetic action was first produced by Faraday in 1831, closely followed by Salvatore del Negro and Pixii. Other pioneers in direct current motor development were Jacobi, Pacinotti, Gramme, and Siemens. In 1873 the first public electric power transmission scheme was shown at the Vienna Exhibition, when two similar Gramme machines were used—one as the generator, the other as the motor, the distance between the two being a bare third of a mile. The first alternating current polyphase motor was made by Bailey in 1879, Deprez and Ferraris almost simultaneously following up this method of power conversion. Whenever two sets of lines of force (*q.v.*) or separately generated magnetic fields occupy a common zone, a tendency exists for the lines to so alter their paths that as many lines as possible shall coincide in direction, each field being therefore distorted from its natural arrangement. This mutual distortion sets up a recovering stress which is imparted to the magnet or current carrying coil producing the field, the effect of which is a tendency to motion in the material substance employed. When one or both of the fields are due to a current flowing in a conductor, the tendency to motion of each wire is at right angles to the direction of the field acting on it, and also to the direction of flow of current in it. A coil (fig. 1), pivoted on axis XY, having a

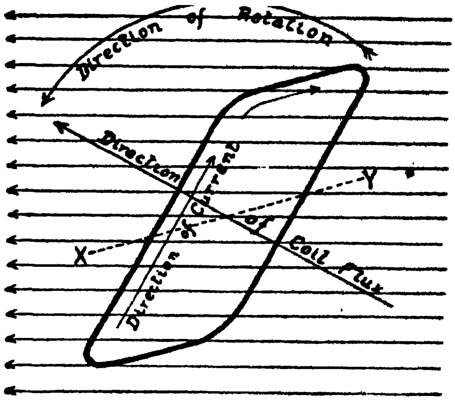

FIG. 1.

current flowing round it in the direction shown, and placed in a magnetic field shown by the long straight arrows, will rotate in the direction of the large curved arrow until the lines of force developed by the current in the coil coincide with the direction of the field. If the current direction were reversed, the coil, if moved out of its position of equilibrium, would tend to move through a semicircle to a fresh position of rest. A direct current motor essentially consists of a collection of such coils arranged cylindrically and provided with a current reverser or COMMUTATOR, the brushes being so placed that all the current carrying coils assist each other in producing continuous rotatory motion. During such motion the conductors cut the lines of force of the field, producing a counter electromotive force, and constancy of rotation is obtained when this back electromotive force, plus the volts lost in armature resistance, equal the voltage of supply to the armature. The commercial efficiency of a motor is the ratio of the mechanical output ($= 2\pi n\text{T}$ foot pounds per minute, where n = revolutions per minute, T = TORQUE (*q.v.*) or twist on the armature in pound feet) to the electrical in-put ($= \frac{\text{CV}}{746}$, where C = current supplied to the motor, V = voltage of supply). This ratio is usually expressed as a percentage. The full load efficiency of direct or alternating current motors varies from 95 to 70 per cent., according to size, speed, and condition of working. The losses are due to friction of bearings, and, in some types, of brushes; air friction or "windage"; magnetic hysteresis (*q.v.*) in the iron parts; local eddy or Foucault currents (*q.v.*) in the conductors, and heat losses on the conductors. The torque is equal to the product of the average thrust in pounds on the armature conductors and the radius of these conductors in feet from the centre of the shaft. Modern continuous current motors, precisely like continuous current dynamos, have revolving armatures and fixed fields. The field may be in series or shunt to the armature, and compound or

differentially wound motors are sometimes, though not often, used where great constancy of speed is desired. *See* DYNAMOS. Where a high starting torque is required (*e.g.* in traction work) a series motor is employed. On tramway systems the modern motor is a four pole series motor wound for 500 volt circuits and thoroughly waterproofed. A series motor will not run at constant speed with varying load, and must be continually regulated by a "controller" or hand operated switch resistance. A shunt motor, if of small armature resistance and strong field, will give an almost constant speed with varying loads, and hence needs little manual control beyond starting and stopping. In starting a series or shunt motor a STEPPED RESISTANCE (*q.v.*) must be placed in series with the armature to avoid an excessive rush of current. Reference is made in the article on dynamos to the necessity of giving a forward lead to the brushes. In a motor the lead is backward, as the armature current flows in an opposite direction with respect to the field to that in a dynamo. Modern practice is in favour of using multipolar in preference to bipolar machines, except for very small outputs. Two alternators cannot be run as generators in series unless mechanically coupled, for if they become ever so slightly out of phase the resulting current retards the lagging machine by throwing work into it, and accelerates the leading one, until they fall into complete opposition of phase, one driving the other; hence one becomes a generator, the other a motor. There is no difference in the construction of a synchronous alternating current generator and motor, these being reversible simply by the conditions of loading. This applies alike to polyphase and single phase alternators. The description of these alternators (*see* DYNAMO) therefore applies to such motors. In order to connect this type of motor to an alternating current supply it must be "synchronised," *i.e.* it must not be switched on to the mains until its frequency, terminal voltage, and phase are identical with that of the supply. A separate direct current supply is necessary to excite the field magnets of the alternator unless a special commutating device is mounted on the shaft, whereby a portion of the current thus rectified can be shunted through the field, as in the case of a rotary converter. Let a ring of soft iron be continuously wound with a coil (fig. 2), having four tappings (or points at which it is connected to external conductors), and two independent alternating currents, of the same frequency, but differing in phase by a quarter period, be led into the winding by tappings AB and CD respectively. When circuit AB has its maximum current, that in CD will be *nil*. At this instant a zone of magnetism is set up of general direction CD. A quarter period later a zone is set up of direction AB. Between these times one zone dies out as the current diminishes, the other zone increasing. These combine to form a resultant zone shifting in direction from CD to AB. This continues throughout the period, and we get a rotating field due to the stationary or STATOR windings. If, now, a bundle of short circuited conductors be placed within this ring, currents are induced due to the cutting of conductors by the lines of force. These currents in their turn set up magnetic fields. If the currents lag behind the impressed electromotive forces due to the cutting, the induced fields lag behind the inducing field. There will be a constant effort of the induced field to align itself with the inducing field, which effort is transmitted to the substance of the conductors, and rotation ensues. This is the principle of the POLYPHASE INDUCTION MOTOR, and can be applied to any number of phases. In large commercial machines the revolving (or rotor) windings are usually grouped systematically, and have facilities for connection to external resistances for use in starting. The same principle may be applied to single phase currents by placing circuits AB, CD, in parallel on the supply mains, but feeding, say, AB through a non-inductive resistance and CD through a highly inductive coil. The phase CD is thereby retarded behind that of AB, and a rotating field produced. Full speed having been obtained, this starting device or PHASE SPLITTER may be cut out of action, the machine continuing running by its internal reactions. To increase the effect the rotor conductors are embedded in iron. In order to ensure efficiency, the iron employed both in stator and rotor must be of the softest description and well laminated, and the gap between the fixed and rotating parts must be as small as practicable. The efficiency of these machines is not so high as that of synchronous motors of the same output, as, owing to the high inductance of the iron circuits, heavy lagging currents occur, causing much heat waste. A recent type of alternate current motor is the repulsion motor, which is similar in construction to a direct current motor, with the exception that the field is made of laminated iron having an alternating current passed through it from the mains. The brushes, which are placed at an angle from their neutral position, are short circuited. The closed circuit thus formed produces a magnetic flux at an angle to the main flux of the field. By the effort of this flux to align itself with that of the field, the conductors under the brush are dragged round, and as fresh conductors continually come into position the rotation is continuous. When the motor is up to speed the brushes may be lifted, the motor then running as a single phase induction machine. The same effect is produced by "shading" part of the (laminated) polar projections of an alternating current electromagnet by sheets of copper, producing a lag of phase in this portion of the field due to the eddy currents, and so producing a shifting zone of magnetisation. An ordinary induction machine rotor is used.—J. A. S.

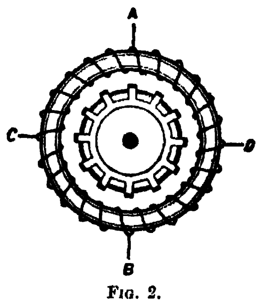

FIG. 2.

Motor Spirit. *See* PETROL, *etc.*

Mottled Soaps. A domestic soap, mostly of a common grade, which possesses a mottled appearance not unlike marble, such as white with blue veins or grey with darker grey veins. Mottled soaps are now not much used in England, but large quantities are exported to the Colonies and elsewhere.

Motto (*Her.*) A pithy sentence or even a single word appended to an escutcheon. Sometimes it is a punning device; *e.g.* the motto of the Vernon Harcourts is *Ver non semper viret.*

Mould. The matrix in which an object is cast, and from which it receives its form. *See* CAST; LOST WAX PROCESS.

Mould (*Carp. and Join.*) A thin piece of wood or zinc cut to shape (profile), serving as a template (*q.v.*) or guide in cutting scrolls, handrails, or other curved work.

—— (*Foundry*). The hollow space into which liquid metal is poured in order to produce a casting. Moulds are made of sand and loam for iron, steel, or brass castings; but they may be of some metal when castings are required in lead, pewter, or similar fusible alloys.

—— (*Paper Manufac.*) A wire cloth fixed to a wooden frame, used for making paper by hand.

—— (*Plast.*) A template or piece of zinc cut out the reverse of the profile of a moulding to be run in plaster.

Moulders (*Foundry*). The workmen in the foundry who make the moulds, cores, etc., by means of the patterns and core boxes supplied by the pattern makers.

Mould, Formation of (*Geol.*) This is due almost entirely to the combined effects arising from the action of various chemical, organic, and physical changes affecting rocks at a short distance below the surface of the land. One of the most potent causes of change is that set up by bacteria, which convert dead vegetable matter into the humus acids, solutions of which, in their turn, dissolve many of the rock constituents, and thus help to convert the residue to a pliable state capable of easy transport by the wind. Worms may perform a share of the work.

Moulding (*Architect., etc.*) A generic term applied to the various contours or sectional outlines of such features as string courses, cornices, plinths, bases, capitals, door and window jambs, arches, etc. *See* ASTRAGAL, BEAD, TORUS, FILLET, CYMA, CAVETTO, OVOLO, SCOTIA, BOWTELL, ROLL MOULDING, *and* SCROLL MOULDING.

—— (*Foundry*). The formation of MOULDS (*q.v.*) This operation is carried on either by the use of patterns (*q.v.*) or in certain cases by shaping or striking the mould in loam by means of LOAM BOARDS (*q.v.*)

Moulding Box. The iron frame holding the sand in which moulds are formed; often termed a FLASK.

Moulding Cutter (*Carp.*) A revolving cutter, whose profile is formed into a shape the reverse of a moulding which has to be cut. It is attached to a spindle rotated at a high speed by power.

Moulding Letters. Metal letters used for producing the mould for casting letters on name plates, etc., instead of actually cutting the letters on the pattern.

Moulding Machine (*Foundry*). Mechanism used for producing comparatively simple moulds, of which a number are required all alike. Moulds for cast wheels are conveniently made by means of moulding machines, and a complete pattern is not required.

Mound (*Her.*) *See* MONDE.

Mount (*Her.*) A tump or hillock at the base of a shield, generally vert.

Mountain Chains. A geographical term that is often applied to any group of mountains which happen to occur more or less in line with each other, whether they are due to terrestrial uplifts formed under the same conditions or not. Most typical mountain chains are, like the Andes, great surface wrinkles, primarily due to movements of the Earth's crust, and are correlative to adjacent zones of depression.

Mountain Cork (*Min.*) A loose porous variety of Amphibole (*q.v.*) It is often so light as to float on water; it occurs in fissures in rocks which have had some of their ferromagnesian silicates decomposed.

Mountain Meal. A synonym for Kieselguhr. *See* DIATOM.

Mountain Railways (*Civil Eng.*) A term properly restricted to lines on which the adhesion of the locomotive wheels to the rails is insufficient to propel the train, necessitating the use of other means. These other means are usually a CABLE (*q.v.*), some form of RACK, or a central rail gripped by horizontal wheels on the locomotive, as in the FELL RAILWAY (Mont Cenis, etc.) The rack systems include the LADDER RACK, formed of bars (Mount Washington, U.S.A.); LOCKER RACK (Pilatus), in which the teeth are on two sides of a central rail and the toothed wheels gearing with them are horizontal; FLAT BAR RACK (St. Eilero, Italy); and ABT RACK, with two (or three) flat racks side by side, their teeth being arranged stepwise, so as not to come in line with each other (Hartz Mountain Railway). The Abt Rack appears to be the most satisfactory of all these systems. *See also* RAILWAYS.

Mountings (*Eng.*) A general term for the small parts that are added to a machine, etc., when the main parts are complete; especially the fittings added to a boiler after the shell leaves the hands of the boilermakers.

Mount Sorel Granite. *See* BUILDING STONES.

Mounture (*Silk Manufac.*) A figured harness composed of cotton or linen thread, built up to and connected with the Jacquard machine in such a way as to operate on the warp threads either singly or by sections.

Mouse Mill (*Elect.*) A simple form of electrical induction machine; used in charging the needle of a quadrant electrometer.

Mouse Roller (*Print.*) A small roller connected with the inking arrangements of printing machines of the Minerva pattern; used for distributing the ink evenly on the disc.

Mouthpiece (*Music*). That part of wind instruments which is applied to the lips. There are three kinds: (1) reed, as in the clarionet or bassoon; (2) cupped, as in the trumpet; (3) a hole, as in the flute. *See* MUSICAL INSTRUMENTS (WIND).

Movable (*Typog.*) A term applied to type in order to distinguish it from stereotype, electrotype, etc.

Movable Bridges (*Civil Eng.*) These embrace FLOATING, SWING, TRAVERSING, LIFT, and BASCULE BRIDGES (*q.v.*)

Movable Do (*Music*). A term applied to the Tonic Sol-Fa system, in which the keynote is always called Do. The movable Do is the essential characteristic of the modern or Tonic Sol-Fa system, as distinguished from the older system, in which the term Do is applied only to the note C (Fixed Do). *See also* TONIC SOL-FA.

Movable Weirs (*Civil Eng.*) Weirs which can be adjusted in height or entirely removed during floods, etc. They include FRAME, SHUTTER, and DRUM WEIRS (*q.v.*)

Movement (*Music*). A section of a larger work, such as a sonata. Each section or movement is complete in itself as to form, although each movement should have a connection with the whole work.

MS. An abbreviation of the word "manuscript." MS. is generally termed "copy" (*q.v.*) by printers.

M.S. (*Music*). The left hand; the letters standing for the Italian *Man Sinistra*. The equivalent in English is L.H., and in French M.G (*Main Gauche*).

MSS. An abbreviation of the word "manuscripts."

Mucic Acid (*Chem.*), COOH . CHOH . CHOH . CHOH . CHOH . COOH. Small white rhombic prisms; melts with decomposition at 210°: sparingly soluble in cold water; more soluble in hot water; insoluble in alcohol. Prolonged boiling with water converts it into a soluble lactone (*q.v.*) (paramucic acid). Heated with pyridine it is converted into a stereoisomeric acid (allomucic acid). Heated with a mixture of concentrated hydrochloric and hydrobromic acids it yields α, α'-furfurane dicarboxylic acid,

$$\begin{array}{l} CHOH \,.\, CHOH \,.\, COOH \\ | \\ CHOH \,.\, CHOH \,.\, COOH \end{array} = \begin{array}{l} CH = C \,.\, COOH \\ | \qquad\quad \rangle O \\ CH = C \,.\, COOH \end{array} + 3H_2O$$

which loses CO_2 on heating, forming pyromucic acid, $\begin{array}{l} CH = C \,.\, COOH \\ | \qquad \rangle O \\ CH = CH \end{array}$. Ammonium mucate on heating yields pyrrol, $\begin{array}{l} CH = CH \\ | \qquad \rangle NH \\ CH = CH \end{array}$. Heated with barium sulphide, mucic acid yields α-thiophene carboxylic acid, $\begin{array}{l} CH = C.COOH \\ | \qquad \rangle S \\ CH = CH \end{array}$.

The acid is obtained by oxidation of many kinds of gum, and by oxidation of dulcite, galactose, and lactose. The formula shows the acid to contain four asymmetric carbon atoms; it should exist therefore in ten stereoisomeric forms. Ordinary mucic acid and allomucic acid have the configurations

$$\begin{array}{c} COOH \\ | \\ HO-C-H \\ | \\ HO-C-H \\ | \\ HO-C-H \\ | \\ HO-C-H \\ | \\ COOH \\ \text{Allomucic Acid.} \end{array} \qquad \begin{array}{c} COOH \\ | \\ H-C-OH \\ | \\ HO-C-H \\ | \\ HO-C-H \\ | \\ H-C-OH \\ | \\ COOH \\ \text{Mucic Acid.} \end{array}$$

(Both these are inactive.)

Mudar (*Botany*). An Indian tree, *Calotropis gigantea* (order, *Asclepiadaceæ*), whose bast fibres form good material for cordage. The down on the seeds is used for stuffing cushions.

Mud Box (*Eng.*) A cavity provided in pumps, etc., to serve as a mud trap, *i.e.* to stop mud and grit from entering the valves.

Mud Bucket (*Eng.*) The bucket of a dredger, *i.e.* the part which actually scoops up the mud.

Mud Guards (*Cycles*). Made of thin iron, steel, leather, or celluloid. They should prevent mud from reaching the running parts of the machine, as well as keep it from the rider.

Mud Hole (*Eng.*) A door or hole near the bottom of a boiler or tank by means of which mud and sediment can be removed.

Mud Hole Door (*Eng.*) An elliptical plate, fitting a seating or mud hole of the same form, in boilers, etc. It is passed through the opening, then pulled up against its seating, and held fast by a bolt fixed to an arch which spans the hole outside the boiler; the internal pressure tends still further to keep it tightly closed.

Muds (*Geol.*) Clays or other argillaceous matters rendered semifluid by admixture with water. In addition to the muds of the land, rivers, and lakes, there are extensive submarine deposits which cover the ocean floor for many thousands of square miles. Most of these are of terrigenous origin. They are usually classed as (1) shallow water muds, which have been deposited in depths less than 100 fathoms; and (2) deep sea muds, which have been left at greater depths. These include blue, red, and green muds; also volcanic mud, and the calcareous mud derived from coral reefs.

Muffle Furnace (*Met., Assaying, etc.*) A furnace resembling an oven, in which cupels (*q.v.*) or small crucibles can be placed to be heated without direct contact with the flames or fuel. The actual oven, or MUFFLE, is an arch shaped vessel of fireclay.

Muffler (*Motor Cars*). A SILENCER (*q.v.*)

Mulberry. *See* WOODS.

Mule (*Cotton Spinning*). An intermittent spinning machine very suitable for medium and fine counts, soft spun yarns, and elastic yarns. It consists of three main parts: (1) the headstock; (2) draw rollers and beams; (3) carriage, which holds from 800 to 1,500 spindles placed side by side. The rovings are finally drawn out and twisted to the required fineness to form the spun thread of commerce. The drawing and twisting are done simultaneously, but the winding of the spun threads on to the spindles is performed separately, as the carriage recedes inwards. All sources of motion for the numerous operations necessary are obtained from the headstock. Mules are specially constructed for spinning (*a*) twist or (*b*) weft in coarse, medium, or fine counts. Some are capable of spinning as high as 350 counts.

Muller (*Paint.*) A flat bottomed pestle for grinding painters' colours; now seldom used.

Mullet (*Her.*) A charge formed like a star. It has generally five points, and is sometimes represented pierced or voided. The rays are always straight, thus differing from estoile, which has wavy

rays. If of more than five points, the number must be given; this is then generally called a star. When used as a mark of cadency it denotes the third son.

Mullion (*Architect.*) A vertical bar separating the lights in a Gothic window or screen. It is also known as a Monial or Munnion.

—— (*Join., etc.*) The vertical member, of larger section than a bar, that divides a window into lights.

Multicellular Voltmeter (*Elect.*) *See* VOLTMETERS.

Multifoil (*Architect.*) A cusped opening in Gothic tracery formed with a large number of foils, or spaces between cusps. *See* FOIL, CUSP, CINQUEFOIL, *and* QUATREFOIL.

Multiphase (*Elect. Eng.*) *See* POLYPHASE.

Multiple Arc *or* **Circuit** (*Elect.*) A number of conductors arranged in PARALLEL (*q.v.*)

Multiple Boiler (*Eng.*) A boiler with a number of tubes, *i.e.* a tubular boiler.

Multiple Drilling Machine (*Eng.*) A machine with a number of parallel drilling spindles; used for such work as the simultaneous drilling of a number of holes along an iron girder, boiler plate, etc.

Multiple Star (*Astron.*) A star which has one or more companions physically connected with it.

Multiple Telegraphy (*Elect. Eng.*) The simultaneous transmission of two (or more) messages along a single wire. *See also* TELEGRAPHY.

Multiple Threaded Screw (*Eng.*) A screw with two or more distinct threads or helices.

Multiplex Telegraphy (*Elect. Eng.*) *See* MULTIPLE TELEGRAPHY.

Multiplying Power of a Shunt (*Elect.*) *See* SHUNT.

Mundic (*Min.*) A synonym for PYRITES (*q.v.*)

Munnion (*Architect.*) *See* MULLION.

Munt *or* **Munting** (*Carp. and Join.*) A vertical member dividing the panels between the outside styles, *e.g.* the central vertical part of an ordinary panelled door.

Muntz Metal (*Eng.*) A kind of brass (3 parts copper to 2 parts zinc) used for the tubes of surface condensers and locomotive boilers, also for sheathing wooden ships.

Mural Crown (*Her.*) The crown is represented as made of squared stone, and is embattled.

Mural Decoration. *See* PAINTING (METHODS), CUIR BOUILLI, HOUSE PAINTING, PANELLING, WALL PAPERS, WAINSCOT, TAPESTRY.

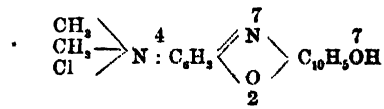
Murex (*Art*). A twisted shell portrayed as a horn: a conch. Generally an attribute of tritons, etc.

Murexide (*Chem.*) *See* URIC ACID.

Muriatic Acid (*Chem.*) A common name for hydrochloric acid (*q.v.*)

Murrey *or* **Sanguine** (*Her.*) A tincture used in ancient heraldry: a dark brown.

Muscarine (*Chem.*) 
A colourless, strongly alkaline, difficultly crystallisable syrup; very soluble in water and in alcohol; very poisonous. Forms salts with acids, and its salts give precipitates with the alkaloid reagents (*q.v.*) except iodine in potassium iodide. It occurs in putrid fish and in the poisonous fungus called fly agaric; but it is doubtful if all the poisonous action of this fungus is due to muscarine. Muscarine has been obtained artificially by the oxidation of choline (*q.v.*) by nitric acid. The same name, muscarine, has also been applied to a totally different substance—a blue dye.



Muschetors *or* **Mushetours** (*Her.*) The black tail of ermine without the three dots or spots above.

Muscle Sugar (*Chem.*) *See* INOSITE.

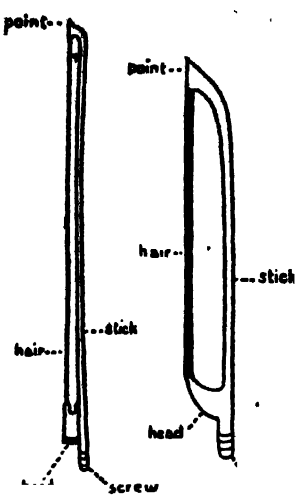
Muscovite (*Min. and Geol.*) A hydrous potassium and aluminium orthosilicate; composition rather variable, typically $2H_2O . K_2O . 3Al_2O_3 . 6SiO_2$. Monosymmetric. Usually in tabular pseudo-hexagonal crystals with a perfect basal cleavage. One of the Mica group (*q.v.*) Of wide distribution in eruptive and metamorphic rocks. It is of considerable commercial importance when in large plates, such as are obtained in the United States, Siberia, etc. It is an important constituent of most rocks that have been affected by dynamic metamorphism, this mineral being due to conversion from fragments of potash felspar. It occurs, for the same reason, in many gneisses and their related pegmatites. As an original constituent of eruptive rocks it is somewhat rare. Being, like quartz, a mineral that is decomposed by natural causes only with great difficulty, scales of Muscovite survive most of the changes that affect other minerals, and it therefore occurs, as a derivative mineral, quite commonly in most sandstones and allied rocks.

Musical Box (*Music*). A cylinder, with pins protruding, which is made to revolve by a kind of clockwork spring. In so doing the pins come into contact with certain teeth on a steel comb, tuned to the scale. The musical box is about a hundred years old, and is chiefly made in Switzerland.

Musical Instrument. A sonorous body by means of which musical sounds are produced.

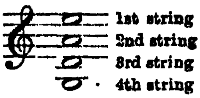
Musical Instruments. These may be divided into three classes, *viz.* (1) Stringed instruments; (2) Wind instruments; (3) Instruments of percussion. (1) STRINGED INSTRUMENTS are of three kinds: (A) Played by a bow. This class comprise the violin, viola, violoncello, and double bass. The bow consists of a stick, tapering towards the point, that has been formed by being regularly bent whilst it was subjected to a certain heat for a considerable time. Horsehair is attached to the point and head, and by means of a screw the hairs can be tightened or loosened. Resin is applied to the hairs to increase the friction on the strings of the instruments. The present bows were invented by Tourte, a Frenchman,

towards the end of the eighteenth century. The length of the bows are: violin and viola, 29 in. (about); violoncello, 28½ in. (about); double bass, 26 in. (about). (B) Played by the hand, comprising the mandoline, guitar, banjo, zither, and harp. (C) Played by percussion, comprising the pianoforte, dulcimer, and cymbals.



VIOLIN BOW. DOUBLE BASS BOW.

(A) The VIOLIN (fiddle) has four strings tuned in perfect fifths, thus:



These are called the open notes, and in fingering are

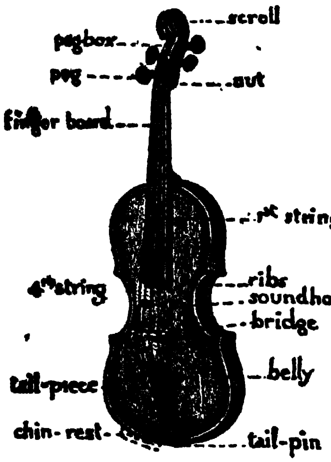


FIG. 1.—VIOLIN AND PARTS.

marked by a small o placed above the notes. It has a chromatic compass from

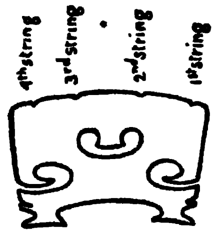

FIG. 2.—BRIDGE.

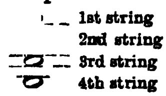
Chords of two, three, or four notes are possible if judiciously written. The illustrations (figs. 1 and 2) show the different parts of the violin and the bridge on which the strings rest. In orchestral music the violins are generally divided into two parts—firsts and seconds. The violin is the leading instrument in the orchestra, and the principal first violinist is called the leader of the orchestra. Two of the most celebrated makers of violins were Stradivarius (a pupil of Nicholas Amati) and Joseph Guarnerius, both of whom lived in the latter half of the seventeenth and the beginning of the eighteenth centuries. *See* CREMONA.

The VIOLA *or* TENOR has four strings, tuned in perfect fifths, thus:



and has a chromatic compass from

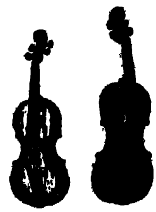


FIG. 3. VIOLIN. FIG. 4. VIOLA.
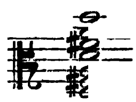
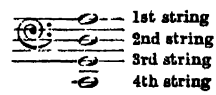
To Scale with Violoncello and Double Bass.

As on the violin, chords of two, three, or four notes are practicable. Music for this instrument, excepting the highest notes, is written in the alto stave (with the C clef on the third line). The tone of the viola is somewhat nasal, and the lower notes are especially adapted to melodies of an emotional character. The *viol da braccia* is the viol to be played supported "on the arm," and is virtually the present viola. The *viol da gamba* is the viol to be played supported "between the knees." It is now obsolete. There were two kinds—the six stringed and the seven stringed. The tone was lighter and of a more nasal character than the present violoncello. The *viol d'amore* is now nearly obsolete. It is about the size of the present viola, and has seven gut strings and seven sympathetic (resonance) strings, generally tuned as follows:



The VIOLONCELLO (CELLO) has four strings tuned in perfect fifths, thus:

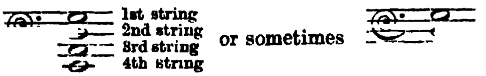


being an octave lower than the viola. It has a chromatic compass from

or even higher. Music for this instrument is written on the bass stave, excepting the higher notes, which are written on the tenor stave (with the C clef on the fourth line). Occasionally the treble stave is used, and unfortunately when this stave is used some composers have written the notes an octave higher than they are to be played, whilst others have written the actual notes. Modern composers use the treble stave only for the highest notes, and write the actual sounds. Chords of two, three, or even four notes can be played, provided they are judiciously written.

The DOUBLE BASS is of two kinds: the three stringed, tuned thus:

and the four stringed, tuned thus:



The lowest string is even tuned down to C♯ or C♮ at times. Double basses in military bands often tune to

in order to facilitate playing in flat keys, and in fact the exigency of the case regulates the tuning of this instrument. In all cases the compass extends to

with all the intermediate semitones from the lowest note according to the tuning. Music for the double bass is written on the bass stave, and the notes sounded are an octave lower than those written. Double notes are seldom written for this instrument, but passages of extreme rapidity can be performed with great effect. The actual compass of the different strings therefore is:

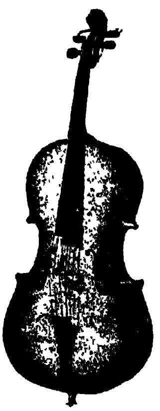


FIG. 5. VIOLONCELLO.

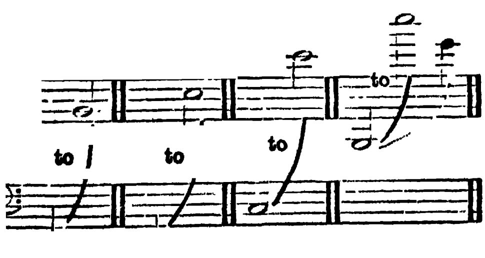
FIG. 6. THREE STRINGED DOUBLE BASS.

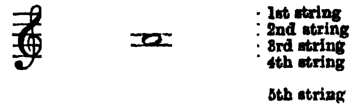
To Scale with Violin and Viola.



Double Bass. Violoncello. Viola. Violin.
(Sounding 8ve lower.)

As remarked above, the double bass lowest note varies. The note given as a crotchet is the ordinary orchestral upward compass of the second violin. *The illustrations of the violin, viola, cello, and double bass (figs. 3, 4, 5, 6) are to scale.*

(B) MANDOLINES are of two kinds: the Milanese and the Neapolitan, the latter being the more popular. The Milanese mandoline has five sets of double strings (that is, two strings tuned in unison to each note), thus:

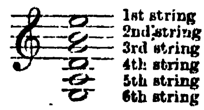


The Neapolitan mandoline has four sets of double strings, tuned to the same notes as the violin (*q.v.*), and has a chromatic compass from

NEAPOLITAN MANDOLINE.

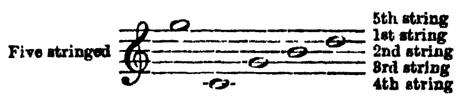
This instrument is played by plucking the strings with a "plectrum," generally made of tortoiseshell. In Sir George Grove's *Dictionary of Music and Musicians* there is printed a composition for this instrument by Beethoven, and Mozart uses it in his *Don Giovanni*. Chords of two, three, or four notes can be played on this instrument.

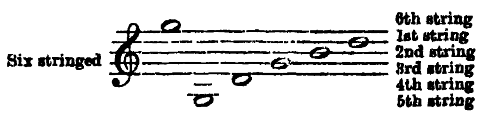
The GUITAR has six strings, tuned thus:

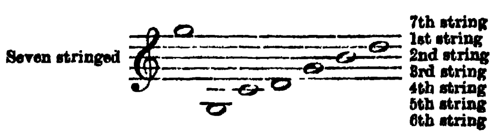


the notes sounding an octave lower than written. The tone of the guitar is of very sweet quality. It is played with the fingers, and from the way chords and arpeggios can be effectively performed it is specially suited for voice accompaniment. This instrument has a flat back.

The BANJO has five, six, or seven strings, tuned respectively as follows:

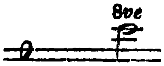




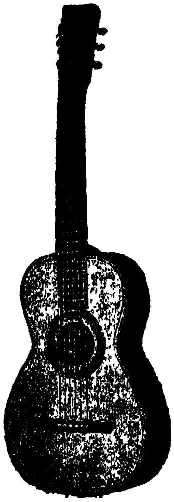


In America the tuning is a minor third lower. The

five stringed is by far the most popular. Its compass is from



including all the semitones, sounding an octave lower than the notes written. It is played either by plucking the strings like a guitar, or by striking them with the back of the nails. The highest string (fifth, sixth, or seventh) is called the melody string, and is sometimes played by striking it with a "pick" made of ivory instead of the back of the thumbnail. Chords can easily be played on this instrument.



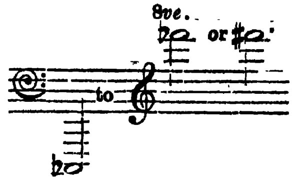
GUITAR.

FIVE STRINGED BANJO.

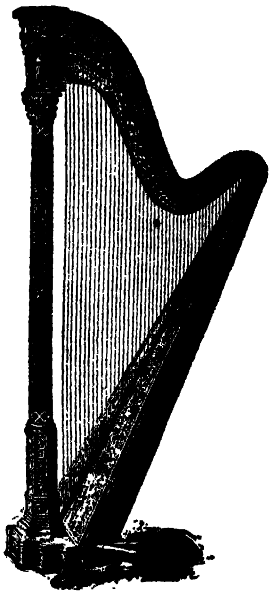
ZITHER.

The ZITHER consists of a sounding box strung with gut, silver wire, and copper strings. Five of these are on a finger board tuned like the viola, excepting that the first and second strings are tuned in unison to A. The remaining strings are called accompaniment strings, and vary in number. It is played with the fingers of the right hand and with both thumbs; the right hand thumb wears a silver ring, with which the five melody strings are struck.

The HARP is by far the most important of stringed instruments played by the hand. It has a compass from



The harp is tuned in the key of C♭, and has seven pedals, which raise their respective strings—C♭, D♭, E♭, F♭, G♭, A♭, B♭—either a tone or a semitone, at the will of the performer. For this reason it is called the "double action" harp. This double action was the invention of M. Erard, and allows music to be performed in any key. Chromatic passages, unless in very slow time, are impossible. Chords of two, three, or four notes can easily be played, especially if not extending over an octave in either hand, both of which are used to pluck the strings.



ERARD HARP.

(C) The PIANOFORTE was introduced into England at the beginning of the second half of the eighteenth century by Zumpe. Its immediate predecessor was the HARPSICHORD, the strings of which were plucked by a "quill." This quill was set in motion by a wooden upright fixed to the key, called a "jack." The harpsichord was an improved SPINET or VIRGINAL. But the oldest of this family of keyed stringed instruments was the CLAVICHORD, which dates from the early part of the sixteenth century, and which was the favourite instrument played by J. S. Bach. The

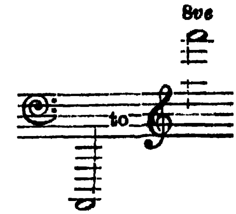
pianoforte has gone through many changes in shape since its introduction. First it was oblong; then square; then came a "grand," which was of the shape of the harpsichord; then the upright, invented by John Isaac Hawkins in 1800, in which the strings extended above and below the keys; then came the "cabinet," followed by the "cottage" piano, bringing us to the two at present in use, the "upright" and "grand." Space will not allow of going into the many inventions of such famous makers as Messrs. Backers, Stodart, Sebastian Erard, Bluthner, Pleyel, Collard, Hopkinson, Brinsmead, Steinway, Bechstein, and John Broadwood & Sons. The last named firm have been the most intimately associated with the development of this instrument in England since 1732. Fig. 1, is a reproduction of the action of the clavichord; fig. 2, the action of Zumpe's pianoforte, made in 1766; figs. 3 and 4, the present (1904) action of one of Messrs. Broadwood's upright and grand pianofortes. The modern pianoforte has a chromatic compass from



The lowest eight notes (about) have one string only to each note; the next two octaves (about) have two strings, tuned in unison to each note; and the remainder of the notes have three strings each, tuned in unison; for this reason it is known as the "trichord" pianoforte. The strings are of steel wire, strung at very great tension (the total strain is from sixteen to thirty-two tons in a modern pianoforte), and are struck by hammers covered with felt worked from the keys. To each string, or set of strings, a damper of felt is added, which rests, when the key is released, against the strings, thus "damping" them and

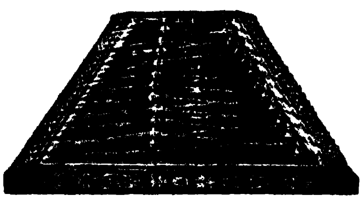
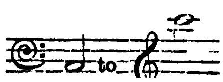
preventing them from vibrating. When the dampers are above the point at which the hammers strike the strings, it is known as the over-damper action; when below the point at which the hammer strikes the strings, as the under-damper action: this last is somewhat more quick in its action. Pianofortes have two or three pedals; if only two, that on the right is the sustaining pedal (popularly but erroneously called the loud pedal), which when depressed by the foot causes the dampers to remain away from the strings, allowing the vibration of the strings to continue. Its use is denoted by the abbreviation "Ped.," and its release is denoted by an asterisk. [It may here be pointed out that although the passage to be played is marked pianissimo, "Ped." would still stand for the right (sustaining) pedal, and not the left.] The pedal on the left is indicated by the words *una corda*, which mean "one string." This is brought about by the pedal shifting the action so that the hammers strike only one string instead of the three, the result being a diminution and remarkable difference of tone in the sound power. In modern trichord pianofortes, however, this pedal only shifts the action so that the hammers strike two of the strings instead of the three. In some instruments, instead of the former action, a strip of felt is dropped between the hammers and the strings when the left pedal is depressed, giving a muffled tone to the sound; this is called a *celeste pedal*. A third action of this pedal shifts the hammers nearer the strings; but the same result can as easily be attained by playing with less force. The release of the left pedal is indicated by the words *tre corde*, "three strings." On those instruments which have three pedals, the middle one holds the dampers exactly as they are when put into use, *i.e.* allowing the vibration of those strings which have the dampers off to continue, whilst damping the remainder of the strings so long as the pedal is kept depressed.



DULCIMER.

The DULCIMER: A small instrument, in no part more than 3 ft., with a wooden frame, and strung with from two to five wires in unison to each note. Its compass is from about

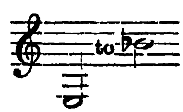


It is played by laying the instrument on a table or trestle and striking the wires with two hammers covered with leather, one in each hand. This instrument, being without dampers to stop the vibration of the wires, gives, especially in *forte* passages, a very confused combination of sounds.

The CIMBALO or CZYMBALO: A species of the dulcimer family, so called from its bell-like quality of tone. It has a compass of thirty-five notes. The lowest note has one string, the next fifteen notes have three strings each tuned in unison, and the remaining nineteen notes have four strings each tuned in unison. It is used a good deal by the Hungarian bands.

WIND INSTRUMENTS are of four kinds: (1) Those played by means of a reed mouthpiece, comprising the clarionets and saxophones (which have a single vibrating reed), and the oboe, oboe d'amore, cor Anglais or corno Inglese, the bassoon, the contra-bassoon (double bassoon), and bagpipes, each having a double vibrating reed. (2) Those played by means of a lateral mouthpiece, comprising the piccolo and flute. (3) Those played by means of a cup shaped mouthpiece, comprising the French horn, trumpet, trombone, cornet, flugel horn, tenor horn or saxhorn, baritone, euphonium, and bombardon (the last six comprise the "family" of SAXHORNS). (4) Those played by means of a keyboard, comprising the organ, harmonium, and concertina. The classification "wood" and "brass" has been avoided, firstly because instruments such as the flute, etc., though often made of wood, are also made of metal or ebonite; and, secondly, because the saxophone, although a brass instrument, is played by means of a reed, and so cannot strictly be classed in the same list as the trumpet, etc. In the first three classes of wind instruments the bore of some is cylindrical, that of others conical. With regard to the material used in instruments such as the flute, etc., it may be said that whilst it is more difficult to manufacture a "true" wooden instrument than one in metal, because of the liability of the wood to alter by warping, in performance the wooden one is more likely to remain true in pitch than the metal, owing to the effect produced by the heat of the breath. The variation is especially noticeable after a fairly long rest, unless the performer takes the precaution to keep the instrument warm. The SINGLE REED is made from a strip of cane, which beats or vibrates against the mouthpiece of the instrument. The DOUBLE REED consists of two strips of cane fastened together.

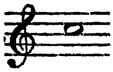
(1) The CLARIONET or CLARINET: An instrument of cylindrical bore ending in a bell, played by means of a single flat reed held by a double band to the mouthpiece. This instrument has a greater length in comparison to the size of the bore than any other of the conveniently termed "Wood wind" family (flute, oboe, clarionet, and bassoon), and this gives it a register of nineteen chromatic notes from



which is called "Chalumeau"; this is of a different quality from the other registers. By using the same fingering and opening the hole at the top of the instrument, a new series of sounds, a perfect twelfth higher, is obtained. In orchestral music three clarionets are in use, *viz.* in C, in B♭, and in A, but that in C is seldom used now, owing to its somewhat hard and unsympathetic tone. In military bands the clarionet in E♭ and others described below are in use. With the exception of the clarionet in C, all these are transposing instruments, *i.e.* the notes played are different from those written.

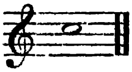
CLARIONET

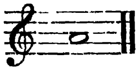
For instance, in a non-transposing instrument, like the clarionet in C, the note

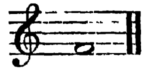


would sound exactly as written; whilst in transposing instruments, like the clarionet in A or the horn in F (*see* below), it would give the note by which the instrument is known, *e.g.*

Note written.	Note sounded by Clarionet in A.	Note sounded by Horn in F.



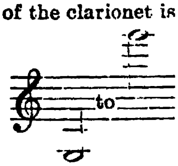




This necessitates the music being written in a key that allows for this transposition, and also prefixing a direction stating which instrument is to be used, as clarionet in A, or clarionet in E♭, etc. The transpositions of the clarionets are:

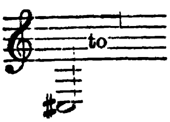
B♭	1 tone lower.
A	$1\frac{1}{2}$ tones lower.
E♭	$1\frac{1}{2}$ tones higher.

The full compass of the clarionet is from



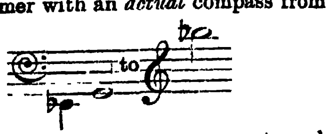
with all the semitones, the actual sound compass being as follows: Clarionet in C as given above; clarionet in B♭

Clarionet in A

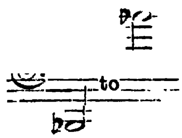


Clarionet in E♭

The instrument has from thirteen to fifteen keys. The choice of instruments obviates the need of writing in keys with many sharps or flats. Besides the foregoing instruments, there are tenor clarionets in E♭ and F, the former with an *actual* compass from



and the latter an *actual* compass one tone higher than the previous. Some makers add four lower keys to these tenor clarionets, carrying the compass down four more semitones to the note given as a crotchet in the compass of the tenor E♭. Both are transposing instruments, the E♭ a major sixth lower, and the F a perfect fifth lower than the written notes. This family is completed by the bass clarionet in B♭, which has a three-octave *actual* compass from



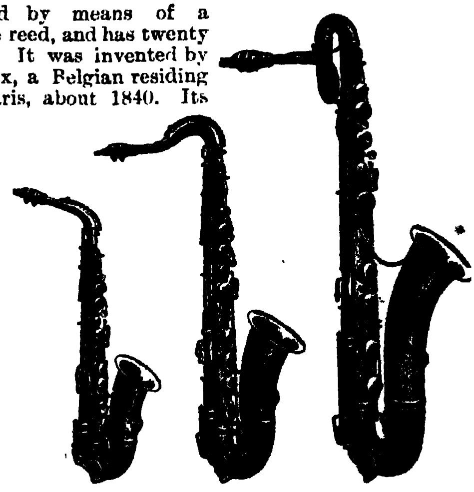
Music for this instrument is written either in the bass clef with the actual notes, or in the treble clef in the key of C; in the latter case it is a transposing instrument, sounding a major ninth lower than the notes written.

TENOR AND BASS CLARIONETS.

The BASSET HORN (*Corni di Bassetto*) is a similar instrument to the tenor clarionet in F, with the addition of four lower keys, and has a written compass from

It is a transposing instrument, sounding a perfect fifth lower, and possesses a fuller and finer tone than the clarionet.

The SAXOPHONE consists of a conical brass tube played by means of a single reed, and has twenty keys. It was invented by M. Sax, a Belgian residing in Paris, about 1840. Its



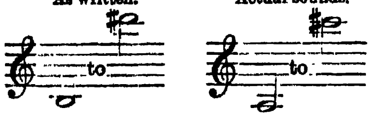
SAXOPHONES.

SOPRANO. ALTO. TENOR. BARITONE.

tone reproduces something of the 'cello quality, and gives sustaining power to the "full brass." It is used chiefly in military bands. We give illustrations of the four most frequently used saxophones, showing their relative sizes; but in addition there are the sopranino saxophone in E♭, an octave higher than the alto in E♭ (the alto is the favourite with saxophone soloists), and a bass saxophone in B♭, an octave lower than the tenor in B♭; they are, however, seldom used. The following table gives the compass of the instruments:

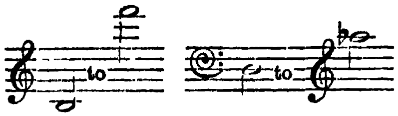
Soprano in B♭

As written. Actual sounds.



A tone lower.

Alto in E♭

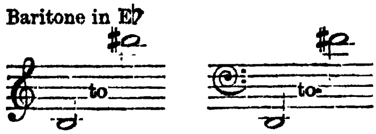


A major 6th lower.

Tenor in B♭

A major 9th lower.

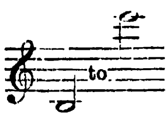
Baritone in E♭



A major 13th lower.

It will thus be seen that all are transposing instruments (*see* CLARIONET) and music is always written in the treble clef.

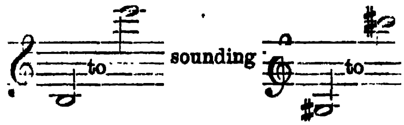
The OBOE: An instrument with a conical bore exceedingly small at the top. It has a delicate, refined, and plaintive tone, and is played by means of a double reed. It is an octave instrument, higher notes being obtained by octave keys. Its compass is from



or even a third higher with all the semitones. It has from fifteen to seventeen keys, and is a non-transposing instrument. The oboe is essentially a melodic instrument, and, owing to the difficulty in emitting the breath whilst playing, it is very necessary to give the player frequent rests. The best keys are those with not more than three sharps or flats in the signature. In the orchestra the performers tune their several instruments to the A given out by the oboe. Oboes are also made in B♭ and D♭, the former transposing a tone down and the latter a semitone up. The OBOE D'AMORE is a very similar instrument to the oboe. Its

OBOE.

quality of tone is more plaintive than the oboe, but in mechanism it is like that instrument. It is a transposing instrument (*see* CLARIONET), being in A, a minor third lower than the notes written. Its compass is from

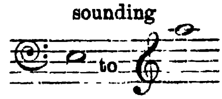


with all the semitones. Some very fine parts were written for this instrument by J. S. Bach, and latterly the instrument has been reconstructed and used at the performances of the Bach Choir in London.

COR

COR ANGLAIS (CORNO INGLESE) is to the oboe what the basset horn is to the clarionet (*q.v.*) It is a transposing instrument, being a fifth lower in the key of F. Its actual compass is from

sounding



The BASSOON (FAGOTTO) has, like the oboe (of which it is the bass), a double reed attached to a metal tube, called the crook, which is about 12 in. long. The crook is fitted in the instrument at (*a*) in the accompanying illustration, which shows the back and front of the bassoon. This instrument has a conical bore, and its internal length, with the crook, is a little over 8 ft. It has from seventeen to twenty-two keys. The instrument is supported by a strap placed around the performer's neck. It has a chromatic compass from

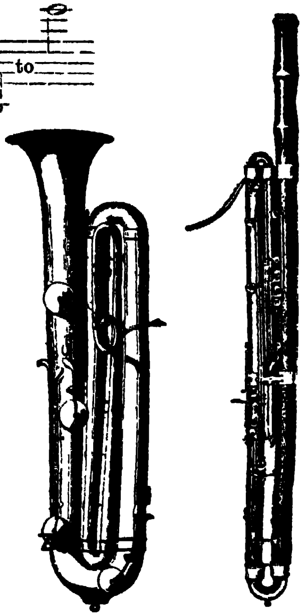
(three octaves), and is a non-transposing instrument; soloists even play good toned notes up to the F above. Music for the bassoon is written in the F (bass) and C clefs, the latter on the fourth line (tenor clef), and almost any kind of passage can be played effectively.

The CONTRA BASSOON (CONTRA FAGOTTO) or DOUBLE BASSOON is an octave lower in pitch than the bassoon, and it is curved four times for ease of handling. It is a little over 12 ft. in length internally, including the crook, and sounds an octave lower than the notes written, like the double bass. The fingering

BASSOON.

is similar to the bassoon and the compass is from

with all the semitones sounding an octave below. A new double bassoon has been introduced. It is made of brass, with a double reed resembling that of the bassoon, but somewhat larger, and is claimed to be much simpler in fingering and easier of performance. The tone is soft in quality, although of great power, and its compass is from

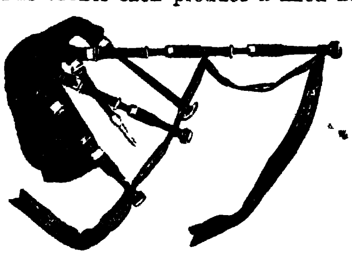


BRASS DOUBLE BASSOON. CONTRA BASSOON.

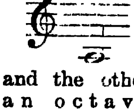
sounding an octave lower. Illustrations of both instruments are given.

THE HIGHLAND BAGPIPE consists of a leathern windbag which is filled by the performer through a valved tube, and three long tubes called drones and a smaller tube to which is fitted the chaunter. These four tubes are all inserted in the windbag, and the drones are thrown over the shoulder, while the chaunter tube is held in the performer's hand. The chaunter is fitted with a double reed, like the bassoon, whilst the three drones have single reeds of cane that in principle work very similarly to the organ reed. The chaunter is conical in shape, with seven finger holes in front and one behind, having a compass of nine notes from

The drones each produce a fixed note according to the tuning used, which is either two in unison to



HIGHLAND BAGPIPE.

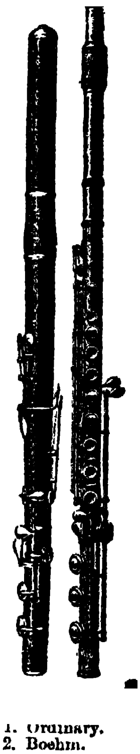


and the other an octave lower; or to G, D, G, or D, A, D. The ornamental notes produced are called "warblers." The IRISH BAGPIPE has a windbag inflated by means of a bellows worked by the arm. Its tone is softer, and it has a compass from

The drones are mounted all in one stock. This bagpipe is also called the UNION PIPES. Besides the foregoing there are the Northumbrian and other bagpipes.

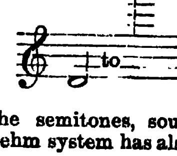
(2) The FLUTE is a tube made of cocoa-wood, ebonite, or silver, with either a conical or a cylindrical bore, and is played through a hole in the side about an inch from the head of the instrument. For this reason it was called *flauto traverso*, to distinguish it from the *flute à bec* or direct flute, now represented by the flageolet, an instrument which is fast disappearing. In *conical* flutes the head (top joint) has a cylindrical bore, which gradually decreases in size towards the end or foot joint. In *cylindrical* flutes the bore of the foot and body are cylindrical, but it tapers towards the top in the head joint. The flute has from about eight to twelve keys and a chromatic compass from

(or even down to B♭), but the two top notes are both difficult and harsh. Many systems of fingering are in use, the principal being that of Böhm (or Boehm), which allows of the more difficult keys being used with greater ease. Boehm also, in place of the old plan of boring the holes to suit the fingers, substituted (about 1834) a system of mathematically correct boring with special mechanism to suit this arrangement. The orchestral flute is a non-transposing instrument. There is also a flute in E♭ (often spoken of as the third flute in F, but tuned in E♭), which transposes a minor third higher (*see* CLARIONET); also a flute in B♭ (which should be more appropriately called in A), transposing a minor sixth higher; and a flute in E♭ (more appropriately in D♭), transposing a semitone higher. The flute is able to play very rapid passages, and is assigned the highest part in orchestral music.



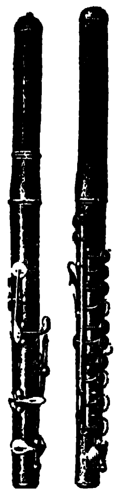
1. Ordinary. 2. Boehm.

The PICCOLO, or OCTAVE FLUTE, as its name implies, transposes an octave higher than the notes written. Its compass is from



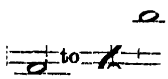
including all the semitones, sounding an octave higher. The Boehm system has also been applied to

this instrument. There are also piccolos in E♭ and F, transposing respectively a minor second and minor third higher, and should more appropriately be termed in D♭ and E♭.



Piccolos.
1. Ordinary.
2. Boehm.

(3) The FRENCH HORN: A brass instrument of peculiar softness of quality, played by means of a circular mouthpiece. In shape it is spiral with a bell-shaped ending, into which the hand can be inserted to obtain certain sounds called closed notes. This instrument is played by means of different *embouchures* (different positions of the lips), which produce the series of natural harmonics. By means of "crooks" — smaller interchangeable tubing—it is possible to get the horn in any key. The compass of the horn in C is from



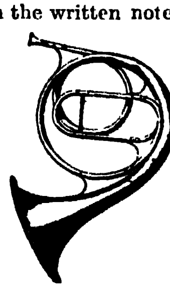
sounding an octave lower than written. All horns are transposing instruments. *See* CLARIONET. The following is a list, with the transpositions:

Horn in B♭ alt.	A major 2nd lower	
A	A minor 3rd ,,	
A♭	A major 3rd	
G	A perfect 4th	
F	A perfect 5th	These crooks are the most effective for both hand and valve horns.
E	A minor 6th	
E♭	A major 6th	
D	A minor 7th	
C	An octave ,,	
B basso	A minor 9th ,,	
	A major 9th ,,	

Horns can also be "crooked" in G♭ and D♭, thus giving a complete set. It may here be noted that music for the horn is written in the treble clef, except for the lowest notes, which are *sometimes* written in the bass clef. When this latter clef is used, the notes are written an octave lower than they would be in the treble clef. *e.g.*

 would be written  not 

From this it will be seen that the actual sounds of all horns above C are lower than the written notes when the treble clef is used, and higher when the bass clef is used; whilst the horns in C, B basso, and B♭ basso are higher when the treble clef is used, and lower when the bass clef is used, excepting the horn in C, which is correct when the bass clef is used. Music for the horn is always written in the key of C, prefixing which horn is to be used, *e.g.* Horn in D, Horn in F, etc.; and as most



French Horn.

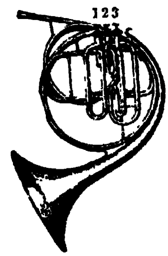
orchestras have either two or four horns, these are generally in different keys, so as to enable a greater number of open notes to be used. Other notes than the harmonics can be obtained by inserting the hand into the "bell"; these are called "closed" notes, and have a great difference in tone, being less brilliant. The following shows the notes obtainable on the hand horn in F, the closed notes being written as crotchets, and those obtained by inserting the hand farther into the bell, and called double closed notes, are written as quavers:

Written notes.

(*a*) This note is better when taken as a double stopped note from the tone above (c).

* These four notes, says Berlioz in his *Treatise on Orchestration*, are bad, dull notes.

The loss of a complete chromatic scale on this most interesting instrument led to the introduction of valves or ventils. This instrument is known as the VALVE HORN. By pressing the finger on a valve, it opens and thus lengthens the tube. It has a distinct advantage over the hand horn; for firstly it produces the same tone and notes as the latter instrument if the valves are left untouched (and composers, whenever they wish a note to be played as on the hand horn, have only to mark the note or notes *bouchée* or by some other sign); and, secondly, it has a chromatic scale of even quality. To the valve horn are attached three valves—ventils or pistons (*see* illustration), the first finger lowering the note a tone, the second finger lowering it a semitone, and the third finger lowering it a tone and a half. These can be used in combination, *e.g.* the first and third will lower a note two and a half tones. The following shows the notes obtainable with the fingering of the valve horn in E♭. The open notes are left



Valve Horn.

unfingered, and where more than one finger is put, these are to be used in combination.

(*b*) These notes, if marked *bouchée*, can be played as stopped notes, and those marked (*c*) as double stopped notes, as on the hand horn.

The actual sounds are a major sixth lower than those written. The French horn is one of the most difficult of wind instruments, and it is advisable in writing orchestral music to limit the compass of the first horn by not going below

, and by not going above 

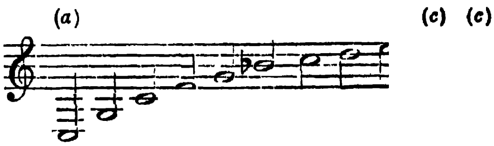
for the second horn. It is only necessary to add that the horns in D and C exceed the compass given above by five semitones, going to

whilst those in B♭, A, A♭, and G do not go above 

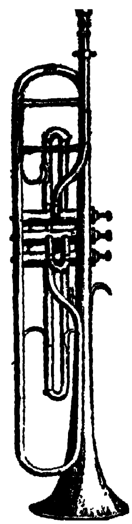
and that in B♭ basso only has a compass from

The **Tenor Cor** may be termed "the amateur's French horn." It has a mouthpiece of the saxhorn type, and is conical from the mouthpiece. It is very much easier to play than the French horn. In shape it is similar to the French horn, but it is held in the reverse manner, the right hand fingers being on the pistons and the left hand holding the bell. Its compass is the same as the French horn.

Trumpet (Tromba): The trumpet is a cylindrical brass instrument curved and ending in a "bell." It is played by means of a cup-shaped mouthpiece, shallower than that used in the cornet, and has a brilliant, penetrating tone. Like the horn, the sounds produced by means of different positions of the lips, called *embouchures*, are the natural harmonics. To increase these harmonics "crooks" (*see* Horn) are added, thereby giving the series from different foundation notes. The crooks in use are the F, E, E♭, D, C, and B♭. With the exception of the C crook all these are transposing instruments (*see* Clarionet), those in F, E, E♭, and D sounding higher, and those in B♭ and A a tone and a tone and a half lower respectively than the notes written. The notes obtainable on the D and D♭ trumpets are:



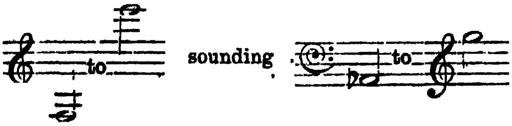
the actual sounds being a tone and a semitone higher respectively. The note marked (*a*) cannot be obtained on the C, B♭, and A crooks, nor those marked (*c*) on the F, E, and E♭ crooks, except by very accomplished players. The F♯ is obtained by somewhat overblowing the naturally too sharp F, which therefore is omitted. This limited series of notes accounts for the use the great masters made of this instrument, *viz.* chiefly for rhythmical effects. Bach and Handel wrote their trumpet parts, using notes up to



Valve Trumpet.

or even higher; but with the present mouthpiece these notes are extremely difficult of production. To meet this difficulty and avoid the deplorable custom of substituting cornets for trumpets, Messrs. Mahillon & Co., of London, have constructed a new instrument with a special mouthpiece, which they have called a "Sopranino Trumpet in Upper D," and which enables these highest notes to be produced with comparative ease. Trumpets are also constructed in upper B♭, with the same fingering as the cornet in B♭, and are extensively used in Paris, Brussels, Berlin, etc. Unlike the horn, the trumpet bell will not allow of the hand being inserted for closed notes. To increase the usefulness of the trumpet, valves have been added, as in the case of the horn, and the natural trumpet has been completely superseded by the **Valve Trumpet**, which becomes a melodic as well as a rhythmical instrument, having a complete chromatic scale throughout the compass shown above for the natural trumpet. These valves are explained above in the horn. Modern composers write for the valve trumpet, and use chiefly the most effective crooks, *viz.* F, E, and E♭, the first of these being most used. Besides this instrument, there is also a slide trumpet, but its intonation is not so certain. The effect of the slide is explained under **Trombone**. Music for the trumpet is written in the key of C and in the treble clef, directions being prefixed as to which crooks are to be used, *e.g.* Trumpet in F. Wagner used trumpets

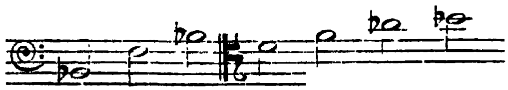
in E♭ basso and in D and C basso. This trumpet in E♭ basso has a chromatic compass from



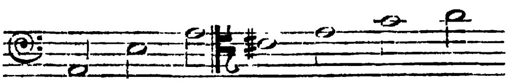
and by extra crooking those in D and C basso are obtained.

The **Trombone** consists of a twice bent tube with a bell shaped ending, made in the middle in such a manner that the slide (outer section) can move on the inner section. Like the French horn, the notes obtainable are the natural harmonics, and by extending the slide (which is held in the player's right hand) to the different positions, this set of harmonics can be repeated in different degrees, each a semitone below the other. Below are given the harmonics produced in the first and second positions of the tenor trombone; the remaining five positions can easily be found by transposing the series of harmonics a semitone lower for each position.

Harmonics produced in first (or "home") position.

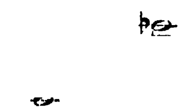


Harmonics produced in second position.

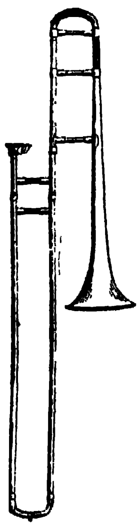


In the first four positions a note an octave lower than the first given above can be produced. These notes are called pedal notes. There are three trombones: the alto in E♭, with a chromatic compass from

the tenor in B♭, with a chromatic compass from



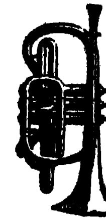
and the bass in G or in F, with a chromatic compass from



Slide Trombone.

Besides the slide trombones, there are the valve trombones, which have the same compass respectively, and are easier to learn. Trombones are largely used in the orchestra on account of their beautiful effect in both *piano* and *forte* passages, the tone being noble and rich; splendid examples can be found in Mendelssohn's scores. Trombones are non-transposing instruments, and the music is written in the alto, tenor, and bass clefs respectively.

Saxhorns:—The Cornet: A brass instrument with a cup shaped mouthpiece; it has three valves, working as in the valve French horn (*q.v.*) The tone is less brilliant than that of the trumpet, and its execution less difficult. The cornet may be called the treble of the saxhorn family. When trumpets cannot be obtained the cornet is used as a substitute. Cornets in B♭ and A are generally used, but by using crooks other keys are obtainable. With the exception of that in C, cornets are transposing instruments (*see* Clarionet), sounding lower than the written notes. It has a chromatic compass from

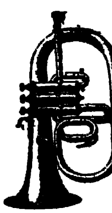


Cornet.

(written notes)

There is also a soprano cornet in E♭, transposing a minor third higher. Music for the cornet is always written in the treble clef. For fingering *see* Flugel Horn.

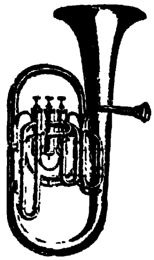
The Flugel Horn is treated the same as the cornet; but it has a much larger bore, being more like the bugle. Its compass is the same as the cornet. It is made in B♭, having three valves. The following is the fingering on the flugel horn, and, the compass being the same on the two following instruments, the fingering on those (as well as the cornet) is identical. The notes in semibreves are open notes, and the last three notes should be sparingly used:



Flugel Horn.

The flugel horn is a transposing instrument (*see* Clarionet), the actual notes being a tone below.

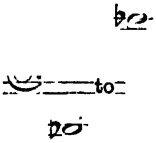
The SAXHORN or TENOR HORN in E♭ is the next of the saxhorn family. Its compass is a perfect fifth below that of the flugel horn. The saxhorn is used in combination with or as a substitute for the French horn, but the latter instrument is decidedly finer in tone. Besides the E♭ there is an F crook. Both are transposing instruments (*see* CLARIONET), the actual notes being a major sixth and perfect fifth below respectively. The fingering is given above. *See* FLUGEL HORN.

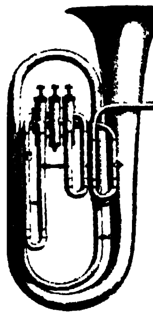


SAXHORN OR TENOR HORN IN E♭.

The BARITONE in B♭ is the next of the saxhorn family. Its compass is an octave below the flugel horn. It is a transposing instrument (*see* CLARIONET), the actual notes being a major ninth below. The fingering is given above. *See* FLUGEL HORN.

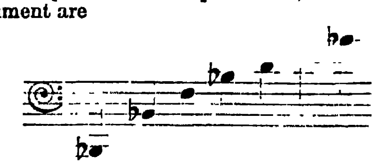
The EUPHONIUM is a brass instrument, usually with four valves, belonging to the saxhorn family. It is the bass soloist of the military band, having taken the place of the ophicleide, which in its turn took the place of the serpent. It is a non-transposing instrument, and has a chromatic compass of three octaves, from





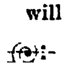
BARITONE.

Besides the shape given in the illustration, there is a circular euphonium. Music is written in the bass clef. The valves, as explained above in valve horn, lower the pitch of the open notes, which on this instrument are

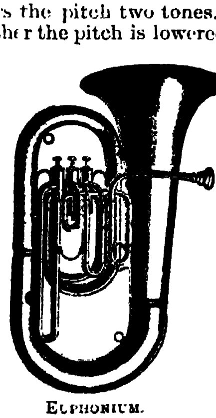


as follows: First, a tone; second, a semitone; third, one and a half tones; fourth, two and a half tones. (Abroad the third valve lowers the pitch two tones.) By using the four valves together the pitch is lowered five and a half tones. It will thus be seen that by using the four valves this note

will give



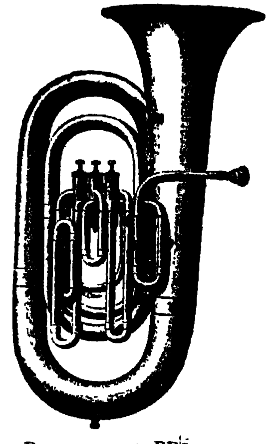
the second note in the chromatic compass of the euphonium.



EUPHONIUM.

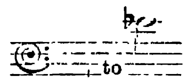
The TENOR TUBEN and the BASS TUBEN are brass instruments, partly cylindrical and having a longer and narrower bore than the euphonium: the tenor is in B♭ and the bass in F, and each has four valves. The compass of the tuben is from

the tenor sounding a major second lower, and the bass a perfect fifth lower than the written notes. The tuben may be said to have been invented by Wagner, who used them in his works; for instance, in the *Trauer-marsch* in the *Götterdämmerung*.

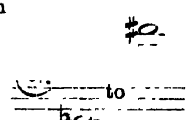


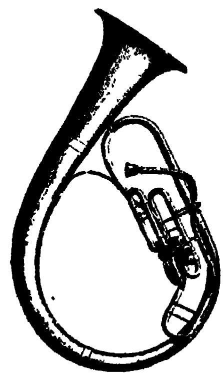
BOMBARDON IN BB♭.

BOMBARDON, the lowest of the saxhorns, is of two shapes: one like the euphonium, but larger; the other circular, encircling the body and resting on the shoulder of the performer. They have mostly three valves (occasionally one with four valves is found), and are of two pitches, the E♭ and the BB♭. These, with the stringed double basses, are the lowest instruments in the military band. The chromatic compass of the E♭ bombardon is from



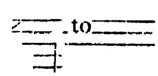
those with four valves going down to E♭ three octaves, and of the BB♭ bombardon from





NEW MODEL CIRCULAR BOMBARDON.

The music is written in the bass clef, bombardons being non-transposing instruments. The BASS TUBA is a species of bombardon having a noble tone. It is a non-transposing instrument, and has the largest compass of orchestral instruments, *viz.* from



or even descending to a fourth below. Music for the bass tuba is written in the bass clef. *The illustrations of the cornet, flugel horn, tenor horn in E♭, baritone in B♭, euphonium, and bombardon show the relative sizes of the saxhorns.*

(4) The **Organ**: This is by far the most important of wind instruments played by means of a keyboard, and only a very brief description of the various parts of the construction can be given. The accompanying illustration (fig. 1) shows the several parts leading from key to pipe. At the back of the key (1) is inserted an upright rod called a sticker (2), running up through one end of a lever or backfall (3); the other end of this lever falls when the key is depressed, pulling down the tracker (4), which is fixed to one arm (5) of the roller. Rollers are used to reach the pallets, which are generally out of the vertical line of the action from the keys. They consist of metal rods turning on pins and having a short arm at each end (fig. 2). The tracker from the backfall is fitted to one arm, and to the other arm is fitted the pull down wire (6), which is moved when the tracker gives the roller the necessary movement. The pull down wire opens the pallet (7), allowing the wind to pass from the wind chest (8) to the grooves (9) in the sound board, over which the pipes stand. The pallet is supplied with a spring (10) to close it immediately the key is released, and so restore the action to its original position. Besides rollers, *squares* of wood or brass are used for carrying the action from key to pallet. In addition to the foregoing action, which is called the **Tracker Action**, there is the **Pneumatic Lever Action**, which sometimes is applied to the whole of the keys, and at other times only to the lowest octave. This consists of a small bellows attached to the pull down and pallet, which is filled by compressed air when the key is played, thereby opening the pallet, and is emptied when the key is released, allowing the pallet to close. This action is much lighter to the touch

than the tracker. A third action is the **Tubular Pneumatic Action**, which does away with the use of trackers—tubes connecting the key and the small bellows under the pallet. The wind is admitted to this tube when the key is depressed, and carried to a small circular chamber covered by a disc of leather called a "puffer." This puffer, being lifted by the wind, operates a small pneumatic bellows connected with the sound board pallet. When the key is released the reverse action takes place, thus allowing the pallet to close. A fourth action is the **Electro-Pneumatic**. In this action, instead of the pulse of compressed air through the long tube, electricity is used. By depressing the key contact is formed, and the current passes through a small electro-magnet, which, attracting an armature, opens the valve that operates the pneumatic action. With these two last actions the **Console** (consisting of the manuals, pedals, draw stops, accessories, etc.) can be carried to a distance from the instrument proper, allowing the organist to judge better the effect produced by the organ. The accompanying illustration (fig. 3) shows the console of an electro-pneumatic organ built in 1888 by Messrs. J. W. Walker & Sons, London, the cable on the left connecting to organ. The upper part of the wind chest is called the **Sound Board** (11, fig. 1). Each set of pipes is known as a **Stop**, and is brought into action by a draw stop being drawn out. This in turn draws into position the corresponding **Slider** (12). The draw stops are placed at the right and left of the console, each bearing its name (it should also bear the pitch) on the knob. The slider, or slide, is a perforated flat strip of hard wood which covers and uncovers the holes in the upper surface of the board above the channels of the sound board, called a **Table** (13), and below the **Upper Board** (14), which supports the pipes. This upper board is also perforated with corresponding holes. By drawing the draw stop the slider is drawn into such a position that the holes in the table, slider, and upper board are over each other, thus allowing the wind to pass to the pipes when the pallets are opened. When the draw stop is in, the slider shuts off the wind between the table and upper board. Should the wind from some defect be not properly shut off from the pipe, this is known as a **Ciphering**. The pipes are placed as a rule in succession a tone apart, having the two largest pipes at the two ends of the sound board, the position being: Bass end, C, D, E, F♯, G♯, A♯, C, etc.; treble end, C♯, D♯, F, G, A, B, C♯, etc., so working towards the centre with the smallest pipes placed there. The pipes are held in position by a framework placed a few inches above the upper board, known as the **Pipe Rack** (15). The **Bellows** are the lungs of the organ, and consist of (*a*) the **Feeders**, which are operated by the blowing handle, (*b*) a **Bottom Board** perforated with holes, through which the air, compressed by the feeders, passes into (*c*) the **Reservoir**, which is kept filled by the feeders. The holes in the bottom board are covered by leather pallets, which prevent the air returning into the feeders from the reservoir. From the reservoir of the bellows the wind is taken either direct or through intermediate reservoirs to the wind chest of the sound board by wind trunks, which are ducts of wood or zinc. The reservoir is weighted so that the wind supplied to the pipes may be

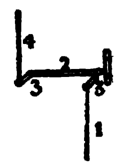

Fig. 2.

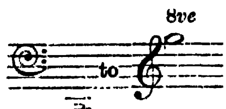
1. Tracker.
2. Roller.
3. Roller arms.
4. Pull down wire.

compressed. The pressure varies in different organs, $2\frac{1}{2}$ to 4 in. being the most usual when only one pressure is used; but many organs have the reeds and other portions of the stops on varying pressures, even up to 25 in. The **Manuals** are the sets of keyboards played by the hands, and are placed one above the other, but somewhat overlapping. *See* fig. 3. In organs with only one manual, that manual is called the **Great Organ** (*Hauptwerk*, in German; *Grande Orgue*, in French), and the pipes of the great are of large scale and full tone. If there are two manuals, the lower is the great and the upper the **Swell Organ** (*Oberwerk*, German; *Recitatif*, French). In the swell, all the pipes acted on are in a box which is fitted with Venetian shutters. These shutters are opened and closed by means of a swell pedal fixed above the pedals, thus giving a crescendo and decrescendo in the tone. These pipes are of smaller scale, and several are of the reed class. In three-manual organs the third manual is placed beneath the two former and is called the **Choir Organ** (*Positiv*, German; *Positif*, French); these pipes are of a soft character, and are intended for accompanying the choir in the softer passages. In four-manual organs we find, above the former three mentioned, the **Solo Organ**, having chiefly pipes of a solo character; whilst above this solo organ a fifth manual is sometimes placed, called the **Echo Organ**, the pipes of which are of a delicate nature and placed in a swell box. Besides these keyboards there is on all organs another keyboard played by the feet, and called the **Pedals**. *See* fig. 3. In the pedal organ are pipes forming a bass suitable to the different manual stops, and of lower tone. The pedal keyboard is either radiating, concave, radiating and concave, or concave and straight. The pedals generally consist of thirty notes, corresponding to the lowest thirty notes of the manuals, and as the foundation tone of the pedals is 16 ft., these notes are spoken of as CCC to F. The compass of the manuals varies from fifty-six notes



(CC to g^2)

to five octaves

(CC to c^3)

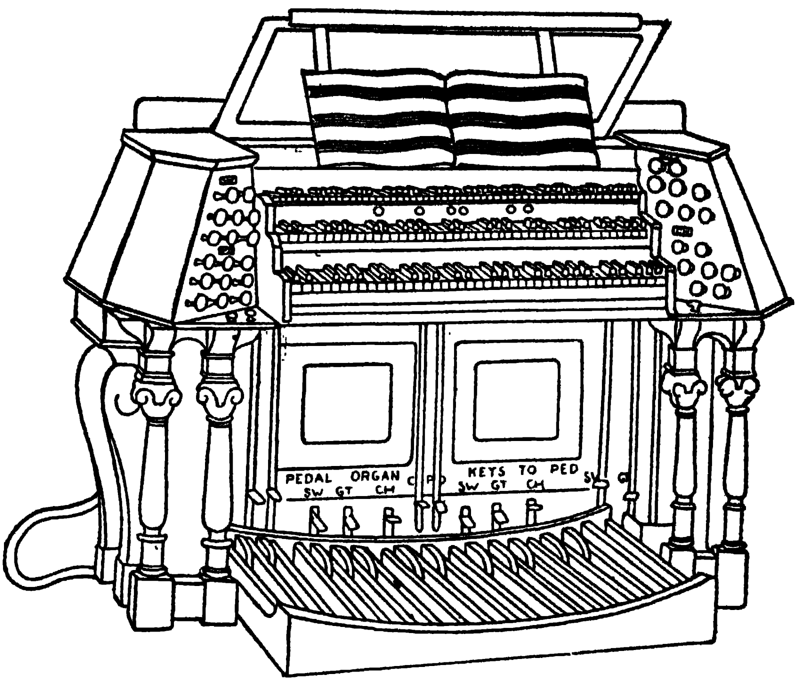


Fig. 3.—Moveable Console of an Organ.

The draw stops of each organ are generally arranged in the following groups:

Left Side of Console.	Right Side of Console.
Swell organ.	Solo organ.
Pedal organ.	Great organ.
Couplers.	Choir organ.

Speaking stops are divided into Foundation, Mutation, Compound, and Reeds. Some of the most usually found are:

Foundation Stops (Manual).

16 *ft. tone, i.e. sounding an octave lower.*

Double open diapason .	Metal; open.
Contra gamba . . .	Metal; open, slotted.
Double stopped diapason .	Wood; stopped.

[Stopped pipes are those having a plug in the top (*see* fig. 5), and being of only one-half the length of an open pipe, yet give the same sound as the open pipe.]

8 *ft. tone, i.e. sounding the same pitch as a pianoforte.*

Open diapason . .	Metal; open.
Violin diapason or Geigen principal	Metal; open, small scale, stringy.
Horn diapason . .	Metal; open, reedy.
Gamba . . .	Metal; open, slotted, reedy.
Echo gamba . .	A small scale gamba.
Keraulophon . .	Metal; a species of gamba.
Salcional (salicional)	Metal; open, small scale.
Dulciana . . .	Metal; open, very small scale.
Rohr flute . . .	Metal; stopped with a hole in the stopper.
Stopped diapason .	Wood; stopped.

Lieblich gedact	Wood; "sweet" toned and stopped.
Clarabella . .	Wood; open.
Hohl flute . .	Wood; open.

4 ft. tone, i.e. sounding an octave higher.

Principal . .	Metal; open.
Gemshorn .	Metal; open.
Harmonic flute	Metal; of 8 ft. length with a hole midway, causing sound to be of 4 ft. pitch.
Lieblich flute	Wood or metal; "sweet" flute.
Wald flute	Wood; a species of clarabella.

2 ft. tone, i.e. sounding two octaves higher

Fifteenth . . .	Metal; open.
Piccolo . .	Metal or wood; open.
Flautina	Metal; a species of fifteenth.

Mutation stops are those which give a different sound than octaves and doubles to that played, such as the Twelfth, which is of metal, and sounds the twelfth note above. Compound stops are those which have more than one pipe to each key, such as the Mixture of different ranks. *See* MIXTURE. All the above stops are called the FLUEWORK. The late Dr. E. J. Hopkins says: "All organ stops in which the sound is produced by the wind passing through a flue or windway and striking against an edge above, belong to the fluework, whatever may be the shape, make, or tone of their pipes" (Sir George Grove's *Dictionary of Music and Musicians*). The accompanying illustration (fig. 4) shows a metal

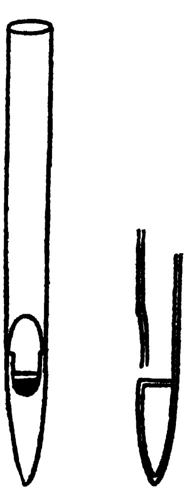

FIG. 4.

FIG. 5.

pipe and a sectional view of the same; fig. 5 shows a stopped wooden pipe and a sectional view of the same. The Reeds are the Double Trumpet, Trombone, and Contra fagotto of 16 ft. tone; the Trumpet, Posaune, Cornopean, Horn, Oboe, Clarionet of 8 ft. tone; and the Clarion of 4 ft. tone. With the exception of the three 16 ft. reeds, which are made of metal or wood, these are all metal pipes. The accompanying illustration (fig. 6) shows a reed pipe with and without the "boot." In the Town Hall, Sydney (N.S.W.), organ, which is the largest in the world, having 5 manuals with 28 stops on the great, 24 on the swell, 20 on the choir, 20 on the solo, 8 on the echo, and 26 on the pedal, besides 14 couplers, there is on the pedal organ a unique 64 ft. reed (contra trombone), the longest tongue being 2 ft. This organ contains 10,250 pipes, weighs 100 tons, and was built by Messrs. W. Hill & Son, London. Besides the above stops, there are the *vox angelica*, which consists of two ranks of pipes of the dulciana type, one of which is tuned sharper or flatter than the other; the *voix celestes*, or *unda maris*, which consists of two ranks of the gamba type tuned like the *vox angelica*. The *vox humana* is a reed of very small length, capped, and is always used with the tremulant. The tremulant acts on the supply of wind in such a manner as to disturb the steady supply, causing a throbbing sensation. Tremulants are of many patterns.

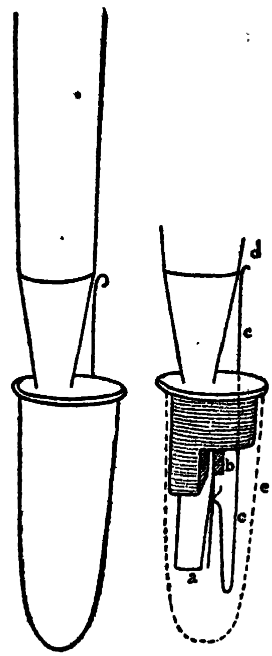

FIG. 6.
(*a*) Reed of hollowed brass, and slightly curved "tongue."
(*b*) Wedge.
(*c*) Tuning spring.
(*d*) Pipe (*e*) The boot.

THE PRINCIPAL PEDAL ORGAN STOPS ARE:

Of 32 ft. tone, i.e. sounding two octaves below.

Contra trombone (reed) .	Wood or metal.
Double open diapason . .	Wood or metal.
Sub-bass or sub-bourdon .	Wood (16 ft. stopped).

Of 16 ft. tone.

Trombone or posaune (reed)	Wood or metal.
Open diapason	Wood or metal.
Violone	Metal (small scale).
Bourdon	Wood (8 ft. stopped).

Of 8 ft. tone.

Trumpet (reed)	Metal.
Violoncello	Metal.
Principal	Metal or wood.
Flute	Wood (or 4 ft. stopped).

Of 4 ft. tone.

Viola or fifteenth . .	Metal.

On some organs, instead of thirty pipes to each stop, an extra octave, making forty-two pipes, is placed to each stop, and an octave coupler added, thus giving a "duplication" of each stop in the octave above at the same time. Another and better plan is to have the forty-two pipes with a separate draw stop to each, one acting on the lower thirty pipes and the other on the upper thirty pipes—*e.g.* bourdon, 16 ft.; flute, 8 ft. In the former case the lowest note on the pedals would open the pallet of the lowest pipe, whilst in the latter the lowest note on the pedal would open the pallet of the octave above, and the highest octave

of the pedals would call into use the extra twelve pipes. The accompanying illustration (fig. 7) shows the lower portion of a pedal open diapason pipe (wood). The ACCESSORY (NON-SPEAKING) STOPS are mechanical contrivances for connecting the different manuals, such as swell to great, swell to choir, solo to great, and cause the corresponding notes of the coupled manual to speak when those notes are played on the manual to which it is coupled. There are also octave (super-octave) and sub-octave couplers, which make the note an octave above or below respectively speak at the same time as the note is depressed. Pedal couplers connect the pedals and manual, and are called great to pedal, choir to pedal, swell to pedal, solo to pedal. COMPOSITION PEDALS consist of iron pedals placed over, but clear of, the pedal board. By varying forms of mechanism these control the stops of the organ, *i.e.* throw them out or in, or out and in, in set combinations. A recent mechanical contrivance enables the organist to arrange the combinations of stops drawn by the composition pedals at the keyboard. This is known as "interchangeable combination." Because these composition pedals, when set, not only throw out the arranged set of draw stops, but at the same time throw in all other stops on the manual to which the pedal belongs, they are known as "double-acting." Composition pedals are generally arranged in progressive order from left to right: (1) *p*; (2) *mf*; (3) *f*; (4) *ff*; those over the lower half of the pedal board acting on the swell organ, those over the upper half acting on the great organ. In some organs, instead of composition pedals, ventils are used, which, until drawn, cut off the wind from certain stops, whether the draw stop is in or out. PNEUMATIC PISTONS are also placed between the manuals (fig. 3) to alter the stops, and have the same effect as composition pedals. When pistons are used some of the composition pedals usually act on the pedal organ stops. Occasionally a crescendo or sforzando pedal is added, which, without altering the stops, brings on the whole of the power of the instrument, either gradually or suddenly, as required. In the Hope-Jones electric organ console, stop keys are placed over the top manual, which when depressed are brought into action, and when raised are thrown out of action. These stop keys are distinguishable by different colours. The nomenclature of the stops, too, is different. The stop keys take the place of draw stops, the latter being entirely done away with. SECOND TOUCH—somewhat similar to the double touch in a Mustel organ (*q.v.*)—is also introduced. Fuller information on the subject can be obtained in *The Organ: Its History and Construction* (Hopkins & Rimbault); *The Art of Organ Building* (Audsley).

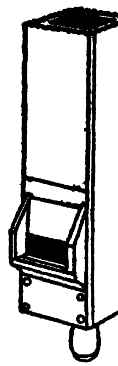

FIG. 7.

The HARMONIUM: This is the most modern of keyed instruments, dating from about 1840 (the American organ, which may be said to be a modified harmonium, was introduced about twenty years later). The harmonium is supplied with compressed wind from a reservoir, which is fitted with a strong spring to resist the expansion caused by the wind supplied to it by feeders worked by the feet of the performer, which are placed on treadles (pedals). The reservoir spring takes the place of the weights on the organ reservoir. A safety valve in the shape of a pallet is placed in the reservoir to minimise over blowing. Above the reservoir is the wind chest, covered by the bellows board, containing valves, which permit the wind to reach the different sets of reeds as the stops are drawn. The reeds are tongues of brass of various thicknesses and lengths, screwed at one end to a metal plate, with apertures over which the tongues vibrate without entirely closing the aperture; hence they are called FREE REEDS, whilst those in the organ are STRIKING REEDS. The apertures are closed by pallets held down by springs, and connected by levers to the keys. When the key is played the pallet is opened, and allows the wind, when a stop is drawn, to pass through the reed aperture at an even pressure, unless a stop called the "Expression" is drawn, which allows the wind to come direct from the feeders. The performer in this case is able to increase or decrease the sound according to the amount of wind supplied by the feet to the feeders. The harmonium has a compass of five octaves, from

whilst that of the American organ is a perfect fifth lower:

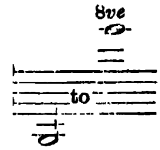
The AMERICAN ORGAN differs chiefly from the harmonium in having the wind drawn in through the reed apertures, whilst in the latter instrument it is blown out. The tone of the former is less harsh than that of the harmonium, which has a more characteristic tone and greater advantages. Harmoniums vary very much in the number of stops. These are placed in three groups: those on the left consisting of sounding and mechanical stops acting on the keys below

those on the right likewise consist of sounding and mechanical stops acting on the keys from and above this note; those in the centre group are mechanical stops only. The two groups of sounding stops are generally similarly numbered, showing which are complementary stops, giving the same quality and pitch throughout the entire keyboard. Some of the most generally found are:

Left hand.	*Right hand.*	*Pitch.*
Cor Anglais, 1.	Flute, 1	8ft. tone. *See* ORGAN.
Bourdon, 2.	Clarionet, 2 .	16 ft. tone.
Clarion, 3.	Fifre or Fife, 3.	4 ft. tone.
Bassoon, 4.	Oboe, 4 . . .	8 ft. tone (reedy).

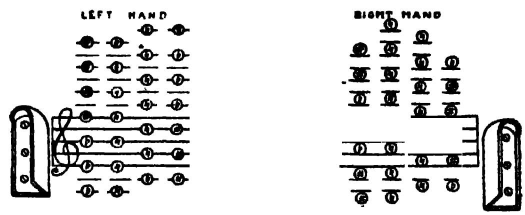
The above is a harmonium with four "sets" of reeds. Other stops are: *Harpe eolienne*, 2 ft. tone, which consists of two half sets of reeds slightly out of tune with each other, producing a waving tone and acting on the lower half of the instrument. *Voix celeste*, 16 ft. or 8 ft. tone, consisting of two half sets of reeds slightly out of tune with each other. *Musette*, 16 ft. tone (reedy). *Barytone*, 32 ft. tone, somewhat like the *musette*. These last three stops act on the upper half of the instrument. The MECHANICAL STOPS are: The *fortes*, which open shutters above the reed box, allowing more sound to escape from whichever half happens to be drawn. *Sourdine*, which shuts off part of the wind on the lower half of the keys, thus giving a softer tone. *Tremolo*, which sets up an unsteady supply of wind. The *Percussions*, which call into play a somewhat similar action to that of the pianoforte, a small hammer striking the Cor Anglais and flute reeds at the moment the key is played, thereby giving an emphasis to the tone. *Grand jeu* (full organ), which when drawn calls into action all the reeds, except the *voix celeste* and *harpe eolienne*, thus giving the full power of the instrument. *Expression*, the most important of the mechanical stops, has been explained above, and gives the performer immense opportunities of bringing out the light and shade of this much neglected instrument. Different *couplers* are also found, and have much the same effect as the couplers on the organ. The result obtainable is placed on the stop label of each. Under the keys knee levers are often fixed. That on the right, when pressed outwards, opens a swell producing a crescendo, whilst that on the left brings into action the *grand jeu*. Sometimes the levers are the reverse of the foregoing, at other times each lever acts as a crescendo on its respective half of the instrument. When there is only one lever it is generally in the middle of the instrument, and brings on the *grand jeu* when pressed to the right, a spring allowing it to recover when the knee is withdrawn. The harmonium has the great advantage of keeping longer in tune than either the organ or pianoforte, and deteriorates very slowly, and deserves much greater attention being paid to it as a solo instrument. An account of the harmonium would be incomplete without a few words concerning the instrument brought to such wonderful perfection by M. Mustel, and bearing his name, "The Mustel organ." On this instrument the percussion is brought to a state of perfection, allowing the most rapid music to be performed, and giving that effect to the stops which "lipping" does to wind instruments. To these organs is also added a *metaphone*, which consists of three Venetian shutters placed immediately over the sound openings of Nos. 3, 4, *musette*, *harpe eolienne*, and *barytone* reeds, softening and refining most of the stops. The metaphones are placed one at each end of the stops. The *double expression* acts on Nos. 3, 4, *musette*, *harpe eolienne*, and *barytone* admitting an extra pressure of wind. This and the expression stops should always be kept out, as the softest tone is instantaneously expressed. Double touch consists of a mechanical arrangement which, when the keys are pressed about a third of the distance down, causes the Nos. 3 and 4 reeds to speak, and when the key is further pressed down, Nos. 1 and 2 reeds also speak. This, it will easily be seen, allows of prominence being given to certain notes only.

The ENGLISH CONCERTINA was invented by Sir Charles Wheatstone (the inventor of the electric telegraph) about 1827. It is an expansible instrument, having a keyboard at each end with the bellows between. The wind from the bellows passes through apertures, causing free reeds to vibrate when a key is pressed. Concertinas are made in different sizes, shapes, and pitch. The treble has from 48 to 64 keys, the compass of one with 56 keys being either from



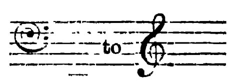
or four octaves from

with all the semitones. The following illustration shows the position of the keys and the sound produced by each in the 56 keyed instrument:

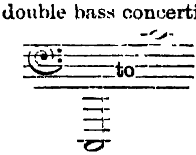


The position of the keys is kept the same in all the family of concertinas. The baritone compass is from

the bass compass is from

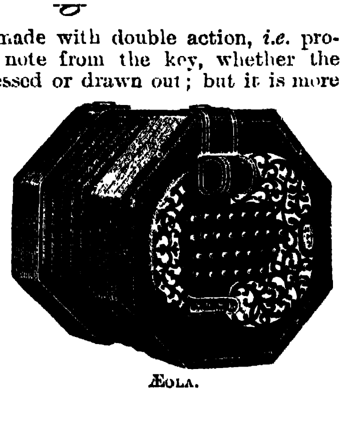


and that of the double bass concertina from



All these can be made with double action, *i.e.* producing the same note from the key, whether the bellows be compressed or drawn out; but it is more usual for the bass and double bass to have a single action.

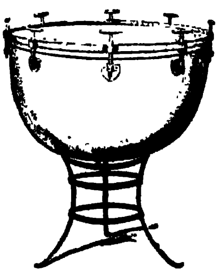
A new instrument of the same family has been brought out by Messrs. Wheatstone & Co., called the ÆOLA. It is octagonal in shape and of remarkably pure



ÆOLA.

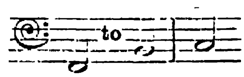
tone. The compass of the different æolas and the fingering are exactly the same as in the corresponding concertina. The best reeds are of highly tempered steel. Concertinas and æolas are now tuned on the equal temperament system, like other keyed instruments, and both brilliant scale passages and chords can be easily performed. A great quantity of music has been composed for this instrument, which is capable of producing combined sustained and staccato passages and giving fine effects of expression. A quartette of concertinas or æolas have between them nearly as extended a compass as a pianoforte.

INSTRUMENTS OF PERCUSSION are of two kinds: (A) Those giving a definite sound, comprising the kettle drums or tympani, the glockenspiel, the key harmonica, and handbells. (B) Those giving an indefinite sound, and used only for marking the rhythm, comprising the bass drum, the side drum, the tambourine, the cymbals, and the triangle.

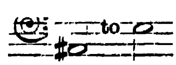


KETTLE DRUM.

(A) The KETTLE DRUMS or TYMPANI are the most important of the percussion instruments, and consist of a metal shell, hemispherical in shape, with a head of vellum, held tightly in position by an iron ring, to which are attached screws to tighten or relax the vellum, thus tuning to any note within its compass. In the orchestra two or more drums are used, the larger having a chromatic compass from

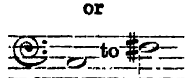


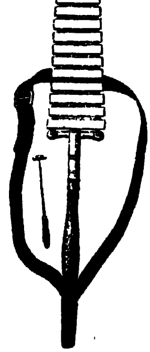
the medium from



and the smaller a chromatic compass from

or

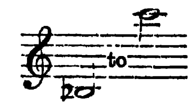




GLOCKENSPIEL AND BEATER.

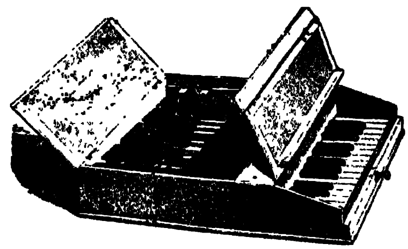
The vellum head is struck by a flexible wooden drumstick with ends of felt or sponge. It is usual now to write the actual notes to be played on the bass stave, but omitting the sharps or flats. The correct tuning, however, must be shown in the directions given at the beginning of, or during, the piece to be performed. Formerly the notation was always in the key of C.

The GLOCKENSPIEL or CARILLON is an instrument consisting of plates of steel, played by striking with beaters or by hammers set in motion by an action similar to the pianoforte. Originally a set of bells instead of steel plates were used. Its compass is from about

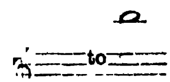


including all the semitones. The illustrations show a glockenspiel with beater and one with pianoforte action.

The KEY HARMONICA is similar to the glockenspiel, but the notes consist of plates of glass. Its compass is from about

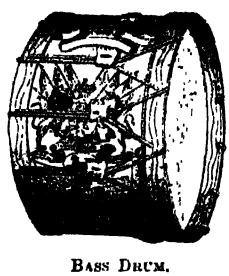


GLOCKENSPIEL OR CARILLON WITH PIANOFORTE ACTION.



HANDBELLS are hollow instruments made of metal, consisting of copper and tin, with at times small quantities of zinc, lead, silver, and antimony, struck by a clapper within, properly pegged to facilitate ringing. They are tuned to the chromatic scale, and a set ranges from 15 (two octaves) to 50 (four octaves).

(B) The BASS DRUM is a large cylinder with a skin head at each end, held in position by hoops. These skins are tightened by means of an endless cord passing round the instrument from hoop to hoop, and drawn together by leather braces. It is played by striking either or both heads with a wooden drumstick, the head of which consists of a series of layers of thick felt in the shape of a ball.

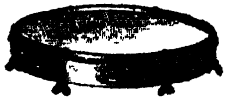


BASS DRUM.

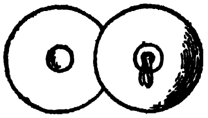
SIDE DRUM.

The SIDE DRUM is a wooden or brass cylinder with a skin head at each end, as in the bass drum. It is played by striking the upper head, called the "batter," with two wooden drumsticks, the heads of which are uncovered. Across and outside the lower head passes a piece of gut called the "snare," four or more times across. When the upper head is beaten by the drumstick, the air in the cylinder is forced against the lower head, thus causing the snare to vibrate on the lower head, and give a sharp, crisp sound.

The TAMBOURINE: A wooden hoop with only one head of vellum, with metal "jingles" in pairs inserted at intervals round the hoop, which rattle when the instrument is shaken or played. There are two ways of playing the tambourine—one by striking it with the hand, the other by rubbing the vellum with the thumb or finger.



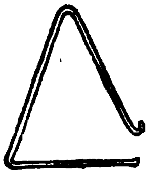
TAMBOURINE.



CYMBALS.

The CYMBALS: A pair of thin metal plates, somewhat of the shape of plate covers, which the player holds by a strap of leather running through the centre, one in each hand. They should be played by sliding one against the other, but not infrequently—although decidedly detrimental to the tone—one is fastened to the bass drum and the other held by the drummer in his left hand, and struck against it whilst playing the drum with the right hand.

The TRIANGLE: A rod of steel in the shape of a triangle, but with one angle not joined. It is played by striking it with a steel "beater."



TRIANGLE AND BEATER.

The division of the musical instruments into orchestral and military is shown under SCORE (*q.v.*) A drum and fife band generally consists of F piccolos, B♭ flutes, third flutes, side drums, bass drum, triangle, with the addition at times of cymbals, half the number in the band playing B♭ flutes.—W. W.

Musical Interval. *See* INTERVAL.

Musical Ornaments. *See* ORNAMENTS (MUSIC).

Musk (*Zool.*) An aromatic substance secreted in a glandular sac on the abdomen of the Musk Deer (*Moschus moschifera*), a native of the Himalayas and Central Asia.

Musket (*Arms*). *See* MUSQUET.

Musketoon (*Arms*). A rather short form of musquet (*q.v.*), with a wide bore; often bell-mouthed.

Musquet (*Arms*). A matchlock gun which succeeded the arquebus as a hand gun in the latter half of the sixteenth century, and was fired from the shoulder.

Mustard (*Botany*). The Cruciferous plants *Brassica nigra* (Black Mustard) and *B. alba* (White Mustard) yield the condiment, which consists of the ground seeds. Both species are common to Central and Southern Europe, and are also found in Southern Britain.

Mustard Oils (*Chem.*) The esters of isothiocyanic acid, CSNH. The most important of these is allyl isothiocyanate, $CSN.CH_2.CH:CH_2$, a colourless liquid having a very pungent smell, which causes tears; it blisters the skin; boils at 151°. Boiled with hydrochloric acid or heated with water at 200°, it yields allylamine.

$$CSNC_3H_5 + 2H_2O = CO_2 + SH_2 + C_3H_5NH_2.$$

It is prepared by distilling allyl iodide with an alcoholic solution of potassium thiocyanate. The natural oil of mustard is nearly pure allyl isothiocyanate. It is obtained from black mustard seeds, which are freed from oil by pressure, and made into a paste with water; now an aqueous extract of white mustard seeds is added. The black mustard seeds contain a glucoside called potassium myronate and also myrosin, an enzyme which hydrolyses the glucoside; the aqueous extract of white mustard seeds also contains myrosin. The reaction is:

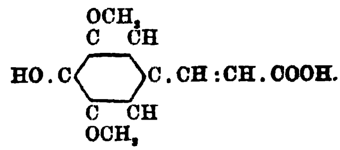
$$\underset{\text{Potassium Myronate (Sinigrin).}}{C_{10}H_{18}KNS_2O_{10}} = CSNC_3H_5 + KHSO_4 + \underset{\text{Glucose.}}{C_6H_{12}O_6}$$

White mustard seeds contain the glucoside sinalbin, which is hydrolysed by the enzyme myrosin as follows:

$$C_{30}H_{44}N_2S_2O_{16} = \underset{\text{Paraoxybenzylisothiocyanate (Sinalbin Mustard Oil).}}{CSNCH_2C_6H_4OH} + C_6H_{12}O_6$$

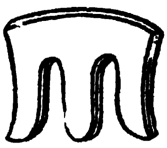
$$+ \underset{\text{Sinapine Sulphate.}}{C_{16}H_{24}NO_5HSO_4.}$$

Sinapine is a compound of choline (*q.v.*) and hydroxy-4-dimethoxy-3 : 5-cinnamic acid.

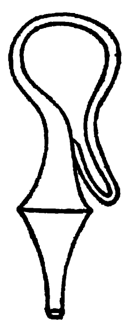


Mutation Stops (*Music*). Those stops in an organ which give a different note (not octaves or doubles) from that played. *See* ORGAN.

Mute (*Music*). An instrument for deadening the sound in musical instruments. In the violin family it is made of different materials, and of various shapes, and is slotted in order that it can be fixed on the bridge; in the pianoforte the soft pedal acts as a mute. *See* SORDINI. Brass instruments are muted by a kind of leathern pear inserted into the bell, or by an additional valve which directs the column of air into a special bell, which has in its centre a chamber formed of two reversed cones with a small outlet at one end. The sound, being turned into the two reversed cones, comes out from the small aperture in a muted manner.



VIOLIN MUTE.



CORNET MUTE.

Mutual Induction (*Elect.*) The passage of lines of force through one circuit due to a current flowing through a second circuit. If a unit current flowing in one circuit causes l lines of force to pass through w turns of the second circuit, then $l \times w$ is called the COEFFICIENT of MUTUAL INDUCTION of the two circuits, and is denoted by M. Its value is the same whichever circuit the unit current flows in.

Mutule (*Architect.*) A projecting block worked on the soffit of the corona of the Greek, and sometimes of the Roman, Doric entablature. A number of guttæ are usually worked on the underside of each mutule. In Greek work there is usually a mutule over each triglyph and metope, the width of the mutule being equal to that of the triglyph; but in the Roman Doric order the mutules over the

metopes are omitted. *See* DORIC ORDER, ENTABLATURE, *and* ARCHITECTURE, ORDERS OF.

Muzzled (*Her.*) When an animal, *e.g.* a bear, is muzzled; if the muzzle is of a different colour it must be given.

Myrobalan (*Botany*). The astringent fruits of *Terminalia chebula* and *T. belerica* (order, *Combretaceæ*), trees growing in the mountainous districts of India. The fruit, which is a juiceless drupe, is extensively used in tanning and dyeing, and to some extent in medicine.

Myrrh (*Botany*). A gum resin obtained by exudation from the stem of a spiny shrub *Balsamodendron myrrha* (order, *Burseraceæ*). It is imported from Abyssinia and Arabia. Used in medicine and as an aromatic.

Myrtle. *See* WOODS.

N (*Elect.*) (1) The symbol for North or for the north seeking pole of a magnet. (2) A symbol often used for the magnetic flux (*q.v.*)

n (*Elect.*) A symbol often used for Frequency (*q.v.*)

Nadir (*Astron.*) A point or, more correctly, a direction immediately beneath the observer, and opposite to the zenith (*q.v.*)

Nagyagite (*Min.*) A telluride and sulphide of lead and gold. Also called black tellurium: orthorhombic. It usually contains some antimony, and the gold varies from 6 to 12 per cent. It is a dark lead grey sectile mineral. From Transylvania.

Naiant (*Her.*) A fish swimming straight across the field.

Nail Head (*Architect.*) A Norman moulding enriched with a series of pyramidal forms resembling nail heads.

Naissant *or* **Issuant** (*Her.*) An animal rising or issuing from the middle of an ordinary.

Naked Eye (*Astron.*) When an object is observed without any aid, such as glasses, it is said to be observed with the naked eye.

Naked Floor (*Carp. and Join.*) The floor joists without the boards.

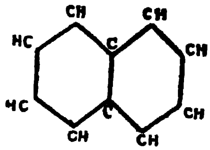
Naked Forme (*Typog.*) A form that has been stripped of its furniture (*q.v.*) preparatory to distributing the type, or one around which the furniture has not yet been placed.

Naos (*Architect.*) *See* CELL.

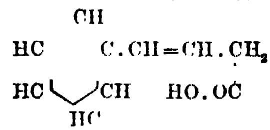
Nap (*Textile Manufac.*) A heavy cloth of the frieze character used for overcoatings; but the naps or curls of fibres are more dense than in the frieze. *See* NAPPING.

Naphtha (*Chem.*) A term originally applied to rock oil, that is, oil issuing from the earth; then it was applied to fractions of these oils boiling up to 170°, or about that. Now it is applied at random to mixtures of hydrocarbons and other compounds from the most varied sources; *e.g.* bone naphtha from bone oil, solvent naphtha from wood tar, mineral naphtha from petroleum.

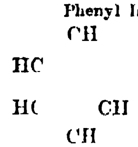
Naphthalene (*Chem.*)



A white solid which crystallises in plates; melts at 80°; boils at 218°; readily volatilises; distils in steam; insoluble in water; soluble in all the ordinary organic solvents, such as alcohol, ether, benzene, toluene, acetic acid. It has a characteristic smell, and is a valuable antiseptic, and is very objectionable to many insects—hence its use in preserving clothes and skins from the ravages of moths, etc. Technically it is used in the preparation of many dyes, *e.g.* Congo red, indigo, and many others (*see* under the various naphthalene derivatives); in increasing the illuminating power of coal gas, as in the albo carbon light, where coal gas is made to pass over melted naphthalene, and of water gas. It is obtained from coal tar, which contains 8 to 10 per cent. of it: for the method *see* GAS MANUFACTURE. Naphthalene derivatives have been synthesised from benzene derivatives by methods which show that naphthalene must have the constitution given in the above formula; *e.g.* if benzaldehyde is heated with sodium succinate and acetic anhydride at 125°, PHENYL ISOCROTONIC ACID and PHENYL PARACONIC ACID are obtained: these can be separated by carbon disulphide, in which the former is soluble.

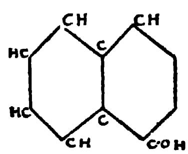


Phenyl Isocrotonic Acid.

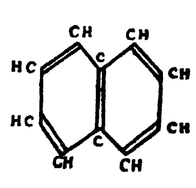


Phenyl Paraconic Acid (this acid really forms the lactone).

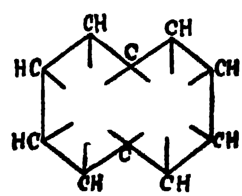
The former on long boiling with water gives α-NAPHTHOL—



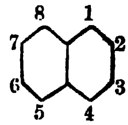
The formula given for naphthalene above is the one which will be used in describing the naphthalene derivatives: it does not account for the fourth combining unit of each of the carbon atoms. Two formulæ are in use for this purpose:



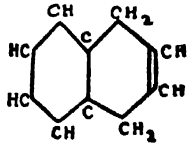
and



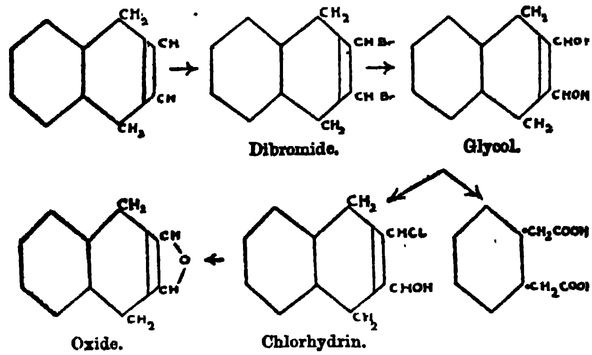
The latter is known as the CENTRIC FORMULA. In naming naphthalene derivatives the carbon atoms are numbered as shown:



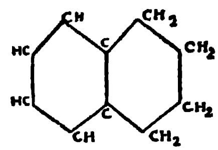
Other systems are in use: (1) The atoms numbered 1, 4, 5, 8 are often denoted by the letter α, and when it is desired to distinguish between them they are denoted respectively by α_1, α_2, α_3, α_4. The atoms numbered 2, 3, 6, 7 are often denoted by the letter β, and when it is desired to distinguish between them they are denoted respectively by β_1, β_2, β_3, β_4. (2) The atoms 1, 2, 3, 4 are numbered as above, but the atoms 8, 7, 6, 5 are numbered respectively 1^1, 2^1, 3^1, 4^1. On this system 1 : 8 dinitronaphthalene would be $1:1^1$ dinitronaphthalene. (3) The 1 : 8 di-derivatives are often called peri-derivatives; so also the 4 : 5, which are similarly situated to the 1 : 8. Peri-derivatives behave like ortho-derivatives, *i.e.* like 1 : 2 or 2 : 3 derivatives. A glance at the formula for naphthalene will show that mono-substitution products can exist in two forms, an α-form or a β-form. Thus if one hydrogen be replaced by a hydroxyl group we shall get one compound called α-naphthol if the hydroxyl group takes any of the positions 1, 4, 5, 8, for all these are similarly situated; and we shall get another compound called β-naphthol if the hydroxyl group takes any of the positions 2, 3, 6, 7, for all these are similarly situated. It will also be seen that ten di-derivatives are possible when the substituting group is the same—that is to say, there are ten dihydroxynaphthalenes; but there are fourteen if the substituting groups are different—there would be fourteen hydroxynaphthylamines, $C_{10}H_6OHNH_2$. In its chemical behaviour naphthalene bears considerable resemblance to benzene: it forms addition products with hydrogen, addition products and substitution products with chlorine and bromine; it can be nitrated and sulphonated like benzene. Homologues can be prepared by the methods of Fittig and Friedel and Crafts (*q.v.*) Its substitution products behave in general like those of benzene, but the substituents are more easily removed. The more important addition products and the halogen substitution products will be briefly described here, the remaining substitution products separately. Naphthalene can unite with two, four, six, eight, ten, or twelve hydrogen atoms, but only two of these need be mentioned. DIHYDRONAPHTHALENE—



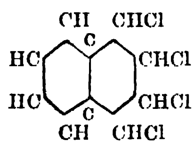
is a solid; melts at 15°; boils at 212°. It resembles ethylene in its chemical properties to a remarkable extent. Like ethylene it forms a dibromide by direct union with bromine, and the dibromide is hydrolysed by potassium carbonate to a substance like glycol-orthohydronaphthyleneglycol. The latter yields a chlorhydrin with hydrochloric acid, and the chlorhydrin with an alkali gives tetrahydronaphthyleneoxide corresponding to ethyleneoxide. The glycol on oxidation with chromic acid gives orthophneylenediacetic acid—



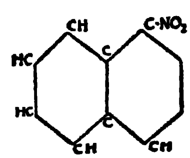
The dihydronaphthalene is obtained by reduction of a boiling solution of naphthalene in alcohol by sodium. TETRAHYDRONAPHTHALENE—



is an oil which turns brown in air; boils at 206°; is obtained by adding sodium to a solution of naphthalene in isoamyl alcohol. NAPHTHALENE TETRACHLORIDE—

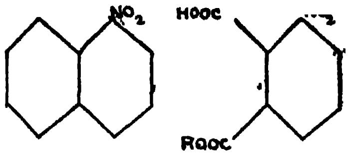


Crystallises in prisms, melts at 182°, and sublimes at 225°; soluble in benzene; when oxidised with strong nitric acid, it gives phthalic acid. It is obtained by passing chlorine into a chloroform solution of naphthalene, or by treating the latter with potassium chlorate and strong hydrochloric acid. α-CHLORNAPHTHALENE, $C_{10}H_7Cl$, is a liquid which boils at 263°. It is obtained by leading chlorine into boiling naphthalene, and by the action of phosphorus pentachloride on α-nitronaphthalene or on α-naphthalene sulphonic acid; also by the diazo-reaction from α-naphthylamine. β-CHLORNAPHTHALENE melts at 57°, and boils at 265°. It is obtained by the action of phosphorus pentachloride on the β-nitro and sulphonic acid derivatives, and by the diazo-reaction from β-naphthylamine. All the ten dichlornaphthalenes are known. NAPHTHALENE NITRO DERIVATIVES, α-NITRONAPHTHALENE—

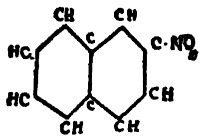


Crystallises in yellow needles; melts at 61°; boils at 304°. On reduction it yields α-naphthylamine. On

oxidation with chromic acid in acetic acid it yields vicinal nitro-phthalic acid

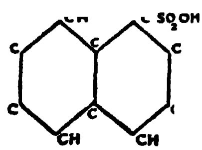


It is obtained by acting on naphthalene (5 parts) with a mixture of nitric acid (4 parts) and sulphuric acid (16 parts) at 40 to 50°, or by shaking naphthalene with nitric acid in the cold from time to time during three weeks, and crystallising the product from alcohol. β-NITRONAPHTHALENE—

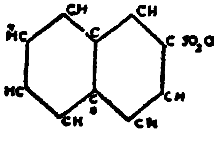


Crystallises in yellow needles; melts at 79°; is volatile in steam; readily soluble in alcohol. It is obtained by treating β-diazonaphthalene nitrite from β-naphthylamine, with precipitated cuprous oxide. 1 : 5 dinitronaphthalene; yellow needles; melts at 216°. To obtain it 100 grs. of naphthalene and 310 cc. of nitric acid are allowed to stand for twenty-four hours. Then 160 cc. of sulphuric acid are added, and the mixture heated on a water bath for a day. The acid is poured off, residue washed and dried and extracted with carbon disulphide, then repeatedly extracted with acetone to separate 1 : 8 dinitronaphthalene. It is now crystallised from xylene. For its use *see* NAPHTHYLAMINES *and* NAPHTHAQUINONES.

Naphthalene Sulphonic Acids (*Chem.*) α-naphthalene sulphonic acid—

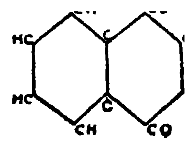


A crystalline deliquescent solid; melts at 85 to 90°. Heated with sulphuric acid, it is transformed to naphthalene-β-sulphonic acid; heated with hydrochloric acid at 200°, it is resolved into naphthalene and sulphuric acid. On fusion with caustic soda it yields α-naphthol; its sodium salt with phosphorus pentachloride gives the chloride $C_{10}H_7SO_2Cl$ (MP66°). It is prepared by heating naphthalene with its own weight of sulphuric acid at 90° for about three hours. The product is poured into water, separated from unchanged naphthalene, neutralised with chalk, filtered and concentrated, when calcium naphthalene-β-sulphonate separates. The mother liquor gives the calcium salt of the α-acid on further concentration. The acid is set free by addition of sulphuric acid. β-Naphthalene sulphonic acid—



Crystallises in plates; not deliquescent; melts about 101°; not decomposed at 200° by hydrochloric acid. Its sodium salt with phosphorus pentachloride gives the acid chloride $C_{10}H_7SO_2Cl$ (M P76°); fused with caustic soda it gives β-naphthol. It is prepared by heating naphthalene with its own weight of sulphuric acid at 180° for six hours; the product is poured into water, and on adding salt the sodium salt separates. The free acid can be obtained by making the calcium salt instead of the sodium salt and decomposing it by sulphuric acid. The acid can be hydrolysed by distilling in superheated steam with dilute sulphuric acid at 135°. When the sodium salt of this acid is further sulphonated, it yields the 1 : 6 disulphonic acid. The 1 : 5 disulphonic acid is obtained from naphthalene (1 part) and fuming sulphuric acid containing 30 per cent., SO_3 (4 parts), at a low temperature. The 2 : 6 disulphonic acid is obtained from naphthalene and sulphuric acid (1 to 5) at 180° for twenty-four hours. The disulphonic acids, which cannot be obtained by direct sulphonation, are obtained from the naphthylamine sulphonic acids. These acids are largely used in the preparation of other naphthalene derivatives. For instance, when the α-acid is nitrated and then reduced, a mixture of 1 : 8-α-naphthylamine sulphonic acid and the 1 : 5 acid is obtained, and these can be separated by means of their sodium salts, the salt of the former being much less soluble in water than that of the latter.

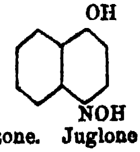
Naphthaquinones (*Chem.*) α-Naphthaquinone—



A yellow crystalline solid; melts at 125°, but begins to sublime below 100°; characteristic quinone smell; readily soluble in alcohol, ether, benzene; distils in steam. It is prepared by oxidising a solution of naphthalene in glacial acetic acid by chromic acid in 80 per cent. acetic acid. The mixture is left for three days, during which it is shaken from time to time; the naphthaquinone separates on addition of water, and is crystallised from petroleum ether. It is also obtained by oxidation of α-naphthylamine by potassium dichromate and dilute sulphuric acid in the cold. On reduction with zinc and hydrochloric acid it gives 1 . 4 dihydroxynaphthalene; on oxidation with nitric acid it gives phthalic acid; forms addition products with one molecular proportion of bromine or chlorine, which readily lose halogen acid:

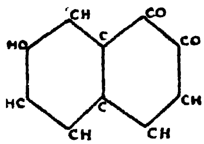
$$C_6H_4\left\langle\begin{array}{l}CO-CH\\ \quad\;\;\;\|\\ CO-CH\end{array}\right. \rightarrow C_6H_4\left\langle\begin{array}{l}CO-CHBr\\ \quad\;\;\;|\\ CO-CHBr\end{array}\right. \rightarrow C_6H_4\left\langle\begin{array}{l}CO-CBr\\ \quad\;\;\;\|\\ CO-CH\end{array}\right. .$$

With primary amines substitution products are formed on heating, *e.g.* with aniline 2-anilido-α-naphthaquinone, $C_{10}H_5O_2NHC_6H_5$, which is red; with hydroxylamine it forms α-nitroso-α-naphthol,



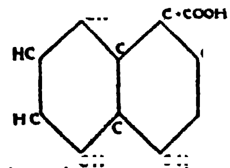
with phenylhydrazine it gives a hydrazone. Juglone

(*q.v.*) is 5-hydroxy-α-naphthaquinone. Naphthazarin is 5 : 6-dihydroxy-α-naphthaquinone. It is a lustrous brown crystalline (needles) solid, which sublimes on heating; soluble in alcohol and glacial acetic acid; dissolves in strong sulphuric acid with a red colour, and in alkalis with a blue colour. Its sodium bisulphite compound is used as a black dye, Alizarine Black. It is prepared by heating 1 : 5 dinitronaphthalene with concentrated sulphuric acid, and adding zinc from time to time; then the product is diluted with water and filtered. The naphthazarine, which separates on cooling, is purified by solution in alkali and precipitation with acid. It is also prepared by electrolysing the mixture of 1 : 8 and 1 : 5 dinitronaphthalenes obtained on direct nitration of the hydrocarbon in strong sulphuric acid at 130°, pouring the product into water at 0°, filtering, and boiling for an hour (D.R.P. 79,406). β-naphthaquinone,



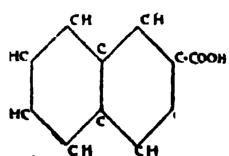
Red needles; decomposes at 115 to 120°; no smell; not volatile in steam; soluble in alcohol, ether, acetic acid, benzene. It is prepared by oxidising a solution of α-amido-β-naphthol hydrochloride in solution in water containing some sulphurous acid by means of ferric chloride solution; the quinone separates, and it is washed and dried. The α-amido-β-naphthol is obtained from β-naphthol by action of nitrous acid, which gives α-nitroso-β-naphthol, and the latter on reduction with ammonium sulphide gives α-amido-β-naphthol. Many of its reactions are similar to those of α-naphthaquinone; *e.g.* on reduction it gives 1 : 2 dihydroxynaphthalene: on oxidation it gives phthalic acid; it adds bromine and chlorine in the same way; behaves in the same way towards hydroxylamine and phenylhydrazine.

Naphthoic Acids (*Chem.*) These are the naphthalene analogues of benzoic acid. α-Naphthoic Acid crystallises in white needles; melts at 162°; sparingly soluble in water; soluble in alcohol; heated with soda lime, it gives naphthalene; on nitration it yields a mixture of the 1 : 5 and 1 : 8 nitro-α-naphthoic acids; on oxidation with chromic acid in glacial acetic acid, it gives phthalic acid. It is obtained by hydrolysis of its nitrile, and the latter can be obtained by distilling sodium naphthalene-α-sulphonate with potassium cyanide or ferrocyanide. It is also obtained fusing potassium naphthalene - α - sulphonate with sodium formate.

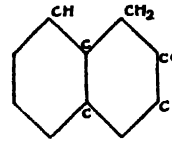


α-naphthoic acid

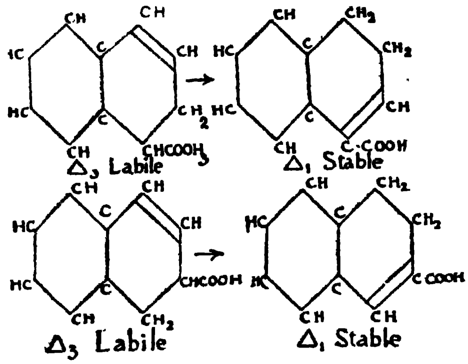
β-Naphthoic Acid: white needles; melts at 185°; sparingly soluble in water; very soluble in alcohol; reactions with soda lime and chromic acid are the same as the α-acid; on nitration it yields five nitro-β-naphthoic acids. It is obtained by hydrolysis of its nitrile, and the latter is formed from the sodium β-sulphonate just as with the α-acid. Both acids yield hydroxy-acids, which are analogous to the hydroxy-benzoic acids. These hydroxy-acids can be obtained by heating the sodium salt of the two naphthols in carbon dioxide, just as salicylic acid is obtained from the sodium salt of phenol. From the sodium salt of β-naphthol treated with carbon dioxide at 120° to 145°, the carboxyl group enters at position 1; but at 200° to 250° the carboxyl group enters at position 3. This last acid has a yellow colour, and on this account this formula has been suggested for it:



β naphthoic acid

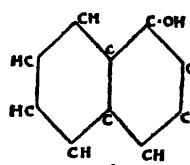


The acids (OH – 1 : COOH – 2) : (OH – 2 : COOH – 1) : (OH – 2 : COOH – 3) all colour ferric chloride solution blue. Both naphthoic acids on reduction with sodium amalgam give dihydronaphthoic acids, the hydrogen entering the substituted ring. When the reduction is effected in the cold, labile forms are obtained which pass on warming with caustic soda partly into more stable forms:



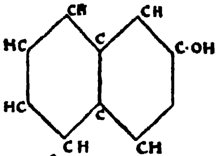
Naphthol Black. *See* Dyes and Dyeing.

Naphthols. α-Naphthol: white shining needles; melts at 94°; boils at 279°; smells like phenol; readily soluble in alcohol, ether, benzene; sparingly soluble in water; volatile in steam. It can be obtained by the diazo-reaction from α-naphthylamine, but is obtained on the large scale by heating sodium naphthalene - α - sulphonate with caustic soda, acidifying the product and distilling. Its synthesis is given under naphthalene. With caustic soda the hydroxyl hydrogen is replaced by sodium, giving sodium naphtholate; with ferric chloride it gives a violet precipitate of dinaphthol; yields a nitroso-compound (*q.v.*) with nitrous acid; on reduction with sodium and amyl alcohol it forms ar-tetrahydro-α-naphthol (*see under* Naphthylamines), which melts at 69°. On nitration it gives the dinitro-α-naphthol, OH1 : 2 : 4, which resembles picric acid. The sodium salt is the yellow dye Martius yellow, also called naphthol yellow.



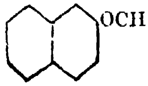
α naphthol

β-NAPHTHOL: white shining scales; melts at 122°; boils at 286°; smells like phenol; readily soluble in alcohol, ether, benzene, hot water; soluble in olive oil (1 in 8); powerful antiseptic, and is on this account used in medicine. Obtained like α-naphthol, using β-naphthylamine or sodium naphthalene-β-sulphonate. Reacts

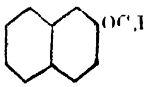


β naphthol

with caustic soda like α-naphthol; also with ferric chloride, but the coloration is green: also with nitrous acid; on reduction with sodium and amyl alcohol it yields ac- and ar-tetrahydro-β-naphthol; the former boils at 264°, and the latter melts at 58° and boils at 275°. Both naphthols form ethers. The β-naphthol methyl and ethyl ethers—



M.P. 70°, B.P. 274°, and



M.P. 37°, B.P. 274,

are obtained by heating β-naphthol with methyl and ethyl alcohol, as the case may be, and concentrated sulphuric acid at 125°. They are both used in making perfumes: the former smells like neroli oil (the oil from flowers of the bitter and sweet orange); the latter, also known as Bromelia, has an acacia-like smell. Both naphthols combine with diazo-compounds: α-naphthol takes on the diazo-compound at position 4, or, if this is occupied, at position 2, while β-naphthol takes it on at position 1, or, if this is occupied, at position 3. Many of these azo-compounds are dyes. Examples: *see* FAST RED (ROCELLINE) *and* FAST BROWN *under* NAPHTHYLAMINES: here the diazo-compound is that of naphthionic acid. BIEBRICH SCARLET is obtained from β-naphthol and amidoazobenzene disulphonic acid; it is

$$NaOO_2SC_6H_4 . N = N . C_6H_3\begin{cases} SO_2ONa \\ N \end{cases}$$

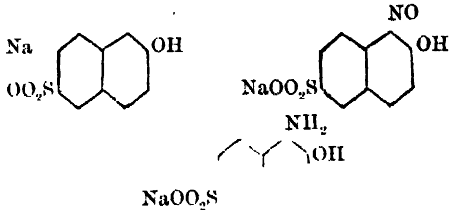
Both naphthols yield a large number of sulphonic acids, which are used in making dyes. α-naphthol-sulphonic acid, NW (1 : 4), is obtained by diazotising naphthionic acid and boiling with dilute sulphuric acid, or by heating sodium naphthionate with a solution of caustic soda under pressure: white crystals; melts at 170°; soluble in water. ORSEILLINE (BB) is an example of a red dye obtained from this acid by treating with diazotised amidoazotoluene-monosulphonic acid; it has the formula

$$\begin{matrix} CH_3 \\ NaO . O_2S \end{matrix}\Big\rangle C_6H_3 . N_2 . C_6H_3(CH_3)—N_2—C_{10}H_5\Big\langle\begin{matrix} {}^1OH \\ {}_4SO_2ONa \end{matrix}$$

β-naphthol sulphonic acid (2.6) is obtained by heating β-naphthol with twice its weight of concentrated sulphuric acid at 100°; on adding water and salting out its sodium salt crystallises. This acid is used in making the dye BRILLIANT ORANGE (Ponceau 4 GB) by allowing it to act on diazotised aniline. The dye has the formula

$$C_6H_5—N : N—\overset{1}{C_{10}}H_5\overset{2}{O}H . SO_2^6ONa.$$

The photographic developer EIKONOGEN is prepared from this acid by acting on one of its salts with sodium nitrite and hydrochloric acid, and reducing the nitroso-compound thus formed by stannous chloride:



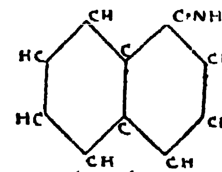
Eikonogen.

It can also be obtained by reducing the above dye (Ponceau 4 GB) by stannous chloride. Nine of the ten theoretically possible dioxynaphthalenes are known. Several trioxynaphthalenes are known. The 1 : 4 : 5 compound is α-hydrojuglone. *See* JUGLONE *and* NAPHTHAQUINONES.

Naphthol Yellow. *See* DYES AND DYEING.

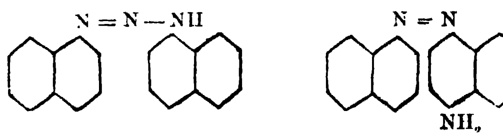
Naphthyl (*Chem.*) The name given to the residue remaining when one hydrogen atom is removed from the naphthalene molecule. The residue when a hydrogen atom is removed from an α-position is called α-naphthyl; when it is removed from a β-position it is called β-naphthyl. *See* NAPHTHYLAMINES.

Naphthylamines. α-NAPHTHYLAMINE: white solid; crystallises in flat needles; melts at 50°; boils at 300°; turns red in air; unpleasant smell; easily volatile; insoluble in water; readily soluble in alcohol, ether, aniline. It is obtained by reducing α-nitronaphthalene with tin and hydrochloric acid, or, on the large scale, with iron in place of tin. It is a base, and



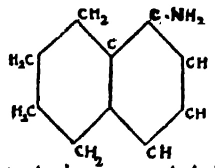
α-naphthylamine

forms salts with acids; solutions of its salts give a blue precipitate with oxidising agents, *e.g.* with chromic acid. Its salts give the diazo-reaction with nitrous acid, and diazo-naphthalene-sulphate gives α-naphthol on boiling with dilute acid. The diazo-chloride, treated with α-naphthylamine hydrochloride in the cold and alkaline solution, gives diazoamidonaphthalene, which undergoes intramolecular change to α-AMIDO-AZONAPHTHALENE—



The latter compound, on heating with α-napthylamine hydrochloride in glacial acetic acid solution, gives the dye Magdala red or naphthalene red. Its alcohol solution has splendid yellow fluorescence. A solution of α-naphthylamine in dilute acetic acid, when mixed with a solution of sulphanilic acid, constitutes an extremely delicate test for nitrous acid or a nitrite (1 in 100,000,000). This depends on a similar reaction to the above, α-naphthylamine-azobenzene sulphonic acid being formed, $C_6H_4SO_2OH . N_2C_{10}H_6NH_2$, which gives a beautiful red colour in

acid solution. On reduction of α-naphthylamine with sodium in boiling amyl alcohol, four hydrogen atoms are added on to the unsubstituted nucleus, forming ar-TETRAHYDRO-α-NAPHTHYLAMINE (ar- is an abbreviation of aromatic, and may be taken to mean that the substituted ring acquires a true aromatic character); a liquid; boils at 275°; a weak base; reduces salts of the noble metals; gives diazo-reaction with nitrous acid; on oxidation it

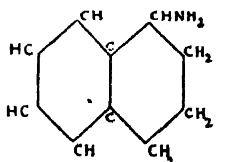


ar-tetrahydro-α-naphthylamine

gives adipic acid,

$$\begin{array}{l} CH_2.COOH \\ H_2C \\ \quad | \\ H_2C \\ CH_2.COOH \end{array}$$

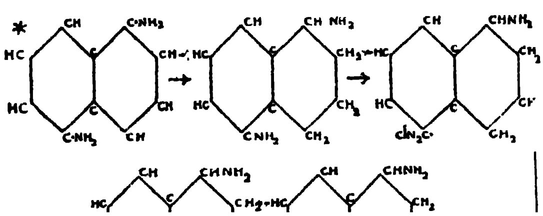
, and oxalic acid. The isomeric ac-TETRAHYDRO-α-NAPHTHYLAMINE (ac- is an abbreviation of alicyclic, and may be taken to mean that the substituted ring acquires the properties of an aliphatic (*q.v.*) substance) is a liquid; boils at 246°; has a smell like piperidine; strong base, taking up carbon dioxide from the air; no reducing properties; with nitrous acid gives crystalline nitrate; on oxidation with potassium permanganate it gives ORTHOCARBOXY-β-PHENYL-PROPIONIC ACID,



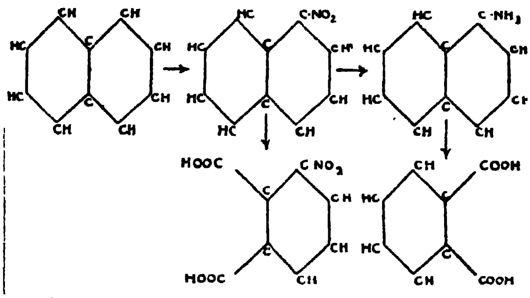
ac-tetrahydro-α-naphthylamine

$$\begin{array}{l} CH \\ HC \quad\; \diagup COOH \\ \quad\;\; | \\ HC \quad\; \diagdown CH_2.CH_2.COOH \\ CH \end{array}$$

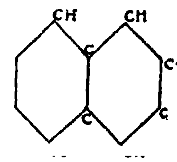
It is obtained from 1:5 naphthylenediamine by reducing with sodium in amyl alcohol, diazotising, reducing to the hydrazine, and warming with copper sulphate solution. The 1:5 diamine is obtained from 1:5 DINITRONAPHTHALENE—



See NITRONAPHTHALENES. When α-naphthylamine is oxidised with potassium dichromate and dilute sulphuric acid it gives phthalic acid and 1:4 napthaquinone, and the latter on further oxidation also gives phthalic acid. As α-nitronaphthalene, from which α-naphthylamine is obtained on reduction, gives nitrophthalic acid, naphthalene must contain two benzene rings, one of which is destroyed when the nitro-compound is oxidised, and the other when the amine is oxidised—



β-NAPHTHYLAMINE: white crystalline scales: melts at 112°; boils at 294°: no smell; soluble in water (solution has blue fluorescence), alcohol, ether; volatile in steam. Obtained by heating β-naphthol with the zinc chloride compound of ammonia ($ZnCl_2.NH_3$) at a high temperature. It is a base; does not give a colour with oxidising agents. Its salts give the diazo-reaction with nitrous acid. On reduction with sodium in boiling amyl alcohol solution, it yields both the ar- and ac-tetrahydro-β-naphthylamines, the latter in larger amount (96 per cent.); they closely resemble the corresponding α-compounds, and boil respectively at 276° and 249°. A very large number of substitution products of the two naphthylamines is known, especially nitro-derivatives and sulphonic acids; they are extensively used in dye making.



β-Naphthylamine

NAPHTHIONIC ACID—

$$\begin{array}{ccc} & CH \quad C.NH_2 & \\ HC & & CH \\ HC & & CH \\ & CH \quad C.SO_2OH & \end{array}$$

a white solid (needles); sparingly soluble in water; obtained by heating α-naphthylamine with concentrated sulphuric acid (4 to 5 parts) at 100 to 110°; is used in the preparation of CONGO RED (*q.v.*), and many other red dyes, *e.g.* FAST RED (rocelline)—

1 2

$_4 \diagdown SO_2ONa$

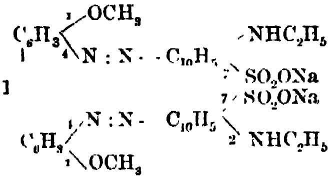
from naphthionic acid and β-naphthol, FAST BROWN N. from naphthionic acid and α-naphthol. When β-naphthylamine is treated with strong sulphuric acid, four different sulphonic acids are obtained, *viz.*

2 : 8 (α-acid), 2 : 6 (β-acid), 2 : 5 (γ-acid), 2 . 7 (δ-acid).

The α- and γ-acids are formed first, and the other two are formed from these at a higher temperature; the β- and δ-acids are important in dye making, and

* This compound, ac-ar-tetrahydronaphthylenediamine, behaves at the same time as an aromatic and an alicyclic amine.

they are more conveniently obtained from the corresponding β-naphthol sulphonic acids by heating with ammonia under pressure. The cotton dye HELIOTROPE may be taken as an example of a dye from the δ-acid: it is obtained from the diazo-compound of dianisidine, and has the formula



Napier's Compasses. Drawing compasses, with legs made to fold up for carrying in the pocket.

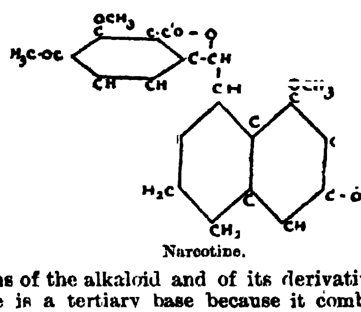
Napkin Pattern. *See* LINEN FOLD.

Naples Yellow (*Dec.*) Most of the yellow sold under this name is a mixture of cadmium yellow with zinc white. True Naples yellow is prepared from oxide of lead and antimony. It is not much used now, having been largely replaced by chrome yellow.

Napping (*Textile Manufac.*) Process of developing the nap by rubbing the raised fibres into small curls, the work being done on the napper or napping machine.

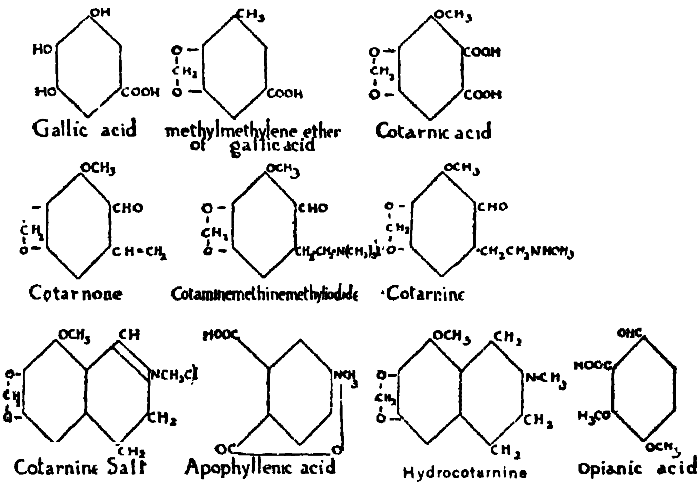
Narcotic. A drug used to produce sleep or deaden pain. Most narcotics are poisonous when taken in large doses.

Narcotine. White needles; melts at 176°; nearly insoluble in water; sparingly soluble in cold alcohol; fairly soluble in boiling alcohol; fairly soluble in benzene; easily soluble in chloroform; strongly lævo-rotatory, but its salts are dextrorotatory; only feebly poisonous, and it has no narcotic action (hence it is sometimes called anarcotine); it is a feeble base, having no action on litmus, its salts being hydrolysed by water, and sodium acetate liberates the base from a solution of narcotine hydrochloride. It was the first alkaloid extracted from opium, and is the principal alkaloid in Indian opium. The amount in opium is from about 1 to 9 per cent., and it is nearly all uncombined, so that when opium is extracted with water nearly all the narcotine remains in the residue. This residue is extracted with dilute hydrochloric acid, the solution precipitated with sodium acetate, and the precipitate extracted with boiling alcohol; the alkaloid crystallises out on cooling. The above formula for narcotine is based on the following re-



Narcotine.

actions of the alkaloid and of its derivatives. Narcotine is a tertiary base because it combines with methyl iodide. It contains three methoxy-groups, because one molecular proportion of the alkaloid on treatment with hydriodic acid yields three molecular proportions of methyl iodide. Further: (1) it is hydrolysed by dilute sulphuric acid, giving opianic acid and hydrocotarnine. But these two do not yield narcotine when made to unite by warming with concentrated hydrochloric acid: an isomeric compound isonarcotine is the product. (2) It is reduced by zinc and dilute sulphuric acid to meconine and hydrocotarnine. (3) It is oxidised by manganese dioxide and sulphuric acid, or by nitric acid to opianic acid and cotarnine. (4) Meconine and hydrocotarnine are respectively reduction products of opianic acid and cotarnine. The constitution of meconine and of opianic acid is known. Cotarnine is an aldehyde; it is also a secondary base uniting with methyl iodide to form cotarninemethinemethyl iodide. This last compound is resolved by caustic soda into trimethylamine and cotarnone, and the latter on oxidation yields cotarnic acid. Cotarnine itself, on oxidation, yields cotarnic acid, and another acid of known constitution—the methyl betaine of cinchomeronic acid (apophyllenic acid). The constitution of cotarnic acid is deduced from the facts that it forms an anhydride, and yields on heating with hydrochloric acid the methylmethylene ether of gallic acid, and with hydriodic acid gallic acid itself. Thus we have:



Narrow (*Typog.*) The name applied to furniture (*q.v.*) three picas in width.

Narrow Gauge (*Civil Eng.*) A term now commonly applied in England to any railway track of gauge less than the standard gauge of 4 ft. 8½ in. A 3 ft. gauge is the commonest narrow gauge in England. It was formerly used to distinguish the present standard gauge from the wide gauge (*q.v.*), which is now obsolete.

Narthex (*Architect.*) An inner porch in Early Christian churches, used for the reception of penitents and the repetition of catechisms. It is separated from the nave by means of a screen. *See* BASILICA, NAVE.

Narwhal (*Zool.*) A cetaceous mammal (*Monodon monoceros*) belonging to the Dolphin tribe, frequenting Arctic seas. Its curious twisted tusk, often measuring eight feet in length, yields a very valuable ivory. The oil also is used in commerce.

Nasturtium (*Botany*). The watercress (*Nasturtium officinale*) is a member of the Dicotyledon order *Cruciferæ*. The garden nasturtium is a *Tropæolum* belonging to the *Tropæolaceæ*.

National Gallery (London). The present building on the north side of Trafalgar Square, erected from designs by Mr. Wilkins, was opened in 1838. The Gallery was founded in 1824 by the purchase of Mr. J. J. Angerstein's collection, numbering thirty-eight pictures, which were exhibited in Pall Mall. The Gallery contains most important examples of the English school, including masterpieces by Reynolds, Gainsborough, Landseer, Hogarth, Turner, Constable, Wilkie, Romney, Etty, Herring, Callcott, Mulready, Maclise, as well as many of the finest examples of Raphael, Titian, Corregio, Vandyck, Rembrandt, Rubens, Teniers, Cuyp, Murillo, Velasquez, Claude, and others. Admission to the public free on Mondays, Tuesdays, Wednesdays, and Saturdays; a charge of sixpence is made on Thursdays and Fridays (students' days).

National Gallery of British Art (Tate Gallery). This gallery, erected by the generosity of Sir Henry Tate, Bart., is situate at Millbank, S.W., facing the Thames. Many of the works of British artists have been transferred to this building from the National Gallery. Students' days, Tuesdays and Wednesdays. A charge of sixpence is made for admission on these days; on other weekdays admission is free.

National Portrait Gallery (London). This gallery is situate in St. Martin's Place (at the rear of the National Gallery). It was built by the generosity of Mr. W. H. Alexander, and was opened to the public in 1896. Previously the portraits were at South Kensington. The collection numbers about 1,400. Admission as to National Gallery.

Native. The term applied to metals which are found in the earth in the condition of elements. *See* METALLURGY *and* MINING.

Natrolite (*Min.*) A hydrous sodium aluminium silicate, $Na_2O \cdot Al_2O_3 \cdot 3SiO_2 \cdot 2H_2O$. Orthorhombic. One of the zeolites. It occurs in slender crystals, usually colourless, sometimes yellowish; also massive and radiating. It fuses in the candle flame. Also known as mesotype. From cavities in basic volcanic rocks in Scotland, Ireland, the United States, etc.

Natron (*Min.*) Sodium carbonate, $Na_2CO_3 \cdot 10H_2O$ Soda = 18·8, carbon dioxide = 26·7, water = 54·5 per cent. Monosymmetric, usually as an incrustration. It effervesces with acids, and effloresces on exposure. It occurs in association with other carbonates of sodium in Egypt, Hungary, and Mexico.

Natural (*Music*). Marked by a ♮. It has the power of restoring a note to its original position after being made sharp or flat. Naturals always fall on the white keys of the pianoforte, hence the scale of C is sometimes spoken of as the natural scale. When a natural occurs with a sharp or flat, as ♮♯, or ♮♭, it restores respectively a double sharp to a sharp, or a double flat to a flat.

—— *or* **Naperian Logarithms.** *See* LOGARITHMS.

Natural Draught (*Eng.*) Draught or air supply produced by the uprush of heated gases in flues and chimneys. *See also* FORCED DRAUGHT.

Natural Gas. Gaseous compounds of carbon and hydrogen which are given forth from the earth under various geographical conditions. They include the gaseous exhalations from swamps, the various gases given off by active or by dormant volcanoes, and the gaseous compounds arising from bore holes that have penetrated to the underground reservoirs where petroleum is found. The gas is principally Methane, but is accompanied by Hydrogen, Ethane, Propane, and Butane.

Natural Magnet. *See* MAGNET.

Natural Period (*Phys.*) The time occupied by some cycle of operations, movements, etc., when the body (or system of bodies) under consideration is left to itself.

Natural Scale (*Surveying*). A scale so named as to indicate the ratio a distance, as represented on a map, bears to the actual distance; *e.g.* one inch to a mile is represented by the natural scale $\frac{1}{63360}$.

Natural Waters (*Chem.*) These are rain, river, spring, and sea water. *See* WATER.

Naumachia (*Archæol.*) A large building in the form of an amphitheatre, used by the Romans for giving representations of sea fights.

Naumann's Notation (*Min.*) One of the systems of expressing the relation of a crystal form to the axis. In it the components of the symbol express the relations of the intercepts of the crystal form on the three axes, the unit length of the axis being designated by O in the cubic system and P in the other systems, while ∞ is used when the intercept is infinity, *i.e.* when the form is parallel to that particular axis.

Naut *or* **Knot.** *See* NAUTICAL MILE.

Nautical Almanack (*Astron., Navigation*). An elaborate series of data showing the motions and positions of the celestial bodies. It is compiled at the Nautical Almanack Office in London, for four years in advance, and furnishes data which are absolutely indispensable in navigation and exploration, and of the utmost importance to all astronomical observers. It is perhaps the finest example in existence of the utility of what are apparently the most abstruse and theoretical observations and calculations.

Nautical Mile. A minute of arc of the Meridian; sometimes called a knot, though the latter is, correctly speaking, the rate of one nautical mile per hour. A nautical mile is 6,087 ft., or 1·152 miles. *See also* WEIGHTS AND MEASURES.

Naval Crown (*Her.*) A circlet on which is arranged alternately four sterns and four masts with sail.

Nave. The central part of a wheel; also called HUB and BOSS.

—— (*Architect.*) The part of a church situate between the aisles and west of the chancel. The term nave is derived from the Greek word *Naos*. *See* CELL, AISLE, *and* CHANCEL.

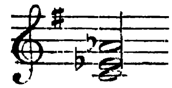
Navier's Formula (*Eng., etc.*) *See* GORDON'S FORMULA.

Nb (*Chem.*) The symbol for NIOBIUM (*q.v.*)

Ne (*Chem.*) The symbol for NEON (*q.v.*)

Neapolitan Sixth (*Music*). The major common chord of the minor second of the key in its first inversion—a chord on the subdominant with the

minor 3rd and minor 6th added. In the key of G the Neapolitan 6th is



Neap Tides (*Astron.*) *See* TIDES *and* LAGGING.

Neat (*Plastering*). Cement or plaster without the addition of sand, *i.e.* a mixture of cement or plaster with water only.

Neat's Foot Oil. *See* WASTE PRODUCTS.

Neat Soap (*Soap Manufac.*) *See* FITTING.

Nebeculæ (*Astron.*) *See* MAGELLANIC CLOUDS.

Nebris (*Art*). A fawn's skin, the covering of Bacchus, Bacchantes, and fauns.

Nebula (*Astron.*) A luminous cloud seen in the heavens on a dark night, which no telescopic power can resolve into stars. The form is both regular and irregular. That in Orion is the most brilliant and easy to see.

Nebular Hypothesis (*Astron.*) A hypothesis first worked out in mathematical detail by Laplace. The basis of it is that at some time in the past the matter which is now gathered into the form of the sun and planets was once a large nebula in an incandescent state. This subsequent cooling and rotating mass contracted and left behind masses which form the planets.

Nebule (*Architect.*) An enriched moulding used in Norman work. The lower edge of the moulding is an undulating line, in the hollows of which spheroidal forms are worked.

Nebuly *or* **Nebulée** (*Her.*) A partition line. Similar to dovetail joint, only instead of being angular it bends in curves.

Neck (*Architect.*) That part of a capital immediately above its lowest mouldings, usually a continuation of the shaft; *e.g.* that part of a Roman Doric capital between the astragal and the annulets. *See* COLUMN.

—— (*Eng.*) A general name for a narrow portion of some object; in particular, the JOURNAL (*q.v.*) of a shaft.

Necklace. An ornament worn round the neck; probably the most universal and the oldest form of personal adornment.

Necks, Volcanic (*Geol.*) A general term for the materials which have finally occupied the pipe or chimney of a volcano between the crater and the focus. In many cases the vent is occupied by fragmentary material or agglomerate, which has been ejected from the volcano during an explosive eruption, and which has subsequently fallen back into the vent and finally choked it up. In other cases the vent has been filled with what was originally fluid rock, which has consolidated there and been left as a plug; or there may exist a combination of these two. Necks commonly give rise to conspicuous scenic features.

Necropolis. A large cemetery; in ancient times the burial places were frequently subterranean. *See* CATACOMBS.

Needle (*Carp.*) In shoring, the needle is the horizontal timber going through the wall and resting on the top of dead shores or the head of raking shores. *See* SHORING.

Needle (*Elect.*) *See* MAGNETIC NEEDLE.

—— (*Mining*). A rod used in making a small hole for firing a blasting charge.

——, **Astatic** (*Elect.*) *See* ASTATIC NEEDLES.

——, **Dipping** (*Elect.*) A magnetic needle turning about a horizontal axis; used in measuring the DIP (*q.v.*)

Needle Lubricator (*Eng.*) An oil vessel with a vertical passage or tube leading from the lowest part of the oil space to the point where lubrication is required. A thin rod loosely fitting this passage prevents a too rapid flow of oil, but its vibration causes a small regular stream to run down into the bearing.

Needle Machine (*Lace Manufac.*) That form of Swiss embroidery machine, also known as the hand machine, wherein small needles with an eye in the middle, threaded with a suitable length of silk or thread, are mechanically passed back and forth through the fabric to be embroidered, with the same results as in hand work. It is a much slower process (about six stitches a minute) than shuttle embroidery, but the results attained justify the extra labour.

Needle Valve (*Eng.*) A valve consisting of a pointed rod of metal; the point just fits into a suitably shaped hole, which it opens or closes by its motion. Needle valves are commonly used in SPRAY CARBURETTERS (*q.v.*)

Negative (*Photo.*) A photographic image or picture in which the lightest portions of the object are represented by the darkest portions of the image, and *vice versâ*. A negative is formed by the action of the light on a sensitive film, which is supported on a plate of glass or a sheet of paper or celluloid.

—— (*Textile Manufac.*) A term applied to any shedding or taking up motion requiring the assistance of springs or weights. Sometimes termed non-positive. Also applied to different working parts of spinning machinery.

Negative Brush (*Elect.*) The brush of a dynamo or motor, which is connected to the negative terminal.

Negative Charge (*Elect.*) A charge of electricity of the kind produced on a rod of resin by rubbing it with flannel.

Negative Crystal (*Phys.*) A Uniaxal Crystal (*q.v.*) in which the velocity of the Extraordinary Ray is in general greater than that of the Ordinary Ray. *See also* DOUBLE REFRACTION.

Negative Plate of a Cell (*Elect.*) In a primary cell, the zinc plate (or corresponding element); in a storage cell or accumulator, the plate which is connected to the negative terminal of the charging dynamo.

Negative Stress (*Eng., etc.*) A TENSION or TENSILE STRESS.

Negur (*Soap Manufac.*) The dirty aqueous layer which settles in the soap pan in the manufacture of fitted soaps (*q.v.*) Also spelled negre, nigre, and nigger. *See* FITTING.

Neodymium (*Chem.*) *See* DIDYMIUM.

Neon (*Chem.*), Ne. Atomic weight, 20. A gas occurring in air (1 to 2 parts in 100,000); has no reactions; the ratio of the two specific heats is 1:66, so that it has a monatomic molecule, and is therefore an element. Has a characteristic and complex spectrum—many lines in the red, three in the green, and a number of blue lines. Density, 9·97. Critical temperature below −205°. To obtain it the uncondensed gases from an air liquefier, consisting of helium, neon, nitrogen, argon, etc., are liquefied and air blown through the liquid. The first portions of gas which come away are collected separately, and the oxygen and nitrogen removed respectively by red-hot copper and heated magnesium. The remaining gas is liquefied, and on distillation helium and neon pass over, and these can be separated by fractional distillation at the temperature of boiling hydrogen: at this temperature helium is gaseous, while neon is liquid or possibly solid.

Nep (*Textile Manufac.*) Small cluster of fibres in the wool staple. Difficult to open or separate. It is such fibres that form NOIL (*q.v.*) in the combing process. *See also* NEPS.

Nepheline (*Min.*) A silicate of aluminium, sodium, and potassium, $3Na_2O.K_2O.4Al_2O_3.9SiO_2$. Silica = 44·2, alumina = 33·7, soda = 16·9, potash = 5·2 per cent. Hexagonal; usually in short prisms. It occurs in several kinds of eruptive rocks. One of the best known localities is Monte Somma.

Nephelium (*Botany*). A genus of the order *Sapindaceæ*, native to Malayasia. It is important on account of its fruits, the Rambutan, Longan, and Litchi.

Nephrite (*Min.*) A synonym for jade (*q.v.*)

Neps (*Cotton Manufac.*) Damaged or broken fibres which have escaped the action of the carder and appear as specks on the doffer web.

Neptune, Planet (*Astron.*) Distance from sun, 2,791,000,000 miles; mean diameter, 34,800 miles; periodic time, nearly 165 years. Possesses one satellite. This planet was discovered by Le Verrier and Adams from purely theoretical calculations, which predicted its existence on account of certain perturbations (*q.v.*) which were produced in the motion of Uranus by some unknown body.

Nernst Lamp. *See* ELECTRIC LIGHTING.

Neroli, Oil of (*Botany*). An oil obtained by distillation of the flowers of *Citrus aurantium*, var. *Bigaradia*. It is extensively used in perfumery.

Nervures (*Architect.*) The ribs bounding the sides of a vaulted compartment.

Nessler's Reagent (*Chem.*) A solution of mercuric chloride (17 grams in 300 cc. water) is added to a solution of potassium iodide (35 grams in 100 cc. water) till a permanent precipitate is obtained; then a 20 per cent. solution of caustic soda is added to make up to a litre. A little more of the mercuric chloride is now added to cause a slight precipitate. The clear liquid is Nessler's reagent. It is used as a test for ammonia: delicacy, about 1 part ammonia in 25,000,000 parts water. For action *see* MERCURY COMPOUNDS.

Nest (*Glass Manufac.*) A cushion upon which sheets of glass are placed for splitting with the diamond.

Nest Gearing (*Eng.*) A set of enclosed gear wheels.

Neurine (*Chem.*) Trimethylvinylammonium hydroxide, $(CH_3)_3N{<}^{CH=CH_2}_{OH}$. A syrupy liquid; very soluble in water; powerful alkali; very poisonous. Forms salts with acids. The picrate is sparingly soluble in cold water, easily soluble in hot water, and melts at 263°. Neurine gives precipitates with the alkaloid reagents. It is classed among the ptomaines, and is found in putrid human, horse, and ox flesh, and in the urine in Addison's disease. It can be prepared from choline (*q.v.*) by acting upon it with hydriodic acid, which converts it into the iodide $(CH_3)_3N{<}^{CH_2.CH_2I}_{I}$. The latter with moist silver oxide gives neurine. When ethylene dibromide is acted on by trimethylamine the bromide corresponding to the above iodide is produced, and this also gives neurine by heating with moist silver oxide.

Neutral (*Paint.*) A term applied to colours without predominant tone, *e.g.* in watercolour painting certain grey colours are so called.

Neutral Axis (*Eng., etc.*) The intersection of the cross section of a beam and the neutral layer. *See* BEAM. The neutral layer itself is sometimes incorrectly called the neutral axis.

Neutral Conductor, Feeder, *or* **Wire** (*Elect. Eng.*) The central or balancing wire of a THREE WIRE SYSTEM (*q.v.*)

Neutral Equilibrium (*Phys., etc.*) A body is in neutral equilibrium if on receiving a small displacement there is no tendency for this displacement, either to increase as in UNSTABLE EQUILIBRIUM (*q.v.*), or to decrease as in STABLE EQUILIBRIUM (*q.v.*) *See* EQUILIBRIUM NEUTRAL.

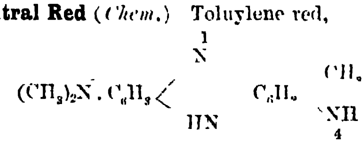
Neutralisation (*Chem.*) The process of adding a base to an acid or an acid to a base till the product has the reaction of neither. A base turns red litmus blue, while an acid turns blue litmus red; at the neutral point the product has no action on either red or blue litmus.

Neutral Layer (*Eng., etc.*) The part of a loaded beam in which there is no stress. *See also* BEAM.

Neutral Line (*Eng.*) The NEUTRAL AXIS (*q.v.*)

Neutral Points of a Dynamo (*Elect. Eng.*) Two points on the commutator (at the extremities of a diameter) at which the brushes must rest, in order that the current may be led away without sparking at the brushes. *See also* DYNAMO.

Neutral Red (*Chem.*) Toluylene red,



Orange red needles which contain four molecules water of crystallisation: this water is expelled at 150°, leaving the blood red anhydrous base. Soluble in alcohol and ether with strong fluorescence. Its hydrochloride is a red dye; it dyes cotton mordanted with tannin. It is prepared by oxidising a mixture of dimethylparaphenylenediamine and metatoluylenediamine. Neutral red is used in bacteriology. The B. coli communis a common intestinal bacterium —has the power of reducing a solution of neutral

red, thus changing its colour to a yellow. If a water coloured by this dye is changed to a yellow colour it is *one* indication of the presence of the above organism, and therefore of the presence of sewage.

Neutral Temperature (*Phys.*) *See* THERMO-ELECTRIC JUNCTION.

Neutral Tint (*Paint.*) An artist's watercolour, made by mixing Indian ink and Chinese blue with a little madder. The result is a pleasing grey having a slightly violet hue.

New Blue (*Dec.*) A permanent blue of great purity, permanent in oil and water and valuable for decorators' purposes. It is a variety of artificial ultramarine blue, and ranges in colour from a greenish to a violet hue.

Newel (*Join.*) A column supporting a handrail, *e.g.* the column at the commencement of the balusters on a staircase.

Newel Steps (*Join., etc.*) Winding steps supported by a newel formed on the narrow ends of the steps.

New Moon (*Astron.*) The moon in such a position that its longitude is the same as that of the sun. When "new" the moon is invisible. During total solar eclipses the moon is "new."

New Star (*Astron.*) When in any particular part of the heavens a star suddenly appears where no star had ever been observed before, a "new star" is said to have made its appearance.

Newtonian Constant of Gravitation (*Phys.*) *See* GRAVITATION.

Newtonian Telescope (*Astron.*) The form of reflecting telescope mostly used, in which the light from the object observed, after being reflected from the surface of a parabolic mirror, falls on a small plane mirror, placed in the optical axis of the first, at an angle of 45°, and is viewed from the side of the telescope tube.

Newton's Law of Cooling. Under certain conditions, the rate at which a hot body cools (*i.e.* the amount of heat emitted per unit time) is proportional to the difference of temperature between the hot body and the surrounding medium.

Newton's Rings. A series of coloured rings produced when two transparent curved surfaces, of different radii, are placed in contact, *e.g.* when a convex lens of large radius is pressed against a plane sheet of glass. The rings surround the point of contact, and are formed both by reflected and by transmitted light.

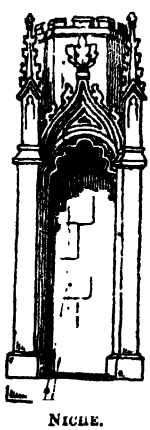
New Zealand Flax (*Botany*). A strong useful fibre obtained from the veins of the leaves of the plant *Phormium tenax* (order, *Liliaceæ*). Used in the manufacture of baskets and ropes.

Ni (*Chem.*) The symbol for NICKEL (*q.v.*)

Nib (*Build.*) A projection on the back of a tile, for fixing to the battens.

Niccolite (*Min.*) A synonym for KUPFERNICKEL (*q.v.*)

Niche (*Architect.*) A recess in a wall, generally intended for the reception of a statue. The plan of the recess is either rectangular, segmental, or semicircular, the last being the most common form.



NICHE.

Nicholson's Hydrometer. *See* HYDROMETER, NICHOLSON'S.

Nicholson's Machine (*Typog.*) A printing machine patented by William Nicholson, 1790. The first machine built with a cylindrical impression motion and mechanical inking contrivance.

Nichol's Prism (*Light*). *See* POLARISATION.

Nick (*Typog.*) A groove in the front of the shank of a type. It makes a distinction between different sorts and sizes, and enables the compositor to lift it in proper position.

Nickel (Ni). Atomic weight, 58·7. A hard white metal capable of a high polish; melts at a rather lower temperature than iron; specific gravity 8·9; it is magnetic; in its chemical properties it resembles iron, but it is less easily oxidised, hence the use of nickel plating. Red-hot nickel only decomposes steam slowly, forming the monoxide. Hydrochloric and sulphuric acids slowly dissolve it. Concentrated nitric acid causes it to assume the passive state just as it does iron (*q.v.*); dilute nitric acid readily dissolves it. Finely divided nickel combines with carbon monoxide between 30° and 80° to form nickel carbonyl, $Ni(CO)_4$. It occurs as kupfernickel, NiAs; pyrrhotite, a magnetic pyrites in which iron is replaced by nickel to the extent of 5 per cent. of the latter or more; nickel glance, NiAsS; pentlandite, (NiFe)S; garnierite, $2\left\{(Ni.Mg)_5Si_4O_{13}\right\}3H_2O$. It is found with iron in meteorites. Many methods are in use for its extraction, owing to the great variety of its ores. The Mond process is now worked on a large scale in South Wales. The Canadian ores (chiefly pyrrhotite) are roasted, then melted with coke in a blast furnace; the product is then oxidised in a Bessemer converter. This product, containing about 40 per cent of nickel, is brought to South Wales and treated by the Mond process, which is, in brief: (1) roasting of the "matt"; (*b*) reduction by water gas below 400°; (*c*) treatment in a special vessel by carbon monoxide at 80° to form nickel carbonyl; (*d*) decomposition of the nickel carbonyl at 180° in special tubes where the nickel is deposited, and the carbon monoxide is used over again. The carbon monoxide required is made from products of combustion by purifying the smoke and passing it over heated coke. The nickel is melted and cast into the form required. In America, where most nickel is extracted, an electrolytic process is employed, the ore being first submitted to a preliminary treatment like that for the Mond process. Nickel is much used for electroplating (*q.v.*); in making coins, both alloyed with other metals and pure (0·98 fine); in making German silver (*q.v.*) and nickel steel. *See* IRON. Finely divided nickel acts as a catalytic agent in bringing about the union of hydrogen and certain unsaturated compounds, especially hydrocarbons; *e.g.* vapour of benzene and hydrogen passed over it at 180° to 200° give hexahydrobenzene; homologues of benzene behave similarly. *See also* METHANE.

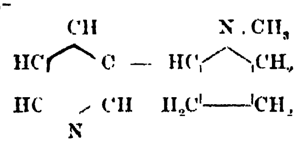
Nickel Compounds. NICKEL OXIDE, NiO, is a green powder; melts in the electric furnace and forms green crystals on solidification. Reduced to the metal on heating in hydrogen, or in carbon monoxide,

or with carbon (at 550°), carbon dioxide being formed in this case. It behaves as a basic oxide. It is obtained by heating the hydroxide or nitrate. Nickel sulphide, NiS, is a yellow solid in the natural state (millerite) or when obtained by heating nickel and sulphur together; a black powder when obtained by adding ammonium sulphide to a solution of a nickel salt; it is insoluble in dilute hydrochloric acid, but it dissolves in ammonium sulphide—this is a useful distinction from cobalt. NICKEL SULPHATE, $NiSO_4$, is a yellow solid when anhydrous; but the ordinary crystallised salt, $NiSO_4 6H_2O$, is green. Nickel sulphate is very soluble in water (37·4 $NiSO_4$ in 100 at 16°); the crystallised salt loses $5H_2O$ at 100°, and becomes anhydrous above 280°. It is obtained by dissolving the metal, its hydroxide or carbonate, in dilute sulphuric acid. It combines with ammonium sulphate to form the double salt $(NH_4)_2SO_4NiSO_4 6_2HO$. This salt is used in nickel plating; also, by electrolysis of its solution, made alkaline with ammonia, chemically pure nickel can be obtained. NICKEL CYANIDE, $Ni(CN)_2$, is obtained as a green precipitate on adding potassium cyanide solution to a solution of a nickel salt; it dissolves in excess, forming $K_2Ni(CN)_4$, but no salt corresponding to the cobalticyanides. Hypochlorites or hypobromites give black hydrated nickelic oxide with this double salt—distinction from the cobalticyanides. NICKELIC OXIDE, Ni_2O_3, is a black powder obtained by gently heating the nitrate; its hydrate, $Ni_2O_3 3H_2O$, is obtained by adding a hypochlorite or hypobromite solution to any solution of a nickel salt. Its behaviour is that of a peroxide. *See* OXIDES. NICKEL CARBONYL, $Ni(CO)_4$, is a colourless liquid; boils at 40°, and has a normal vapour density—the vapour explodes at 60°. In an inert gas it can be heated without explosion, but it dissociates: in nitrogen dissociation is complete at 155°. It is soluble in alcohol, benzene, chloroform. It burns in air with a white flame. Its vapour is poisonous and the action is characteristic—and not carbon monoxide poisoning. To prepare it nickel oxide is reduced in hydrogen at about 400°; the reduced nickel is allowed to cool to from 30° to 80°, and carbon monoxide is passed over it, and the escaping gas cooled by ice and salt when the nickel carbonyl condenses.

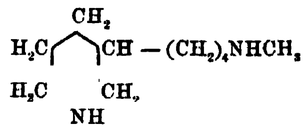
Nickel Pyrites (*Min.*) A synonym for Millerite (*q.v.*)

Nicker (*Carp., etc.*) The cutting lip of certain forms of bits used in boring wood.

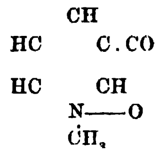
Nicotine-



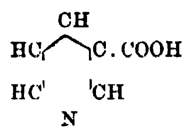
(β-pyridine-N-methyl-α-pyrrolidine). A colourless oily liquid; boils at 247°; has a mouse-like smell when pure, but smells like tobacco when impure; extremely poisonous; optically active, being lævorotatory; soluble in water and the usual organic solvents; turns brown on exposure to air. It is basic, and forms a number of salts. Nicotine occurs in tobacco leaves to a very variable amount—from 0·5 to 8 per cent.; tobacco smoke also contains nicotine. It is obtained from tobacco leaves by soaking them in acidulated water, concentrating the extract, adding quicklime, and distilling; the crude alkaline distillate is neutralised with oxalic acid and evaporated; on adding concentrated caustic potash the nicotine separates, and is extracted with ether; on distilling off the ether finally in a stream of hydrogen the pure base can be distilled over. The following reactions of nicotine are important: it can add two, six, or eight atoms of hydrogen; in the last case the pyrrolidine ring is probably opened—



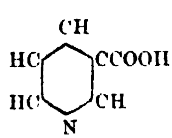
It forms two isomeric iodomethylates: (1) by treating its hydriodide in boiling alcoholic solution with methyl iodide and neutralising with caustic soda—this iodomethylate yields a hydroxide with moist silver oxide, which on oxidation with potassium permanganate gives trigonelline—



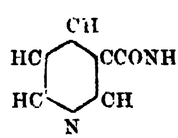
showing that the methyl iodide has added itself to the pyridine nitrogen. (2) By mixing methyl alcohol solutions of nicotine and methyl iodide, when the methyl iodide adds itself to the pyrrolidine nitrogen: thus nicotine is a ditertiary base. When an aqueous solution of nicotine is boiled with silver oxide it gives nicotyrine; on oxidation nicotine yields nicotinic acid, which has the formula—



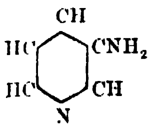
Nicotine has been synthesised as follows: From nicotinic acid (*see* PYRIDINE) the amide can be prepared by treating its ethyl ester with ammonia. Sodium hypobromite converts the amide into β-aminopyridine. The latter, when heated with mucic acid, yields β-pyridyl-N-pyrrole, which undergoes intramolecular rearrangement on passing it through a tube heated to low redness to β-pyridyl-α-pyrrole. The potassium compound of β-pyridyl-α-pyrrole, on treatment with methyl iodide, yields the iodomethylate of nicotyrine, which is identical with the iodomethylate of nicotyrine obtained from natural nicotine. From nicotyrine, by action of a solution of iodine in caustic soda, iodonicotyrine is obtained, which on reduction with zinc and hydrochloric acid, gives dihydronicotyrine, a liquid strongly resembling nicotine itself. On brominating the last product and reducing the dibromide with tin and hydrochloric acid, inactive nicotine is obtained, which can be resolved into active nicotine by fractional crystallisation of its tartrate—



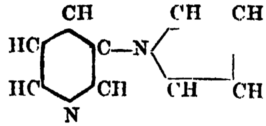
Nicotinic Acid.



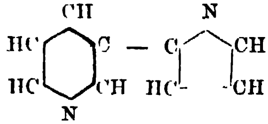
Nicotinic Acid Amide.



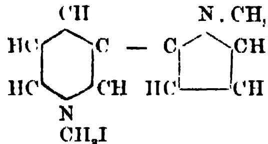
β-aminopyridine.



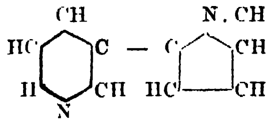
β-pyridyl-N-pyrrole.



β-pyridyl-α-pyrrole.



Nicotyrine Iodomethylate.



Nicotyrine.

The only step which has not been taken is the conversion of nicotyrine iodomethylate into nicotyrine.

Niello. A process of ornamenting metal plates by cutting a design upon the surface, the incisions being then filled in with a black or coloured composition. The best examples are those by Italian artists of the fifteenth century.

Niger Seed Oil. Made from Niger seed, the product of an Abyssinian plant, either by hot or cold pressure, after grinding. The colour is similar to olive oil, the specific gravity ·924. It has poor drying qualities, and is principally used in India for food.

Nimbus (*Art*). The halo or disc surrounding the head in representations of saints. *See* AUREOLA.

Nimbus Clouds (*Meteorol.*) A class of cloud. It is the cloud of continued rain or snow. Has ragged edges. *See* CLOUDS.

Niobium (*Chem.*) Nb. Atomic weight, 94. A rare metal belonging to the nitrogen group in the periodic system (*q.v.*) It occurs in columbite (the Americans call the metal columbium), yttrotantalite, euxenite.

Nippers (*Eng., etc.*) Pliers, either for holding or for cutting metal, etc.

Nipple (*Gas Fitting, etc.*) A piece of pipe with a male thread cut the whole of its length.

Nipples (*Cycles*). Small tubular nuts used to fix the heads of spokes to the rim of the machine.

Nitrates. Salts or esters of nitric acid, derived from the acid by replacement of its hydrogen by a metal or alcohol radical.

HNO_3 Nitric Acid.	KNO_3 Potassium Nitrate.	$C_2H_5 . NO_3$ Ethyl Nitrate.
HNO_3 HNO_3	$Pb\langle^{NO_3}_{NO_3}$ Lead Nitrate.	$Cu\langle^{NO_3}_{NO_3}$ Copper Nitrate.
HNO_3 HNO_3 HNO_3	$Bi(NO_3)_3$ Bismuth Nitrate.	$CH_2 . NO_3 — CH . NO_3 — CH_2 . NO_3$ Glyceryl Trinitrate (Nitroglycerine).

The nitrates are prepared by dissolving the metal, its oxide, or its carbonate, whichever is most convenient, in nitric acid, and crystallising the solution; or in the case of the esters the alcohol is treated with nitric acid, or, as in the case of nitroglycerine, with a mixture of nitric and sulphuric acids. Some nitrates occur naturally, *e.g.* sodium and potassium nitrates. The metallic nitrates are soluble in water, except in a few cases, where the nitrate is decomposed by water, forming basic nitrates, which are insoluble in water. The common metals which form basic nitrates are bismuth and mercury. The nitrates of these metals easily dissolve in water acidified with nitric acid. The effect of heating nitrates is as follows: Ammonium nitrate gives nitrous oxide and water; potassium and sodium nitrates at low redness give the corresponding nitrites, but at higher temperatures a mixture of oxides; other nitrates give oxygen, nitrogen peroxide, and a metallic oxide, or, if the oxide itself is easily decomposed by heat, the metal and oxygen. Most nitrates are insoluble in concentrated nitric acid. Nascent hydrogen reduces their solutions to nitrite, then to ammonia. The nitrates of alcohol radicals (nitric acid esters) are liquids unless the alcohol has a high molecular weight, when they are solid, and explosive on moderate heating or on detonation; they are hydrolysed like other esters. Ethyl nitrate, on reduction with tin and hydrochloric acid, yields hydroxylamine. For particular nitrates *see under* the various metals and alcohol radicals.

Nitrates in Water. *See* SANITATION.

Nitre (*Chem.*) A common name for potassium nitrate. *See* POTASSIUM COMPOUNDS.

—— (*Min.*) Potassium nitrate, KNO_3. Potash = 46·6, nitric acid = 53·4 per cent. Orthorhombic in prismatic crystals, also as an encrustation. Soluble in water. The chief supply comes from the soils of certain districts in India, Egypt, Persia, etc.

Nitric Acid (*Chem.*) Aqua fortis, HNO_3. A colourless liquid. Boils with decomposition at 86°, $2HNO_3 = H_2O + 2NO_2 + O$, hence the acid changes composition on distillation, becoming weaker, till at 760 mm. the boiling point has risen to 120°, when an acid of 68 per cent., HNO_3 (sp. gr. 1·414 at 15°), distils unchanged. Nitric acid eagerly absorbs water from the air, and as the strong acid is volatile it fumes in air, owing to the water vapour present in it. The strongest nitric acid, which can be prepared in the usual way (*see* below), corresponds to 99·975 per per cent., HNO_3; but it seems very doubtful if strong nitric acid has the composition HNO_3 at all. The kind of evidence on which this statement is based is the following. The electrical conductivity of nitric acid increases from a 1·3 to a 30 per cent. solution, HNO_3, then diminishes slowly to 76 per cent., then rapidly to 96·12 per cent., whence it increases again; also from 96·12 per cent. upwards the conductivity diminishes with increase of temperature like that of a metal. Similar irregularities show themselves in the case of other physical constants

such as refractive index, absorption of ultra-violet light, magnetic rotation, contraction on dilution with water. It is inferred that such changes can only be caused by changes in chemical composition. Professor Hartley thinks the strongest acid may have the formula $H_2N_2O_6$; while an acid = 89·6 per cent., HNO_3, may be a mixture of $H_2N_2O_6$ and H_3NO_4. The strongest acid obtainable differs considerably in chemical behaviour from ordinary or from fuming nitric acid, in that it has no action at the ordinary temperature on many metals, such as copper, silver, mercury, magnesium, which are readily acted on by ordinary nitric acid, and tin is not acted on even when boiled with it. Calcium carbonate is also unattacked by the boiling acid; but it readily oxidises sulphur, and nitrates organic compounds. Ordinary nitric acid has the following chemical behaviour: (*a*) It acts as a strong monobasic acid. (*b*) It oxidises many non-metals, *e.g.* carbon to carbon dioxide, iodine to iodic acid, HIO_3, phosphorus to phosphoric acid, arsenic to arsenic acid, sulphur to sulphuric acid. (*c*) It oxidises various "-ous" salts to "ic" salts, *e.g.*

$$6FeSO_4 + 8HNO_3 = 2Fe_2(SO_4)_3 + Fe_2(NO_3)_6 + 2NO + 4H_2O.$$

(*d*) Its action on sulphides depends on the strength of the acid. A diluted acid will give a nitrate and liberate sulphur (sulphuretted hydrogen may be formed and oxidised to water and sulphur), while the strong acid will oxidise the sulphide to sulphate. (*e*) Its action on metals seems to be dependent on the presence of nitrous acid; for when the acid is freed from nitrous acid, its action on metals is extremely slow, and its rate of action increases with increase in amount of nitrous acid. The nitrous acid seems to arise in the first place from electrolytic action set up between the metal and traces of impurities contained in it. The nitrous acid forms a nitrite of the metal, and the nitrite is decomposed by the nitric acid. In the case of copper the reactions are:

$$Cu + 4HNO_2 = Cu(NO_2)_2 + 2H_2O + 2NO$$
$$Cu(NO_2)_2 + 2HNO_3 = Cu(NO_3)_2 + 2HNO_2$$
$$2NO + H_2O + HNO_3 = 3HNO_2$$

When the nitrous acid reaches a certain concentration the third reaction becomes reversible, and at this stage nitric oxide escapes. But other reactions occur too, owing to decomposition of the acids in other ways; thus with copper and nitric acid of sp. gr. 1·2, besides 90 per cent. of nitric oxide, 10 per cent. of nitrogen peroxide is evolved, while with acid of sp. gr. 1·3 and over the only products are nitrogen trioxide and peroxide. Nitric acid acts on silver, bismuth, and mercury very much in the same way as on copper. With lead the reduction products are different—40 per cent. nitrous oxide, 50 per cent. nitric oxide, and 2·5 per cent. nitrogen peroxide. In general, when nitric acid acts on metals, a nitrate is produced and reduction products of the acid, which vary with the nature of the metal, concentration of acid, and temperature. Ammonia is among the reduction products when the dilute acid acts on tin and iron, and even hydrogen is evolved as such when the acid acts on magnesium. (*d*) On organic compounds it acts: (1) As an oxidising agent; *e.g.* cane sugar is oxidised to oxalic acid. (2) On fatty compounds containing hydroxyl groups to form nitrates. This action occurs in absence of nitrous acid and in presence, as usual, in case of ester formation, of a dehydrating agent; *e.g.* cane sugar gives an octonitrate with concentrated nitric and sulphuric acids. The preparation of nitro-glycerine and gun cotton are other examples of the formation of nitrates. *See also* ETHYL NITRATE. (3) To form nitro-compounds, *e.g.* Nitrobenzene (*q.v.*) Nitric acid is formed in the atmosphere during electric discharges. Nitrogen combines with oxygen to form nitric oxide, which then unites with a further quantity of oxygen to form the peroxide, and the latter in contact with water gives nitric acid, $3NO_2 + H_2O = 2HNO_3 + NO$. This change has been imitated on a manufacturing scale for the production of nitric acid. Ordinarily the acid is prepared by distilling potassium nitrate with sulphuric acid on the laboratory scale, or sodium nitrate in place of the potassium salt on a manufacturing scale. The distillate is always yellow on account of dissolved nitrogen peroxide, and it contains water and other impurities. To remove water it is mixed with concentrated sulphuric acid and redistilled; to remove nitrogen peroxide dry air is passed through the acid at a temperature not exceeding 35°C. The air used should be filtered through glass wool to remove dust. Such pure strong acid must be kept in the dark, as it is decomposed by light, the nitrogen peroxide again forming and turning the acid yellow. A very strong acid of sp. gr. 1·5 and rather over, and of a yellowish red colour, is much used in organic chemistry under the name of "fuming nitric acid" for making nitro compounds. This acid is produced by using acid and nitrate in the proportions required by the equation

$$2KNO_3 + H_2SO_4 = K_2SO_4 + 2HNO_3,$$

and working at a higher temperature when a part of the nitric acid decomposes, giving nitrogen peroxide, to which the acid owes its red tint. Ordinarily more sulphuric acid than this is used; or more sulphuric acid may be used and a little starch added, which gives with a part of the nitric acid large quantities of nitrogen peroxide. Nitric acid gives a rose colour with brucine and a deep blue colour with diphenylamine in strong sulphuric acid. Both these are delicate tests, but the latter is given by nitrites, chlorates, and other oxidising agents.

Nitric Anhydride (*Chem.*) *See* NITROGEN PENTOXIDE *under* NITROGEN OXIDES.

Nitric Oxide (*Chem.*) *See* NITROGEN OXIDES.

Nitrides (*Chem.*) Compounds formed by the union of two elements, one of which is nitrogen. The compounds of nitrogen with the commoner non-metals are not usually called nitrides; for example, the compounds of nitrogen and hydrogen have special names: NH_3 is called ammonia, N_2H_4 is called hydrazine, and the compound of nitrogen and carbon is called cyanogen, C_2N_2. The compounds of nitrogen and oxygen are called nitrogen oxides. For nitrides see under the name of the other element, *e.g.* under BORON COMPOUNDS, MAGNESIUM COMPOUNDS, etc.

Nitrification (*Chem.*) The bacteriological process by which ammonia, liberated from decaying nitrogenous organic matter or brought into soils by rain, is changed in the soils to nitrates. Two kinds of bacteria are concerned in the process, one kind oxidising the ammonia to a nitrite, and the other kind oxidising the nitrite to nitrate.

Nitriles (*Chem.*) Cyanides of organic radicals. Compounds of the formula $R^N.(CN)^N$, where R is hydrogen or a hydrocarbon residue, and N is a whole number. They are usually colourless liquids with an agreeable smell, and except the simplest members insoluble in water; *e.g.* formonitrile and acetonitrile are soluble in water, propionitrile only partly soluble in water. They are named in two ways: (*a*) from the acid formed on hydrolysis, *e.g.* acetonitrile, CH_3CN, which yields acetic acid on hydrolysis; (*b*) from the alcohol radical united to the cyanogen group, *e.g.* methyl cyanide, CH_3CN. Again, C_6H_5CN may be called benzonitrile or phenylcyanide. Nitriles can be obtained in many ways: (1) From potassium cyanide either by heating its alcoholic solution with an alkyl iodide or bromide at 100° or over, or by distilling it with an alkyl hydrogen sulphate. In both cases some of the isomeric isocyanide is formed, which may be removed by warming with dilute hydrochloric acid. The nitriles can be separated from their aqueous solutions, when they are soluble in water, by addition of calcium chloride. (2) By the action of phosphorus pentoxide on an acid amide, a reaction which goes in the case of acetamide without heating:

$$CH_3C\begin{matrix}\diagup O\\ \diagdown NH_2\end{matrix} = CH_3C\equiv N + H_2O$$

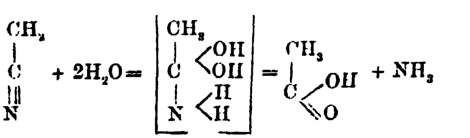
As the acid amides are themselves obtained by dehydration of ammonium salts, nitriles can be obtained directly from ammonium salts by acting on the latter with sufficient of the dehydrating agent. (3) By the action of acetic anhydride or acetyl chloride on an aldoxime; this is also a dehydrating action:

$$\underset{\text{Acetaldoxime.}}{CH_3.C\begin{matrix}\diagup H\\ \diagdown NOH\end{matrix}} + \underset{\text{Acetic Anhydride.}}{\begin{matrix}CH_3CO\\ CH_3CO\end{matrix}\!\!>\!O} = CH_3C\equiv N + 2CH_3COOH.$$

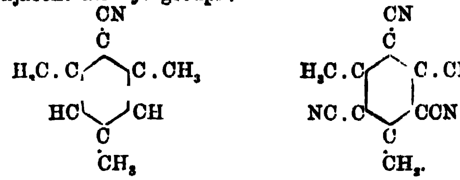
(4) Aromatic nitriles can also be obtained by the preceding methods, but are best obtained by one of the following: (*a*) From the diazo-compound by action of potassium cyanide and copper sulphate; (*b*) by distillation of potassium cyanide with the potassium salt of the corresponding sulphonic acid, *e.g.* benzonitrile:

$$\underset{\text{Potassium Benzene Sulphonate.}}{C_6H_5SO_2OK} + KCN = C_6H_5CN + K_2SO_3.$$

(*c*) From the corresponding acid by distillation with lead sulphocyanate. The nitriles have many important reactions: (1) On hydrolysis they yield first acid amides and then acids. Thus with concentrated sulphuric acid they yield the amide, taking up one molecular proportion of water from the acid, and the amide, on boiling with water, yields the acid. They are also hydrolysed by boiling with alkalis:



Certain aromatic nitriles are either not hydrolysed at all or only very slowly, *e.g.* symmetrical trimethylbenzonitrile is very difficult to hydrolyse, while s-trimethyl-tricyano-benzene cannot be hydrolysed. This is attributed to spacial hindrance by the adjacent methyl groups:



(2) On reduction (sodium and alcohol) the nitriles yield amines:

$$\begin{matrix}CH_3\\ |\\ C\\ |||\\ N\end{matrix} + 4H = \underset{\text{Ethylamine.}}{\begin{matrix}CH_3\\ |\\ CH_2\\ |\\ NH_2\end{matrix}}$$

The method of preparation (1) combined with this reaction forms a method of passing up a homologous series of alcohols, etc.:

$$CH_3OH \rightarrow CH_3I \rightarrow CH_3CN \rightarrow CH_3CH_2NH_2 \xrightarrow{HNO_2} CH_3CH_2OH$$

(3) With hydrochloric acid and with hydrochloric acid and alcohol they form imide chlorides and ethers respectively:

$$CH_3C\begin{matrix}\diagup\!\!\diagup NH\\ \diagdown Cl\end{matrix} \text{ and } CH_3C\begin{matrix}\diagup\!\!\diagup NH\\ \diagdown OC_2H_5\end{matrix}$$

(4) With organic acids and anhydrides they form secondary and tertiary amides:

$$CH_3C\equiv N + \begin{matrix}CH_3CO\\ CH_3CO\end{matrix}\!\!>\!O = N\begin{matrix}\diagup OC.CH_3\\ -OC.CH_3\\ \diagdown OC.CH_3\end{matrix}$$

(5) They undergo polymerisation on treatment with sodium. *See* KETONES.

Nitrites (*Chem.*) Salts or esters of nitrous acid (*q.v.*) The inorganic nitrites are yellowish-white crystalline solids, all soluble in water; the least soluble of them, silver nitrite, dissolves in about 300 times its weight of cold water, but easily in hot water. They are decomposed on heating, giving off nitric oxide and nitrogen peroxide, and leaving the oxide or metal behind. In some cases a nitrate is certainly formed as intermediate product. They are easily decomposed by acids, liberating the unstable nitrous acid. Oxidising agents convert them into nitrates. The nitrites of potassium, sodium, and silver are described under the compounds of those metals. The organic nitrites are volatile, colourless, or pale yellow, pleasant smelling liquids. *See* AMYL NITRITE *and* ETHYL NITRITE. They are isomeric with the corresponding nitro-compounds. Their constitution is represented thus: $R-O.NO$, because they are easily hydrolysed to alcohols and nitrites; also on reduction they yield an alcohol and ammonia, *e.g.*

$$C_2H_5O.NO + HOK = C_2H_5OH + NO.OK$$
$$C_2H_5O.NO + 6H = C_2H_5OH + NH_3 + H_2O$$

Nitrobenzene (*Chem.*) $C_6H_5NO_2$. A slightly yellow liquid which smells like oil of bitter almonds, and is therefore used, though poisonous, as a flavouring agent under the name of essence of mirbane; melts at 3°, boils at 209°; nearly insoluble in water, but easily soluble in the usual organic solvents, such as alcohol, ether, acetic acid, benzene, etc.; specific gravity, 1·2. It is obtained by gradually adding a mixture of concentrated nitric and sulphuric acids

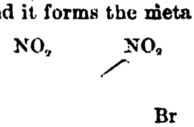
(12 parts to 18 parts) to benzene (10 parts), with constant stirring, and cooling so as to keep the temperature below 25° at first; when most of the acid has been added, the temperature may be allowed to rise, but not over 50°. After standing, the lower layer of acid is run away, and the nitrobenzene well washed by water, or if required very pure, distilled in steam; it can be dried over calcium chloride. On reduction with an acid reducing agent it yields aniline (*q.v.*); with a neutral reducing agent such as aluminium amalgam and water it yields, in ether solution, an intermediate product, phenylhydroxylamine. *See* NITROSO COMPOUNDS. With alcoholic potash or sodium amalgam and alcohol, etc., it yields azoxybenzene (*q.v.*):

$$2C_6H_5N\begin{smallmatrix}\nearrow O\\ \searrow O\end{smallmatrix} + 6H = C_6H_5.N - N.C_6H_5 + 3H_2O.$$
$$\qquad\qquad\qquad\qquad \diagdown O \diagup$$

See also QUINOLINE. On electrolytic reduction in strong acid solution it yields paramidophenol:

$$C_6H_5N\begin{smallmatrix}\nearrow O\\ \searrow O\end{smallmatrix} \rightarrow C_6H_5N\left\langle\begin{smallmatrix}H\\ OH\end{smallmatrix}\right. \quad HO.C_6H_4NH_2.$$

On further nitration it yields metadinitrobenzene, HNO_3, 70 : H_2SO_4, 100 : $C_6H_5NO_2$. 100 parts. Temperature 70° to 100°), which is a slightly yellowish crystalline solid melting at 90°. Nitrobenzene is only acted on by bromine and chlorine to form substitution products, when a halogen carrier, $FeCl_3$, is present, and it forms the meta derivative



Nitro-Compounds (*Chem.*) Compounds of the formula $R^N(NO_2)_N$, when R is an organic residue which may be of any degree of complexity, and N represents the valency of R. They are divided into two well defined groups, *viz.* (*a*) fatty nitro-compounds, (*b*) aromatic nitro-compounds. The fatty nitro-compounds cannot, as a rule, be obtained by the direct action of nitric acid on the hydrocarbon. In some of the higher paraffin hydrocarbons direct nitration can be effected by nitric acid, but the process is accompanied by oxidation. Thus normal hexane is nitrated by nitric acid when boiled with it for several days, yielding a mono- and a dinitrohexane; the higher paraffins are more easily nitrated, and the iso-paraffins still more easily. The nitroparaffins are usually obtained by the action of silver nitrite on an alkyl iodide, when they are usually obtained mixed with the isomeric nitrite, from which they can be separated by fractional distillation, the nitro-compound having the higher boiling point. They are colourless liquids, not hydrolysed by caustic soda as the nitrites are; on reduction they yield hydroxylamines, then amines. With alcoholic soda or sodium ethoxide, primary nitro-paraffins form sodium salts, which are explosive. Because of this salt formation it is assumed that the primary nitro-paraffins can have two isomeric forms; *e.g.*

$$(1)\ CH_3CH_2NO_2,\ \text{and}\ (2)\ CH_3C\begin{smallmatrix}\diagup H\\ \diagdown\!\diagdown NO.OH\end{smallmatrix}$$

Form (1) being stable, Form (2) being unstable and giving rise to the salts. The two forms have not been obtained in the case of the simple nitro-paraffins, but they have been obtained in the case of phenylnitro-methane:

$$(1)\ C_6H_5CH_2NO_2,\ (2)\ C_6H_5C\begin{smallmatrix}\diagup H\\ \diagdown\!\diagdown NO.OH\end{smallmatrix}$$

Form (2) is obtained by making the sodium salt and acidifying it, when Form (2) separates as a crystalline solid, while Form (1) is an oily liquid. *See* PSEUDO-ACIDS. An interesting reaction of the sodium salt of nitro-methane is the formation of mercury fulminate when its solution is added to a solution of mercuric chloride:

$$2\begin{smallmatrix}H\\ H\end{smallmatrix}\!\!>\!C = NO.ONa + HgCl_2 = 2H_2O + (C = NO)_2Hg + 2NaCl.$$

The action of nitrous acid on the nitro-paraffins is dependent on the position of the nitro-group. Primary nitro-paraffins yield nitrolic acids, secondary pseudo-nitrols, tertiary are unacted on. The equations make this statement clear:

$$\underset{\text{Nitro ethane.}}{CH_3.C\begin{smallmatrix}\diagup H\\ - H\\ \diagdown NO_2\end{smallmatrix}} + ON.OH = \underset{\text{Methyl Nitrolic Acid.}}{\overset{CH_3}{\overset{|}{C}}\begin{smallmatrix}\diagup\!\diagup NOH\\ \diagdown NO_2\end{smallmatrix}} + H_2O$$

$$\underset{\text{Isonitropropane.}}{(CH_3)_2C\left\langle\begin{smallmatrix}H\\ NO_2\end{smallmatrix}\right.} + ON.OH = \underset{\text{Isopropylpseudonitrol.}}{(CH_3)_2C\left\langle\begin{smallmatrix}NO\\ NO_2\end{smallmatrix}\right.} + H_2O$$

$$\underset{\text{Tertiary Nitrobutane.}}{(CH_3)_3C.NO_2} + ON.OH = \text{No action.}$$

The nitrolic acids are colourless, but yield red sodium salts, while the pseudo-nitrols are blue. *See* NITROSO-COMPOUNDS. The aromatic nitro-compounds are usually obtained by direct nitration; that is to say, by the direct action of nitric acid of various strengths, or by the direct action of a mixture of nitric and sulphuric acids, the sulphuric acid acting as a dehydrating agent, on the compound whose nitro-derivative is required; examples of direct nitration are given under nitro-benzene and picric acid. But some aromatic compounds cannot be directly nitrated, *e.g.* the amines. To nitrate amines they are converted into salts or acid derivatives. Thus to nitrate aniline it may be converted into sulphate by addition of a large excess of sulphuric acid and then nitrated, or it may be converted into acetanilide, and the acetanilide nitrated. On nitrating benzene and its derivatives certain regularities are observed. If one nitro-group is already present a second nitro-group will assume the meta-position with respect to the first; if other groups are present, the rule is as follows: with an unsaturated group already present the nitro-group goes chiefly into the meta-position, but with a saturated group it takes the para- or ortho-position; *e.g.* groups

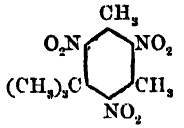
$$-N\begin{smallmatrix}\diagup O\\ \diagdown\!\diagdown O\end{smallmatrix},\ -C\begin{smallmatrix}\diagup OH\\ \diagdown\!\diagdown O\end{smallmatrix},\ -C\begin{smallmatrix}\diagup H\\ \diagdown\!\diagdown O\end{smallmatrix},\ -S\begin{smallmatrix}\diagup\!\diagup O\\ \Leftarrow O\\ \diagdown OH\end{smallmatrix},\ -C \equiv N,$$

are unsaturated; groups

$$Cl,\ Br,\ -N\left\langle\begin{smallmatrix}R\\ H\end{smallmatrix}\right.,\ -OH,\ -OCH_3,\ -CH_2R,$$

are saturated (R is hydrogen or any monovalent element or group). The aromatic nitro-compounds are usually yellow liquids or solids of pleasant smell. But paranitrophenol is white, and only its salts are coloured. Nitrobenzene smells of almonds, and

1 : 3 : 5-dimethyltertiarybutyltrinitrobenzene has a powerful smell of musk (artificial musk).



The nitro-compounds of aromatic substances are very important because on reduction they yield amines which are of extreme importance in dye making and in the preparation of other aromatic compounds. *See* DIAZO-REACTION. For the reactions of a typical nitro-compound *see* NITROBENZENE. *See also under* NAPHTHALENE *and* NAPHTHOLS.

Nitrogen (*Chem.*) N. Atomic weight, 14. A colourless gas; no smell; melts at $-214°$; boils at 194°; slightly soluble in water (100 cc. water dissolve $1\frac{3}{8}$ cc. at 15° and 760 mm.) Unites, but only at high temperature, with a large number of other elements. Examples: (1) With hydrogen under the influence of electric sparks, where the yield of ammonia is only about 0·2 per cent., owing to the reversible character of the reaction. If, however, a little dilute sulphuric acid is present to take up the ammonia, the whole of the nitrogen can be converted into ammonia. (2) With oxygen. When electric sparks from a large induction coil are passed in air the oxygen burns in the nitrogen to form nitric oxide. *See* NITRIC ACID. (3) With magnesium. When nitrogen is passed over heated magnesium the nitride is formed. Boron, cerium, and lanthanum all burn in the gas when heated, the two last at the moderate temperature of 260°. Nitrogen forms about four-fifths by volume of the atmosphere (*q.v.*); it is, in combination, a necessary constituent of all plants and animals, and certain plants are able through the agency of bacteria to assimilate the element directly. To obtain it chlorine is passed through excess of the strongest ammonia.

$$\left\{\begin{array}{l} 2NH_3 + 3Cl_2 = N_2 + 6HCl \\ 6NH_3 + 6HCl_2 = 6NH_4Cl \end{array}\right\}$$

Or strong solutions of sodium nitrite and ammonium chloride are mixed in molecular proportions, and the mixture is gently warmed.

$$NaNO_2 + NH_4Cl = NaCl + 2H_2O + N_2.$$

Many attempts have been made to utilise the atmospheric nitrogen—for example, in the preparation of nitric acid (*q.v.*) When nitrogen is passed over heated calcium carbide a mixture of calcium cyanide and cyanamide results. The latter on heating with carbon and common salt is changed to calcium cyanide. From calcium cyanide either alkaline cyanides can be prepared by the action of alkaline carbonates or ammonia can be prepared by heating it with water under pressure:

$$Ca(CN)_2 + 3H_2O = CaCO_3 + 2NH_3.$$

Nitrogen Chloride (*Chem.*) NCl_3. A pale yellow liquid; its sp. gr. is about 1·6 (it sinks very slowly in a solution of ferric sulphate, sp. gr. 1·578. Porret, Wilson, and Kirk, 1813); very explosive; its vapour strongly affects the eyes and mucous membrane of the respiratory passages, so that it is a dangerous substance to work with apart from its properties as an explosive. On heating, it explodes at 95°. Direct sunlight or burning magnesium wire causes it to explode. It is decomposed by ammonia into nitrogen and hydrochloric acid, and by means of this reaction Gattermann analysed his pure nitrogen chloride. Contact with organic matter, such as wood or turpentine, causes it to explode instantly. But a solution in benzene (5 to 10 per cent.) has been used as a chlorinating agent; thus it converts aniline, or, for a better yield, aniline hydrochloride, into trichloraniline hydrochloride. It is best prepared by the action of chlorine on a warm and saturated solution of ammonium chloride; the oil so obtained is washed with water, then treated with a stream of chlorine; finally it is separated, washed, dried over fused calcium chloride. It can also be obtained by the electrolysis of a solution of ammonium chloride.

Nitrogen in Food. Is essential for the growth, maintenance, repair, and functional activity of the tissues. The amount of nitrogen in diet for an adult in ordinary work varies from 250 to 350 grains. In the best diets the proportion of nitrogen to carbon is about 1 to 15. *See* FOODS.

Nitrogen Iodide (*Chem.*) $NI_3 . NH_3$. The pure substance NI_3 has not been prepared. The substance of the above formula ($NI_3 . NH_3$) is a black powder, or, when prepared as described below, a lustrous reddish crystalline solid. It easily explodes on percussion or friction when dry; it is also decomposed by light; in the visible spectrum the red rays decompose it fastest. The products of decomposition by light are nitrogen and ammonium iodide and iodate. It is decomposed by water, acids, and alkalis. The reactions usually proceed quietly in the cold, but with explosion on warming. The explanation of its modes of formation and decomposition is to be found in the reversible reaction—

$$3NH_4OI = NI_3NH_3 + NH_4OH + 2H_2O.$$

Hence nitrogen iodide is formed in those reactions where ammonium hypoiodite might be expected, and the first step in its decomposition is the reformation of ammonium hypoiodite. Thus nitrogen iodide is decomposed by caustic potash as follows:

$$NH_3NI_3 + 3KOH = 2NH_3 + 3KOI$$
$$3KOI = KIO_3 + 2KI.$$

It can be prepared by the action of ammonia on iodine or in crystallised state as follows: iodine (100 gr.), concentrated hydrochloric acid (300 cc.), and concentrated nitric acid (28 cc.) are heated not above 40° till all the iodine is dissolved, and a solution of iodine chloride, ICl, is formed; it is then boiled to expel nitrosyl chloride. A quantity of this solution containing 12·7 gr. of iodine is made up to 1 litre; this solution is used 15 cc. at a time, each lot is added to 100 cc. of 3 per cent. caustic potash, and then 10 cc. of strongest ammonia are added, and the whole shaken. The iodide crystallises out (Chattaway & Orton). Dr. Chattaway (private communication) has prepared tribenzylamine from nitrogen iodide by acting upon it with benzyl iodide in presence of magnesium and ether, thus showing that it contains the group NI_3.

Nitrogen Oxides (*Chem.*) (1) NITROUS OXIDE, N_2O, LAUGHING GAS. The anhydride of hyponitrous acid. A colourless heavy gas; no smell. Produces temporary unconsciousness when inhaled, hence its use in minor surgical operations; and it does this even when mixed with oxygen. Melts at $-99°$; boils at $-90°$. Somewhat soluble in water (78 cc. in 100 cc. at 15° and 760 mm.) Substances which burn in oxygen burn in nitrous oxide when heated to such

a temperature as will decompose it; and as the gas is an endothermic compound, the heat evolved in such combustions is greater than that evolved in an equivalent quantity of oxygen by the heat of formation of the nitrous oxide. The products are the oxide of the substance burnt and a volume of nitrogen equal to the volume of nitrous oxide employed. It is obtained by the decomposition of the corresponding acid, hyponitrous acid (*q.v.*); but hyponitrous acid has not yet been prepared from nitrous oxide; by reducing a solution of sodium nitrite with sodium amalgam at a low temperature; by the action of dilute nitric acid on zinc. But to obtain it in quantity ammonium nitrate is heated at 240°, $NH_4NO_3 = N_2O + 2H_2O$. For inhalation the nitrate used should be free from chloride, and the gas obtained from it should be passed through ferrous sulphate solution to remove traces of nitric oxide which may be present. (2) NITRIC OXIDE, NO. A colourless gas. Melts at −167°; boils at −154°. Very slightly soluble in water; only decomposed by heat at a very high temperature. Substances which burn in oxygen burn in this gas when heated to a sufficiently high temperature to decompose it, the oxygen forming oxides and the nitrogen being, as a rule, set free, and measuring half the volume of the nitric oxide taken. It unites with oxygen to form nitrogen peroxide, NO_2, unless both gases are absolutely dry, when no union occurs. It is absorbed by solutions of ferrous salts, chromous salts, stannous salts, and mercurous salts. With ferrous sulphate a dark brown solution is obtained, the formation of which serves as a test for nitric acid (*see* below) and as a means of purifying nitric oxide (*see* below). Nitric oxide is perfectly absorbed by a strong solution of sodium sulphite containing some caustic soda, forming sodium hyponitrososulphate, $Na_2N_2O_2SO_3$, the best method of absorption in gas analysis. It is reduced to nitrous oxide by zinc in presence of water. Solution of stannous hydroxide in excess of caustic potash reduces it to potassium hyponitrite. Nitric oxide is formed by the direct union of its elements. Usually it is obtained by the action of copper on nitric acid (*q.v.*), but it is then impure. To purify it the gas is passed into a saturated ferrous sulphate solution, and nitrous oxide and nitrogen escape, while higher oxides are decomposed; the resulting brown black solution is heated, and gives off pure nitric oxide. A method of preparing the pure gas directly is to heat ferrous sulphate and sodium nitrate together with somewhat dilute sulphuric acid:

$$\left\{\begin{array}{c} 2NaNO_3 + 2H_2SO_4 = \\ 2NaHSO_4 + 2HNO_3 \\ 2HNO_3 + 6FeSO_4 + 3H_2SO_4 = \\ 3Fe_2(SO_4)_3 + 2NO + 4H_2O \end{array}\right\}$$

(3) NITROGEN TRIOXIDE, N_2O_3 (anhydride of nitrous acid). Not known in pure condition in the gaseous state, for at ordinary temperatures it decomposes nearly completely into nitric oxide and nitrogen peroxide. The blue liquid obtained by condensation of the red fumes evolved from arsenious oxide or starch and nitric acid contains this oxide, but it is not pure, as it undergoes dissociation at very low temperatures. When electric sparks are passed through liquid air a green solid is formed, which remains as a bluish amorphous powder when the air is evaporated. The solid melts at −111° to a deep blue liquid, which easily evolves nitric oxide. Analysis of the solid shows it to be pure nitrogen trioxide. (4) NITROGEN PEROXIDE OR TETROXIDE, NO_2 or N_2O_4. A liquid which boils at 21°. Its colour depends on the temperature. At −10° it is a colourless solid; a little above this it melts to a yellow liquid, becoming red as the temperature rises: above its boiling point it is a red brown gas, which deepens in colour as it is heated, till it appears nearly black (140°). At 140° it has the formula NO_2; at 26·7° it consists of only 20 per cent., NO_2; the rest is N_2O_4. The liquid has the formula N_2O_4, but this dissociates on diluting its chloroform solution. About 620° the gas becomes colourless, forming nitric oxide and oxygen. Anhydrous liquid nitrogen tetroxide is a good solvent for many organic compounds, such as the saturated hydrocarbons, nitro-compounds, many acids; but unsaturated hydrocarbons, hydroxy-compounds, and amines are attacked. Example: Naphthalene gives 1:5 dinitronaphthalene, and phenol gives 2 : 4 dinitrophenol. It is decomposed by water:

$$3NO_2 + H_2O = 2HNO_3 + NO.$$

Phosphorus, charcoal, and potassium will burn in it. When moist it attacks mercury and many other metals forming nitrates. It is usually obtained by heating lead nitrate,

$$Pb(NO_3)_2 = PbO + 2NO_2 + O.$$

The oxygen is separated by passing the gases through a tube immersed in a freezing mixture, from which the oxygen escapes uncondensed. To obtain large quantities, lumps of arsenious oxide are treated with concentrated sulphuric acid and fuming nitric acid, cooling at first, then warming till the reaction stops. The gas is condensed, dehydrated by phosphorus pentoxide, dry oxygen passed through it, and finally it is distilled. (5) NITROGEN PENTOXIDE, N_2O_5 (the anhydride of nitric acid). A white crystalline solid. Melts at 30°; decomposes easily into nitrogen peroxide and oxygen; unites with water to form nitric acid. It is formed by the action of ozone on nitrogen peroxide; by the action of dry chlorine on dry silver nitrate; and by distilling the strongest nitric acid (*q.v.*) with phosphorus pentoxide.

Nitrogen Sulphides (*Chem.*) Two are known: (1) Nitrogen sulphide, N_4S_4, obtained by the action of ammonia on sulphur chloride; forms yellowish red crystals at 135°; it explodes when struck; melts with decomposition at 158°. Heated with carbon disulphide at 100° under pressure, it yields (2) Nitrogen pentasulphide, N_2S_5—a red liquid which does not wet glass; melts at 10°; insoluble in water, soluble in usual organic solvents; decomposed by light into N_4S_4 and S. Boiled with water or alkalis it gives ammonia and sulphur. A trace of alcoholic potash gives a transient violet red coloration (Test).

Nitroglycerine (*Chem.*) $\begin{array}{c} CH_2ONO_2 \\ | \\ CHONO_2 \\ | \\ CH_2ONO_2 \end{array}$. Is not a nitro-compound, but the trinitrate of glycerine. It is a colourless liquid; sp. gr. 1·6; melts about 10°; no smell; sweet taste; used in medicine, as it acts like amyl nitrite; poisonous; insoluble or nearly so in water, but soluble in the usual organic solvents; it can be distilled in steam. On heating, it volatilises even at 100°, and about 180° it explodes; it is also exploded by a blow or by a detonator, especially mercury fulminate. It can be burned without explosion if it is kept warm, but it explodes if

temperature reaches 180°. Nitroglycerine is hydrolysed by alcoholic potash to glycerine and potassium nitrate, thus behaving like a true nitric acid ester. To prepare nitroglycerine on a large scale a spray of pure glycerine is driven by compressed air into a mixture of pure concentrated sulphuric acid and nitric acid; as heat is developed in the process the temperature is carefully regulated by cooling with water which runs in leaden coils in the nitrating vessels. After the operation is over the nitroglycerine collects above the acids, whence it is run into water and thoroughly washed; then with a weak alkaline solution to remove the last traces of acid; finally it is dried by filtering through felt. When in a pure state it can be kept with safety. Nitroglycerine is used in the manufacture of explosives such as dynamite, blasting gelatine, cordite, and others less well known.

Nitrohydrochloric Acid (*Chem.*) Another name for Aqua Regia (*q.v.*)

Nitromuriatic Acid. *See* Aqua Regia.

Nitroso-Compounds (*Chem.*) Compounds of the formula $R-NO$, where R may be a monovalent residue from many different classes of compounds such as hydrocarbons, amines, phenols, nitro-compounds, and many others, *e.g.* nitroso-benzene, C_6H_5NO; dimethylnitrosamine, $(CH_3)_2N.NO$; nitrosophenol,

$$C_6H_4\left\langle{OH \atop NO}\right. ;\ \text{propylpseudonitrol}, (CH_3)_2C\left\langle{NO \atop NO_2}\right. .$$

Nitroso-compounds are obtained in a variety of ways, the following being only a few of them: (1) Oxidation of certain amines by Caro's acid. *See* Sulphur Compounds. The amines which undergo this reaction are those having the nitrogen atom united to a tertiary carbon atom, and aromatic amines such as aniline—

$$(CH_3)_3C.N\left\langle{H \atop H}\right. \rightarrow (CH_3)_3C.N\left\langle{OH \atop H}\right. \rightarrow$$

Tertiarybutylamine.

$$(CH_3)_3C.N=O$$

$$C_6H_5.N\left\langle{H \atop H}\right. \rightarrow C_6H_5N\left\langle{OH \atop H}\right. \rightarrow C_6H_5-N=O$$

Aniline. β-phenylhydroxylamine. Nitrosobenzene.

(2) Nitro-compounds are reduced to hydroxylamines by aluminium amalgam or by electrolysis in acetic acid solution, and the hydroxylamines are oxidised by chromic acid to nitroso-compounds.

$$C_6H_5N\left\langle{\!/\!/O \atop \backslash\backslash O}\right. \rightarrow C_6H_5N\left\langle{OH \atop H}\right. \rightarrow C_6H_5.NO.$$

(3) Action of nitrosylchloride on unsaturated hydrocarbons, *e.g.*

$$(CH_3)_2C=CHCH_3 \xrightarrow{NOCl} {CH_3 \atop CH_3}\!\!>\!C(Cl)-C\left\langle{CH_3 \atop {H \atop NO}}\right.$$

Trimethylethylene. Trimethylethylenenitrosochloride.

This reaction is very important in the chemistry of the Terpenes (*q.v.*) (4) Nitrous acid reacts directly with secondary amines and with nitro-compounds derived from secondary alcohols to form nitrosamines and pseudonitrols respectively:

$$(C_2H_5)_2NH + HO.NO = (C_2H_5)_2N.NO + H_2O$$

$$(CH_3)_2C\left\langle{NO_2 \atop H}\right. + HONO = (CH_3)_2C\left\langle{NO_2 \atop NO}\right. + H_2O$$

This reaction is important in distinguishing secondary from primary and tertiary amines, and secondary from primary and tertiary alcohols. A similar reaction to that with the secondary amines occurs with nitrous acid if one of the alcohol radicals is replaced by an acid radical, *e.g.*

$${CH_3CO \atop C_6H_5}\!\!>\!NH + HO.NO = {CH_3CO \atop C_6H_5}\!\!>\!N.NO + H_2O.$$

Acetanilide. Nitrosoacetanilide.

The fatty *tertiary* amines do not react with nitrous acid; but the aromatic dialkylamines form paranitroso-compounds, *e.g.*

$$N\left\langle{CH_3 \atop {CH_3 \atop C_6H_5}}\right. + HO.NO = N\left\langle{CH_3 \atop {CH_3 \atop C_6H_4.NO}}\right. + H_2O$$

Dimethylaniline. Paranitrosodimethylaniline.

See Gallocyanine *and* Neutral Red. (5) Nitrosophenols result from the action of nitrous acid on phenols, while their ethers are obtained by method (1) from aminophenolethers. The nitroso-compounds are mostly blue or green in colour when in solution or in a state of fusion; but in the solid state they are white. This is due to the fact that they readily polymerise to bimolecular compounds; but the nitroso-compounds of secondary amines are yellow oils. *E.g.* nitrosobenzene is a white solid which melts at 68° to a green liquid; paranitrosophenol is a white solid which decomposes on melting, but is soluble in water or alcohol, forming a green solution; propylpseudonitrol is a white solid which melts at 76° to a blue liquid; it dissolves in cold benzene to a colourless solution, which turns blue slowly on standing and quickly on warming. Many nitroso-compounds easily pass into the so-called iso-nitroso-compounds, which are really oximes. *E.g.*

$${CH_3 \atop {CH_3 \atop Cl}}\!\!>\!C-C\left\langle{CH_3 \atop {H \atop NO}}\right. \rightarrow {CH_3 \atop {CH_3 \atop Cl}}\!\!>\!C-C\left\langle{CH_3 \atop NOH}\right. .$$

Analogous to this transformation of fatty nitroso-compounds is no doubt the tautomeric behaviour of paranitrosophenols as quinonemonoximes.

$$C_6H_4\left\langle{OH \atop NO}\right. \rightarrow C_6H_4\left\langle{\!/\!/O \atop \backslash\backslash NOH}\right.$$

When nitroso-compounds are carefully reduced they yield hydroxylamines; on strong reduction, amines.

$$C_6H_5N=O \rightarrow C_6H_5N\left\langle{OH \atop H}\right. \quad C_6H_5N\left\langle{H \atop H}\right.$$

$$(CH_3)_2N.N=O \rightarrow (CH_3)_2N\ N\left\langle{OH \atop H}\right.$$

$$(CH_3)_2N.N\left\langle{H \atop H}\right.$$

Dimethylhydrazine.

$$\rightarrow (CH_3)_2NH + NH_3$$

Dimethylamine.

On oxidation, nitroso-compounds are in many cases converted into nitro-compounds. *E.g.*

$$(CH_3)_2C\left\langle{NO_2 \atop NO}\right. + O = (CH_3)_2C\left\langle{NO_2 \atop NO_2}\right.$$

ββ-Dinitropropane.

$$C_6H_5NO + O = C_6H_5NO_2$$

Nitrobenzene.

As a common example of the application of nitroso-compounds may be mentioned the laboratory method of separating aniline from methylaniline. The mixture is made into hydrochloride and treated with nitrous acid, when the aniline forms diazobenzenechloride, and the methylaniline forms the nitroso-compound, which can be separated by extraction with ether and methylaniline, obtained from it by reduction with tin and hydrochloric acid. Other examples of their use have been given above. Paranitrosodimethylaniline in particular is used in making dyes.

Nitrosulphonic Acid (*Chem.*) $SO_2\left\langle\begin{matrix}NO_2\\OH\end{matrix}\right.$. Also called Nitrosyl Sulphuric Acid and Leaden Chamber Crystals. Nearly colourless crystalline solid; melts at 30° with decomposition; decomposed by cold water.

$$SO_2\left\langle\begin{matrix}NO_2\\OH\end{matrix}\right. + HOH = SO_2\left\langle\begin{matrix}OH\\OH\end{matrix}\right. + NO.OH$$

At a higher temperature the nitrous acid decomposes, giving its unstable anhydride:

$$2NO.OH = N_2O_3 + H_2O = NO_2 + NO + H_2O.$$

The acid is found in the leaden chambers used in the manufacture of sulphuric acid when steam is deficient. It can be prepared by saturating nitric acid with sulphur dioxide or sulphuric acid with nitrosyl chloride:

$$NO_2.OH + SO_2 = SO_2\left\langle\begin{matrix}NO_2\\OH\end{matrix}\right.$$

$$NOCl + SO_2\left\langle\begin{matrix}OH\\OH\end{matrix}\right. = SO_2\left\langle\begin{matrix}NO_2\\OH\end{matrix}\right. + HCl$$

It is also formed in solution in sulphuric acid in the Gay-Lussac tower, used to absorb the nitrogen peroxide carried away by the escaping leaden chamber gases in the manufacture of sulphuric acid.

$$SO_2\left\langle\begin{matrix}OH\\OH\end{matrix}\right. + 2NO_2 = SO_2\left\langle\begin{matrix}NO_2\\OH\end{matrix}\right. + NO_2OH$$

Nitrosyl Chloride (*Chem.*) ON.Cl. A yellow gas; melts about −60° and boils at −8°. Decomposed by water and by alkalis:

$$ON.Cl + HOH = ClH + ON.OH.$$

Unites with many unsaturated organic compounds to form nitroso-compounds (*q.v.*); *e.g.*

$$(1)\ \begin{matrix}CH_3\\CH_3\end{matrix}\Big> C = C\Big<\begin{matrix}CH_3\\H\end{matrix} + ONCl =$$

Trimethylethylene.

$$\begin{matrix}CH_3\\CH_3\\Cl\end{matrix}\Big> N - N\Big<\begin{matrix}Cl\\H\\NO\end{matrix}$$

Trimethylethylenenitrosochloride.

(2) It unites with many terpenes (*q.v.*) to form terpenenitrosochlorides. Nitrosyl chloride is formed by direct union of nitric oxide and chlorine in the presence of light and a catalytic agent such as carbon; but it is best obtained by warming a mixture of ordinary concentrated nitric and hydrochloric acids (1 vol. to 4 vols.)

$$HO.NO_2 + 3HCl = NOCl + 2H_2O + Cl_2,$$

drying the gases over calcium chloride, and passing them into concentrated sulphuric acid, which only unites with the nitrosyl chloride, which may be obtained from its solution in the acid by warming with dry common salt. The gas is condensed in a tube immersed in a freezing mixture.

Nitrous Acid (*Chem.*) HNO_2 or ON.OH. Unknown in pure condition. It is capable of existing in aqueous solution as a blue liquid at low temperatures; but if the temperature rises it decomposes: $3ON.OH = 2NO + HNO_3 + H_2O$. It is a very important reagent in organic chemistry. *See* DIAZO-REACTIONS *and* NITROSO-COMPOUNDS. When required as a reagent it is generated by acting on a nitrite with an acid. ON.ONa + HCl = ON.OH + NaCl.

Nobling (*Met.*) *See* SHINGLING.

Noblins (*Met.*) The name for blocks of puddled iron 10 or 12 in. square and 1½ to 2½ in. thick, obtained by shingling (*q.v.*) the puddled balls of iron under a helve or hammer. Also called STAMPINGS. *See* STAMPS.

Nocturne (*Paint.*) The term applied to a painting representing some impression of night.

Nodal Points of a Lens (*Light*). These are points defined by the property that if the direction of a ray approaching the lens passes through the first nodal point (when produced), it will emerge as if it came from the second nodal point, and will also be parallel to the incident ray. When the media are the same on both sides of the lens, the nodal points coincide with the Principal Points (*q.v.*)

Node (*Sound.*) A node is a point in a vibrating body (or medium) which remains permanently at rest. In a stretched string, the ends are always nodes; if the string be vibrating in two halves, so as to emit its first overtone, the centre is also a node. In an organ pipe, a closed end is always a node.

Nodes (*Astron.*) The intersection of the orbit of one planetary body with that of another; in particular, the intersection of the moon's orbit with the ecliptic.

Nogging Pieces (*Carp. and Join.*) The horizontal pieces in a quarter or brick nogged partition.

Noil (*Worsted Manufac., etc.*) Short neps of fibres removed in the process of combing. A valuable material, and used in the woollen carding. *See* NEP *and* CARDING.

Noiling Motion (*Worsted Manufac., etc.*) The motion on the combing machine for extracting short fibre. This is done constantly throughout the process of combing.

Nomenclature, Chemical. Names of metals usually end in *-um* or *-ium*, except the names of a few common metals such as iron, copper, tin, etc.; in these cases the Latin names end in *-um*, *e.g.* Ferrum, Cuprum, Stannum. Selenium and Tellurium, which are not true metals, have also this termination; it has been proposed to change their names to Selenion and Tellurion. Compounds of two elements are named by taking the name of one of the elements and putting that first, then altering the termination of the second element to *-ide*, and putting the altered name second; this rule is followed unless the compound has a common name. When the two elements unite in more than one proportion the proportions are indicated by using Latin or Greek numerical prefixes before one or both the names. Examples: Water is sometimes called hydrogen monoxide; a compound containing more oxygen is called hydrogen dioxide or hydrogen peroxide. *See* OXIDES, CHLORIDES, SULPHIDES, NITRIDES, *etc.* Acids have often common names, *e.g.* nitric acid, HNO_3; acetic acid, CH_3COOH. Acids containing only two elements, one of which must be hydrogen, are named as in the case of hydrochloric acid, HCl; hydrobromic acid, HBr, etc. Acids composed of three elements, of which oxygen is one, are named so as to indicate the amounts of oxygen they contain as follows:

Perchloric acid, $HClO_4$. Phosphoric acid, H_3PO_4.
Chloric acid, $HClO_3$. Phosphorous acid, H_3PO_3.
Chlorous acid, $HClO_2$. Hypophosphorus acid, H_3PO_2.
Hypochlorous acid, HClO.
Persulphuric acid, $H_2S_2O_8$. Nitric acid, HNO_3.

Sulphuric acid, H_2SO_4. Nitrous acid, HNO_2.
Sulphurous acid, H_2SO_3. Hyponitrous acid, HNO.
Hyposulphurous acid, H_2SO_2.

Salts derived from these acids are named by stating the metal first, then the acid with its termination changed to *-ate* if it ends in *-ic*, and to *-ite* if it ends in *-ous*. Example :

Nitric acid forms potassium nitrate.
Nitrous acid forms potassium nitrite.
Hyponitrous acid forms potassium hyponitrite.

Some metals combine with the same acid in different proportions: in this case the salt containing the greater proportion of metal is named by changing the termination of the metal to *-ous*. Example :

Mercurous sulphate, Hg_2SO_4.
Mercuric sulphate, $HgSO_4$.
Ferrous nitrate, $Fe(NO_3)_2$.
Ferric nitrate, $Fe(NO_3)_3$.

See also ANHYDRIDE, HYDROXIDE, ACID, SALT, ALKALI. In Organic Chemistry the nomenclature is very complex. Most *classes* of organic compounds are briefly described under the corresponding headings. *See for example* HYDROCARBONS, ALCOHOLS, ALDEHYDES, KETONES, PARAFFINS, ORTHO-, META-, *and* PARA-COMPOUNDS, OXIMES, AMINES, NITRILES. The Geneva or International System of Nomenclature may be briefly described. The paraffin hydrocarbons have names which end in *-ane*. *See* PARAFFINS. When the chain is branched, the longest straight chain is taken as the parent substance and the position of the substituting group is given by a number : if the substituting group has itself substituents which are paraffin residues the termination of the substituent is changed from *-ane* to *-o*, and its position indicated by a number placed as an index above the number of the first substituting group, the numbering starting from the carbon atom attached to the parent chain. Example :

$$\begin{array}{ccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ CH_3 . & CH_2 . & CH_2 . & CH . & CH_2 . & CH_2 . & CH_3 \\ & & & | & & & \\ & & & 4^1CH . CH_3 & & & \\ & & & | & & & \\ & & & 4^2CH^3 & & & \end{array}$$

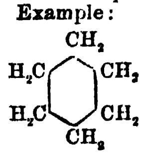
would be called metho-4^1-ethyl-4-heptane. Names of alcohols end in *-ol*, the position of the $-OH$ group being indicated by a number. Example :

$$\begin{array}{ccc} CH_3 & CH_3 & CH_2OH \\ | & | & | \\ CHOH & CHOH & CH_2 \\ | & | & | \\ CH_3 & CH_2OH & CH_2OH \end{array}$$

Propane-2-ol. Propane-1 : 2-diol. Propane-1 : 1^1-diol.

Aldehydes have names ending in *-al*.
Ketones have names ending in *-one*.

Amines are named as amino-substitution products of the hydrocarbons; saturated ring hydrocarbons are named after the corresponding paraffins with the prefix cyclo. Example:

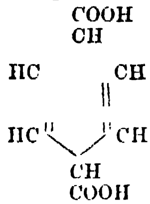


Cyclohexane.

Unsaturated hydrocarbons containing ethylene linkings have names ending in *-ene*, and the number of double linkings is indicated by a numerical prefix, the positions of the double bindings being indicated by numbers placed after the temination *-ene*. Example : Dimethyl, 2 : 6 ; heptadiene, 4 : 6.

$$\begin{array}{ccccccccccccc} 1 & & 2 & & 3 & & 4 & & 5 & & 6 & & 7 \\ CH_3 . & & CH & - & CH_2 & - & CH & = & CH & - & C & = & CH_2 . \\ & & | & & & & & & & & | & & \\ & & CH_3 & & & & & & & & CH_3 & & \end{array}$$

Acids have names ending in *-oic* and derived from the corresponding hydrocarbon. Example : Formic acid, HCOOH, would be called methanoic acid. An important method of indicating double linkings in the benzene ring due to von Baeyer must be mentioned. The Greek letter Δ indicates a double binding, and, starting from position 1 in the ring, the position of the double binding is indicated by a number placed after the letter, the number indicating the first carbon atom reached, bearing the double linking. Example :

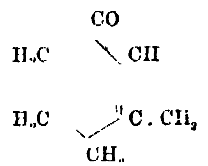


Δ 2 : 5 dihydroterephthalic acid.

General examples : Triacetylmethylol-2-nitro-2-propandiol-1-3.

$$\begin{array}{c} CH_2O . COCH_3 \\ | \\ O_2N . C . CH_2O . COCH_3 \\ | \\ CH_2O . COCH_3 \end{array}$$

3-methyl-Δ^2-keto-R-hexene. (R stands for ring or cyclo).



Nominal Horse Power (*Eng.*) The amount of power which an engine is declared by the designers or manufacturers to develop. *See* INDICATORS (*Eng.*)

Non (*Music*). Not.

Non-Conductor (*Elect.*) *See* INSULATING MATERIAL, *etc.*

Nonet (*Music*). A composition for nine voices or instruments.

Non-Inductive Circuit (*Elect.*) An electric circuit which possesses a very small amount of inductance (*q.v.*); no circuits are absolutely non-inductive, but the term is applied to those in which the inductance is negligible.

Non-Metals (*Chem.*) The common non-metals are : Hydrogen, Fluorine, Nitrogen, Oxygen, Chlorine, Bromine, Boron, Carbon, Silicon, Phosphorus, Sulphur, Arsenic, Iodine. Much less common is Selenium. Tellurium may be classed as a metalloid ; that is, it has partly metallic and partly non-metallic properties. The first five are gases, bromine is a liquid, the rest are solids. They all form gaseous hydrides ; that is, compounds with hydrogen. They are bad conductors of electricity with the exception of carbon ; they are bad conductors of heat and not malleable or ductile. The majority form chlorides, which are decomposed by water giving acids. They

all combine with oxygen except fluorine, and the great majority of these oxides give acids with water; water (*q.v.*) is both an acid and an alkali. Nitric oxide and carbon monoxide have no acid properties. The inert gases, Argon, Helium, etc., must be regarded as forming a class by themselves, as, on account of their wanting chemical activity, they cannot be classed either as metals or non-metals.

Nonpareil (*Typog.*) Type between emerald and pearl. *See* TYPE.

Non-Pathogenic Bacteria. *See* BACTERIA.

Non-Slipping Tyres (*Cycles, Motors*). *See* TYRES.

Non-Slip Stone. *See* ARTIFICIAL STONE.

Noon (*Astron.*) The moment of time when the sun is on the meridian. The astronomical day commences at noon.

Nopalea (*Botany*). A plant of great interest (*Nopalea coccinellifera*; order, *Cactaceæ*). It is cultivated principally in Mexico and other warm parts of America, and in addition to producing an edible fruit is used for rearing cochineal insects.

Nordhausen Sulphuric Acid (*Chem.*) *See under* SULPHUR COMPOUNDS.

Normal (*Math.*) The NORMAL to a curve is a line drawn from a point on the curve perpendicular to the TANGENT (*q.v.*) to the curve at the same point.

—— (*Min.*) The Normal of a crystal face is a line through the origin, perpendicular to the plane of the face.

Normal Salt (*Chem.*) *See* SALTS.

Normal Solution (*Chem.*) *See* VOLUMETRIC ANALYSIS.

Norman Architecture. The architecture of England between the years 1066 and 1189 A.D. It is also known as English Romanesque. The principal features of this style are as follows:—*Mouldings:* Simple, bold, not undercut, and frequently enriched. *See* BEAK HEAD, BILLET, CHAIN, *and* STAR MOULDING, CHEVRON. *Capitals:* Usually of the cushion type, and frequently carved. *See* CUSHION CAPITAL. *Piers:* Heavy square or cylindrical masses at first, but as the style developed the piers became lighter, and banded shafts were used. *Arches:* Semicircular, frequently richly moulded. *Doorways:* These are usually the most ornate features in the design, the arches being richly moulded, and clustered shafts used in the jambs. *Windows:* Semicircular headed, and frequently arranged in pairs with a shaft between. *Vaults:* Barrel vaults, groined vaults, and ribbed vaults were used, stilted and horseshoe arches being used in oblong bays. *Carving:* The carving was at first very crude and shallow, being executed with the axe, but the chisel work of the later period is very fine, though often confined to the repetition of simple ornaments.

Norte (*Meteorol.*) *See* NORTHER.

North *or* **North-Seeking Pole** (*Elect.*) That pole of a magnet which tends to turn towards the north when the magnet is freely suspended.

Norther *or* **Norte** (*Meteorol.*) A cold dry north or north-west wind that occurs in the United States. In the southern parts it is called by this name, but in the north it is termed "blizzard."

——, **Black** (*Meteorol.*) A cold wind, so called by the Greeks.

Norwich Crag (*Geol.*) *See* CRAG.

Nose (*Glass Manufac.*) That end of the blowing iron upon which the molten glass is gathered.

Nosean (*Min.*) A sodium and aluminium silicate and sodium sulphate, $Na_4(NaSO_4 . Al)Al_2Si_3O_{12}$. Cubic; greyish or brown. It is of some interest as a rock forming mineral, occurring in some phonolites.

Nosing (*Build.*) The projecting edge of a moulding; the rounded projection of a window board, stair tread, etc.

Nosing Motion (*Cotton Spinning*). An attachment to the mule quadrant for determining the conical shape or chase of cop by regulating the speed at which the spun thread is wound round the spindle during winding on.

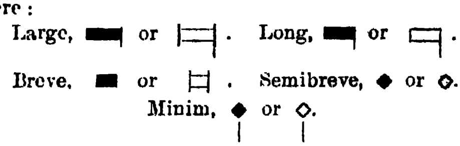
Notch Board (*Carp. and Joinery*). *See* CUT STRING.

—— (*Civil Eng., etc.*) A vertical barrier placed across a stream, and provided with a V-shaped notch through which the water flows. By measuring the breadth and depth of the part of the notch occupied by the water, the amount passing over in any given time may be found.

Notch Head (*Architect.*) *See* MASK.

Notching *or* **Linking Up** (*Eng.*) *See* LINK MOTION.

Notes (*Music*). Marks indicating sound. They are of different shapes, as follows:—Breve, 𝅜; semibreve, 𝅝; minim, 𝅗𝅥; crotchet, 𝅘𝅥; quaver, 𝅘𝅥𝅮; semiquaver, 𝅘𝅥𝅯; demisemiquaver, 𝅘𝅥𝅰; hemidemisemiquaver, 𝅘𝅥𝅱. Each of these is one half the value of the preceding note. In older music the notes were:



the Large being equal to four Breves or two Longs. This system of notation was formulated by Franco of Cologne, in the latter half of the eleventh century, according to one writer, and about 1200 according to another authority. *See also* PLAIN SONG.

—— (*Sound*). A note is, strictly speaking, a sound whose frequency of vibration, and therefore its pitch, are constant.

—— (*Typog.*) These are usually classed as: (*a*) footnotes; (*b*) marginal or side notes; (*c*) cut in notes; (*d*) shoulder notes. A footnote may be described as a passage explanatory of the text, and is set apart from it in a type two sizes smaller in body. Marginal notes, as their name implies, are placed on the margin of the page—usually outside and close to the reference in the text. Cut in notes are let into the square of the page, some of the lines of text being shortened for the purpose. These are generally placed on the folio side of the page. Shoulder notes refer to dates or volumes. Footnotes and, occasionally, marginal notes are indicated by reference marks, which are—the asterisk (*), the dagger (†), the double dagger (‡), the section (§), the parallel (‖) and the para-

graph (¶), used in the order here given. Two of each sign are used when the number of references exceed six. Another and older method is to use "superior" figures (1), (2), etc. Again, literal or letter references are used; these also are "superior," and may be either Roman or italic. When notes to a work are exceptionally numerous, or when for purposes of chronological sequence it is desirable to avoid division, they are sometimes placed under a distinctive heading at the end in the form of an addendum.

Nottingham White (*Dec.*) A term now nearly obsolete; formerly applied to a variety of reduced (*i.e.* adulterated) white lead.

Nourishing. *See* FAT LIQUORING.

Nova (*Astron.*) A new star.

Nowed (*Her.*) Knotted or twisted. Serpents are sometimes represented in this attitude as charges.

Noyau. A liqueur flavoured either with peach stones, oil of bitter almonds, the kernel of the Mahaleb cherry, or sometimes with essence of mirbane.

Nozzle (*Eng., etc.*) The jet or part of a pipe or tube containing the orifice.

N.P., *or* **New Par** (*Typog.*) Signifies commence a new paragraph. *See* PROOF CORRECTIONS.

Nucleic Acids (*Chem.*) White amorphous powders of unknown constitution; sparingly soluble in cold water, easily soluble in hot water; easily soluble in alkalis with which they form salts; their solutions are dextrorotatory; they unite with albumins. They are derived from the nucleo-proteids. *See* PROTEIDS. They yield on decomposition many important compounds of known composition, *viz.* (1) Phosphoric acid. (2) Pyrimidine derivatives. *See* PYRIMIDINES. (3) Purine bases. *See* PURINE. (4) Pentoses (*q.v.*) (5) Lævulinic acid (*q.v.*)

Nucleus (*Astron.*) A term used to express the innermost portion of a sun spot, comet, nebula, etc.

—— (*Botany and Zool.*) A protoplasmic body found in animal and plant cells. It is essential for carrying on the vital activities of the cell, and is especially concerned in cell division.

Nude (*Art*). A term applied to an undraped figure or statue; also to a study of the figure from the naked living model.

Null *or* **Zero Methods** (*Elect.*) A class of electrical measurements in which two quantities are compared by reducing one to equality with the other, the absence of any movement, deflection, etc., of the indicating instrument being taken as proof that such equality has been obtained. The measurement of resistance by Wheatstone's Bridge (*q.v.*) is an example of this method.

Numerals (*Typog.*) Letters or figures used for the purpose of indicating numbers. *Roman* numerals are represented by the letters I, V, X, L, C, D, M. I signifies one, V five, X ten, L fifty, C one hundred, D five hundred, M one thousand. These are placed in certain order to represent varying numbers, and are duplicated as necessary. When the lesser is placed before the greater, the lesser is deducted from the greater; thus, IV signifies one less than five, *i.e.* four. Lesser numbers placed after the greater are added. Capital, small capital, lower case, and italic letters are used in different circumstances. The *Arabic* numerals are expressed by the figures 1 to 0.

Nut (*Botany*). A one seeded, dry, indehiscent fruit, having a hard, woody coat and bearing persistent bracts, which in the oak (acorn) form a cup at the base of the nut. The Brazil "nut" is a woody seed; the cocoa- "nut" is a fibrous drupe.

—— (*Eng.*) The loose head of a bolt containing the hollow (or female) screw.

Nutation (*Astron.*) A slight motion of the pole of the Equator alternately towards and away from the pole of the ecliptic: a "nodding" of the pole. Has a period of nineteen years.

Nut Brown Colour (*Eng.*) The usual name for the brownish tint produced in tempering steel by heating it up to about 550° F. *See* TEMPERING.

Nutmeg (*Botany*). The nutmeg is the seed of the plant *Myristica fragrans* (order, *Myristicaceæ*), growing in the Moluccas, the islands of the Indian Ocean, the West Indies, etc. The fruit is prepared for export by drying over a slow fire. "Mace" is the bleached aril surrounding the seed.

Nut Oil. *See* WALNUT OIL.

Nutria (*Zool.*) The trade name for the fur of the coypu (*Myopotamus coypus*), an Argentine aquatic rodent. The skins of this animal are largely imported into Europe.

Nut Wrench (*Eng.*) A SPANNER (*q.v.*)

Nux Vomica (*Botany*). The dried seeds of *Strychnos nux vomica* (order, *Loganiaceæ*), a tree found throughout Southern and Eastern Asia and the north of Australia, notably in Ceylon. The extract and tincture are used in medicine.

Ω (*Elect.*) A symbol sometimes used for MEGOHM (*q.v.*)

ω (*Elect.*) A symbol for OHM (*q.v.*)

O (*Chem.*) The symbol for OXYGEN (*q.v.*)

—— (*Music*). Or.

Oak (*Botany*). Apart from its timber, the oak (*Quercus*, a genus of the order *Cupuliferæ*) yields many useful products. *Q. suber* provides the common cork, while the bark of *Q. robur* is used in tanning. *See also* VALONIA, QUERCITRON, *and* WOODS.

Oat (*Botany*). The cultivated cereal *Avena sativa* (order, *Gramineæ*) is probably a domesticated form of the wild oat (*A. fatua*).

Oatmeal (*Foods*). When the husks are removed from oats the grains are known as GROATS or GRITS, and these groats, when finely ground, constitute oatmeal. Oats rank second to wheat in point of nutrition, containing large amounts of proteid and fat, especially the latter. Oatmeal cannot be made into bread, owing to the absence of gluten; it is, however, made into thin cakes (oatcakes) by mixing into a paste with water, and then baking on an iron plate.

Obbligato (*Music*). A "necessary" part to a musical composition which cannot be dispensed with.

Obelisk. A column with a square base and rectangular in form. It diminishes in size towards the top, and usually terminates in a short pyramid. Egyptian obelisks are generally monoliths, *e.g.* Cleopatra's Needle on the Thames Embankment.

Oberon (*Astron.*) The outermost satellite of Uranus.

Oberwerke (*Music*). The German name for swell organ. *See* ORGAN *under* MUSICAL INSTRUMENTS.

Object Glass (*Light*). The lens in a telescope through which light enters the instrument; it produces a real image of the object viewed.

Objective (*Light*). In a microscope the lens or system of lenses through which the light enters the instrument; its function is to produce a real image of the object viewed. In an optical lantern the objective is the system of lenses which produces the magnified image of an illuminated slide (or other object) on the screen.

Objective Grating (*Astron.*) A diffraction grating placed before the object glass of a telescope for the observation of spectra.

Objective Prism (*Astron.*) A prism placed before the object glass of a telescope for the observation of spectra.

Oblateness (*Astron.*) The term applied to a form having more resemblance to an ellipse than a circle. The form of the Earth is characterised by its "ellipticity" or "oblateness."

Oblique Tenon (*Carp. and Join.*) The joint used when the pieces to be joined form an acute angle.

Obliquity of Connecting Rod (*Eng.*) The angle made by the connecting rod with the axis of the cylinder; it is greatest when the crank is at right angles to the rod. The obliquity affects the time at which the ports open and shut; it should be reduced as much as possible by using a long connecting rod.

Obliquity of the Ecliptic (*Astron.*) The angle between the ecliptic and the celestial equator. It is about $23\frac{1}{2}°$.

Oboe (*Music*). A reed stop on an organ. *See also* MUSICAL INSTRUMENTS—WIND.

Oboe d'Amour (*Music*). *See* MUSICAL INSTRUMENTS—WIND.

Oboe di Caccia (*Music*). *See* MUSICAL INSTRUMENTS—WIND.

—— *See* MUSICAL INSTRUMENTS—WIND (WOOD).

Obsidian (*Geol.*) The native glassy form of the volcanic rock known as Liparite, which is identical in chemical composition with granite. What is known as pumicestone is the same substance as obsidian, and owes its frothy condition to the fact that the fluid rock from which obsidian has cooled was heavily charged with steam and other gases, whose endeavours to escape have given rise to abundant cavities as the rock cooled.

Obtuse Angle. One greater than a right angle (90°).

Obverse (*Coins*). The side of a coin, medal, etc., on which the principal design, generally a head, appears. *Cf.* REVERSE.

Ocarina (*Music*). A terracotta instrument varying in size, and having finger holes pierced in the side. Its tone is rather sweet, but hollow.

Occlusion (*Chem.*) A name given by Graham originally to the property which platinum possesses of absorbing hydrogen when heated to redness in the gas, and of retaining it for an indefinite time at a lower temperature. Red-hot platinum absorbs 3·8 times its volume of hydrogen, and at 100° 0·76 times its volume. Palladium in the form of wire occludes 935 times its volume at a red heat, and 376 times its volume at the ordinary temperature. It increases in volume during the process. Copper, gold, silver, and iron all absorb small quantities of hydrogen. The state of the hydrogen when occluded by metals is uncertain; it has been suggested that it forms "unstable, easily dissociating compounds." Whatever its state, the hydrogen in palladium is capable of readily entering into reaction; it unites with oxygen to form water, reduces ferric and mercuric salts to "-ous" salts, and unites with iodine to form hydriodic acid.

Occultation (*Astron.*) The passage of the moon's disc across a star or planet.

Ochre (*Dec.*) A valuable group of natural pigments found in many parts of the world, and varying in colour from light to reddish brown yellow. The colouring matter is due to the presence of hydrous peroxide of iron, but analysis tells little as to the quality of ochres. Tone or colour is of great importance, as well as fineness of grinding. Crude ochres are prepared for painters' use by the process of levigation, after having been ground, if the hardness of the ochre renders this necessary. The pigment is dried at a low temperature, so as not to change the colour, and is then usually ground in oil. Sometimes the golden yellow ochres are "doctored" by the addition of a little chrome yellow.

Ochrea (*Botany*). The name given to the pair of coherent stipules forming a sheath round the stem, as in the dock family (*Polygonaceæ*).

Octagon. A plane rectilinear figure bounded by eight equal sides.

Octahedrite (*Min.*) A synonym for ANATASE (*q.v.*)

Octahedron. A solid bounded by eight planes; in a Regular Octahedron, the faces are equilateral triangles.

Octant. A SECTOR (*q.v.*) whose area is equal to one-eighth of the area of the circle; the radii bounding it make an angle of 45° with each other.

Octastyle (*Architect.*) A term used to denote a temple which has eight columns in the front row. *See* HEXASTYLE, PENTASTYLE, DISTYLE, *and* DECASTYLE.

Octave (*Music*). (1) The eighth note above, and bearing the same alphabetical name. It is the first of the harmonic series of sounds (*q.v.*), the vibrations being double the number of the octave beneath it. *See* INTERVALS. (2) Another name for the stop called "Principal" on organs. *See* ORGAN *under* MUSICAL INSTRUMENTS.

—— (*Sound*). The interval between two notes one of which has twice the frequency of the other.

Octave Flute *or* **Ottavino.** The name sometimes given to the piccolo.

Octavo (*Print.*) A leaf forming one-eighth of a sheet when folded for binding is said to be octavo size. The sheet thus makes 16 pages. Abbreviation, 8vo.

Octet (*Music*). A composition for eight voices or instruments.

Octodecimo (*Print.*) A leaf forming one-eighteenth of a sheet when folded for binding is said to be octodecimo in size. The sheet thus makes 36 pages. Abbreviation, 18mo.

Ocular (*Astron.*) *See* EYEPIECE.

Oculus (*Architect.*) (1) A large circular window in the centre of the west front of a church. This is a common feature in Continental churches, but is rarely met with in England. (2) A similar window or opening in the centre of a dome—as, for instance, the unglazed circular opening 27 in. diameter in the crown of the dome of the Pantheon at Rome.

Odeum (*Architect.*) A roofed building used by the ancient Greeks and Romans for musical performances. The name is sometimes applied to modern buildings used for similar purposes.

Odontograph (*Eng.*) A scale used in drawing the forms of the teeth of wheels.

Œnochoe (*Archæol.*) A small jug or vase, sometimes with a strainer in the neck, used for transferring the wine from the crater (*q.v.*) to the drinking-cup.

Œsophagus (*Zool.*) The œsophagus or gullet forms a straight tube leading from the pharynx to the stomach.

Off Cut (*Print.*) (1) The part of a sheet that is cut off to make it the proper size. (2) The part of a printed sheet cut off and folded separately for insertion in the larger portion, *e.g.* in the case of a duodecimo sheet.

Offensive Trades (*Hygiene*). The Public Health Act, 1875, sec. 112, specifies the following as offensive trades: Blood boiler, bone boiler, fellmonger, soap boiler, tallow melter, tripe boiler. The model byelaws of the Local Government Board specify, in addition to the above, the trades of blood drier, leather dresser, tanner, fat melter and extractor, glue maker, and size maker. The Public Health (London) Act, 1891, adds to these: manure manufacturer, knacker, and slaughterer of horses. As to what constitutes an offensive trade other than those specified, it is held that the business, in addition to being proved noxious, must be of the same nature as those specified, and must deal with animal matters in some form. Under penalty of a fine of £50, with a daily continuing penalty of £50, it is absolutely prohibited to establish anew in London the trade of blood boiler, bone boiler, manure manufacturer, soap boiler, tallow melter, or knacker; and without the consent of the London County Council, that of fellmonger, tripe boiler, or horse slaughterer. The business of soap boiling may be established anew with the sanction of the London County Council, provided that no animal oils or fats other than olein are used in the manufacture. The chief nuisances arise from the improper storage of the materials used and the offensive vapours given off during the process of manufacture.

Official (*Pharmacy*). Drugs are said to be "official" if they are included in the British Pharmacopœia, a list prepared and published by the General Medical Council acting under the authority of Parliament. A similar list is issued in most other countries. The name assigned to a substance in this list is its "official name."

Officinal (*Pharmacy*). The term applied to drugs kept and sold by druggists or apothecaries for medicinal use. *See* OFFICIAL.

Offing *or* Visible Horizon (*Astron.*) The bounding line of the portion of the earth visible to an observer whose eye is some distance above the surface. If R = radius of the earth, h the height of the eye above the surface, then the distance of the offing is (approximately) $\sqrt{\frac{2h}{R}}$

— **Distance of.** *See* OFFING.

Offset (*Botany*) A short stout shoot developed from the parent plant as a means of vegetative reproduction.

—— (*Build.*) A horizontal or inclined ledge, occurring at a change in thickness of a wall, buttress, etc.

Offset (*Elect. Eng.*) A subsidiary wire or cable leading from a main to a point where current is required.

—— (*Surveying*). A distance measured transversely from a point in a station line (usually at right angles to the latter) to some other point or object the position of which relative to the line is to be ascertained.

Ogee (*Architect.*) (1) A compound moulding formed by the conjunction of a cavetto and an ovolo. (2) A form of arch having each of its sides shaped similarly to a cyma-recta. The ogee arch was frequently used in the Decorated period of Gothic architecture. *See* CYMA.

Ogival (*Architect.*) A French term signifying Gothic. *See* OGIVE.

Ogive (*Architect.*) A French term used somewhat loosely, denoting the following: (1) A pointed arch. (2) A diagonal rib or arch of a Gothic vault. (3) An ogee (*q.v.*) *See* OGIVAL.

Ohm (*Elect.*) The practical unit of RESISTANCE (*q.v.*) It is equal to the resistance of a uniform column of mercury 106·3 cm. long and 14·4521 grams in weight at 0°C. For the purposes of legal definition it is the resistance of a certain standard coil at a temperature of 15·4°C.

Ohmic (*Elect.*) Due to, or relating to, RESISTANCE (*q.v.*) Thus OHMIC LOSS is the energy lost in a circuit through the resistance of the conductors.

Ohm Meter (*Elect. Eng.*) An instrument for the commercial measurement of resistance by a simple process.

Ohm's Law (*Elect.*) In any circuit the ratio of a uniform electromotive force to the current which it produces is a constant; this constant is termed the Resistance of the circuit. If C be the current, R the resistance, and E the electromotive force, then C is proportional to $\frac{E}{R}$. If the current be in ampères, the resistance in ohms, and the electromotive force in volts, then $C = \frac{E}{R}$.

Oil Coil (*Elect.*) (1) A transformer which is oil cooled. (2) A TESLA COIL (*q.v.*)

Oil Cooling (*Elect. Eng.*) Enclosing a transformer in a bath or tank containing oil, in order to aid the dissipation of heat due to the currents.

Oiled Paper (*Paper Manufac.*) The paper used for copying books consists of ordinary paper brushed over with boiled linseed oil.

Oil Engine. An engine in which the source of energy is the combustion within the cylinder of a gaseous charge, derived from the vaporisation of a suitable oil. Strictly speaking, this definition includes all the types of engine used in motor cars, cycles, and boats; but it is convenient to make a distinction between those engines using a very volatile oil (petrol, motor spirit, etc.) and those using a heavy oil, such as ordinary Petroleum. To the latter class the term Oil Engine is most commonly applied. The design commonly follows that of a Gas Engine (*q.v.*), with the addition of a tank or reservoir to contain a supply of oil; a Vaporiser or Carburetter, by which the oil is converted into vapour, and the necessary pumps, valves, and tubes by which the supply of oil to the vaporiser is maintained. Oil Engines of modern type differ

chiefly in the nature of the vaporising arrangements, and are usually divided into four main classes: I. The explosive mixture is formed in a large chamber, into which the oil is injected by a spraying nozzle. The vapour mixes with the whole of the air necessary for combustion while in this chamber, and the mixture is drawn into the cylinder as required. The chief objection to this type is the presence of a large volume of explosive gas in the vaporiser. II. The oil is vaporised in a small chamber along with a little air; the remainder of the air required for combustion enters the cylinder through a separate valve. III. The oil is vaporised in a small chamber, through which the whole air supply is also drawn. IV. The oil is vaporised in the combustion chamber itself, which is an extension of the cylinder; air enters through a separate valve. In order to start the engine, the combustion chamber is heated by a lamp; when the engine is running, the necessary temperature is maintained by the explosions. The Hornsby Ackroyd engine is typical of Class IV. A suitable quantity of oil is forced into the combustion chamber and rapidly vaporised; owing to the absence of fresh air, the vapour does not ignite at this stage. The forward stroke of the piston then draws in a supply of air; the return stroke compresses the mixture, raising its temperature by the compression, and ignition occurs spontaneously, just as the piston commences the next forward stroke. The timing of the ignition is effected by varying the amount of compression, *i.e.* by altering the volume of the clearance space. Thus no ignition tube, sparking plug, or other special device for firing the charge is required. The governing of the engine is effected by regulating the supply of oil which enters the combustion chamber. An oil engine requires no permanent supply of gas and no fixed pipes or connections: its fuel is cheap and portable, and the engine can be set up in places where gas is unobtainable and coal is scarce or difficult to transport. Extensive trials have shown that the consumption of oil in a good engine may be as low as ·75 lb. per indicated horse power hour.

Oil Feed (*Eng., etc.*) Any apparatus used for supplying oil regularly to a moving part of a machine.

Oil Fuel (*Eng.*) The methods of using oil as fuel or the source of energy may be divided as follows: I. INTERNAL COMBUSTION: The oil is vaporised and forms an explosive mixture in the cylinder of an engine, as described under OIL ENGINE and PETROL ENGINE (*q.v.*) II. EXTERNAL COMBUSTION: The oil is burnt in the firebox or furnace of a boiler in order to generate steam. The oil may be vaporised in a separate chamber, and burnt with a suitable air supply at the mouth of a large burner; this method is used in the boilers of steam motor cars and certain other small boilers. In larger boilers, the oil is sprayed direct into the firebox along with an air supply, sometimes supplemented by a jet of steam. The firebox should be provided with either a lining or a bridge of firebrick, to prevent the flame from playing directly on the metal surfaces. The great advantages of oil fuel are the reduction of space for storage, saving of labour in handling the fuel and in stoking, rapidity with which steam can be got up, and the ease with which the rate of combustion can be controlled. It is thus very suitable for use in steam vessels, especially battleships. Oil fuel used for external combustion is, however, dearer than coal.

Oil Hardening (*Eng.*) Steel is sometimes hardened by heating to redness and plunging into oil; this cools it less rapidly than water would do, the result being that it is less brittle.

Oiling (*Woollen Manufac.*) The application of oil to wool prior to blending and carding. This causes the fibres to glide very readily over each other and to be easier of separation, and yet imparts an artificial degree of adhesiveness.

Oiling Motion (*Woollen Manufac.*) A mechanical method of oiling the wool as it passes over the feed sheet of the Fearnought or the Teazer. It sprinkles the wool with a regular quantity of the oiling composition.

Oil of Mustard (*Chem.*) *See* MUSTARD OILS.

Oil of Turpentine (*Dec.*) *See* TURPENTINE.

Oil of Vitriol (*Chem.*) A common name for sulphuric acid (*q.v.*) *See* SULPHURIC ACID.

Oil Paint (*Dec.*) Paint mixed with oil, usually linseed, in contradistinction to water paints and distemper, in which water is employed as a vehicle instead of oil.

Oil Painting. *See* PAINTING (METHODS) *and* HOUSE PAINTING.

Oil Pump (*Eng.*) A small pump either driven by hand or working automatically; used to force oil into bearings or other moving parts of machinery.

Oils. Oils and fats are obtained from nearly every subdivision of the vegetable and animal kingdoms, while the earth yields a very similar product in so-called mineral oil (*see* PETROLEUM), which was doubtless, originally, of organic origin. No precise classification of oils is possible, and the plan usually followed is to arrange them according to the properties they possess; for instance, vegetable oils being divided into drying, semi-drying, and non-drying oils. The animal oils are more usually divided according to their source of production, viz. fish oils, liver oils, and blubber oils, beef and mutton tallows, bone fat, horse fat, etc. A further classification deals with the oils according to their particular uses and the treatment necessary to fit them for the purpose in view. The difference between an oil and a fat depends only upon temperature; thus butter, which is considered a fat in this country, might also be classified as an oil in a very hot climate. Nearly all vegetable oils are extracted from the seed, either by (*a*) expression or (*b*) volatile solvents. Linseed oil is the vegetable oil which is most largely produced in this country, the value of the linseed or flax seed imported in one year amounting in round figures to £4,500,000 in value. The value of cotton seed imported amounts to nearly £3,500,000, and the quantity is increasing.

Although the treatment of the oil seeds and the machinery employed varies with the particular kind of seed to be treated, the operations are in many respects similar. LINSEED is now usually taken up from barges or vessels brought alongside the wharves to the top of the mill by means of portable elevators or suction pipes. Here it is conveyed to any part of the building by means of travelling bands and a series of shoots leading from floor to floor, and is ultimately conveyed to the milling room, which is usually on the ground floor. The seed as received from abroad is often mixed with various other seeds, stones, dust, and foreign material. When a better

class oil is required the linseed, before reaching the milling room, is passed through a cleaning machine worked in conjunction with a fan, by which means dust and foreign seeds are extracted. Magnets are sometimes used in addition to take out nails and pieces of metal which may have accidentally become mixed with the seed. The first operation in the milling room is to grind the seeds into meal in an edge runner, or between rollers of an Anglo-American five roller machine. It is then usually conveyed to a kettle, heated by steam and partly cooked, this having the effect of increasing the yield of oil, or rather of rendering it more fluid and easy to extract. Beneath the kettle is a measuring box, which, when full, is drawn out, the meal dropping on to a press cloth and being then lightly pressed, so that it may be taken out in a fairly solid form for conveyance to the hydraulic press. The solid cake of meal, with the press cloth, is then placed between two iron plates, and further cakes and plates are built up to the extent of usually about sixteen. Each plate is engraved with the name or device of the manufacturers. The hydraulic press having been started, the oil is gradually pressed out, and runs off into a tank below, whence it is afterwards pumped to the refinery, or in some cases sent to a firm who make a business of refining. The cake or residue of the linseed, while still warm, is trimmed in a special paring machine, and forms valuable feeding stuff for cattle, owing to the oil contained in it. In some cases where the residual cake is not to be used, such as in the case of castor oil seeds, a second pressing is given, the first cake being broken or ground up for the purpose. The process described is substantially that followed in the case of most seeds. The recovery of oil by means of solvents is carried on principally in connection with rape seed and castor seed; the solvent used is usually petroleum ether or carbon bisulphide. Two types of apparatus are in use, one termed the "cold" process, and the other the "hot." In the former a series of vessels are so arranged that the solvent percolates from end to end in such a manner that the particular vessel which receives the refuse meal that has been acted upon is the one which, when emptied, is ready to be recharged. The mixture of oil and solvent being withdrawn, the latter is driven off by means of heat, the vapour being condensed in a coil so that it may be used over and over again. The hot process is objectionable from the risk of fire. Linseed oil is the principal PAINT OIL (*q.v.*) The preparation of COTTON SEED OIL is in many respects similar to that of linseed oil; the cotton husks being expressed, the product is used very largely for food. It is estimated that 9,000,000 gallons are employed in one year for making compound lard. OLIVE OIL is obtained from the fruit of olives after the kernels have been removed. In the best grades the fruit when ripe is picked by hand, usually in the months of October and November. The fruit is crushed, and the pulp placed in rush baskets with a small opening at the top. These baskets are placed one on top of the other in a press worked by hand. The oil is thus expressed, and runs into a vessel below, which is partly filled with water, in order that the impurities contained in the oil may be deposited and the oil collect on the surface. The pulp is subsequently crushed several times, thus giving various grades of oil, of which there are a large number, depending not only upon the method of preparation, but also on the degree of ripeness of the fruit, the variety of the tree from which the olives are obtained, and other circumstances. Olive oil is chiefly employed for alimental purposes; the inferior qualities are frequently employed for soapmaking, and also as lubricants (*q.v.*) Olive oil is often adulterated with cotton seed oil and oil from various vegetable sources. The specific gravity of olive oil at 15° C. is 0·9178; this is for best or virgin oil; that of Gallipoli oil is 0·9196.

DRYING OILS are those which, when exposed to the air, combine with oxygen and become hard. Non-drying oils when so exposed do not dry, but become rancid, and in many cases undergo decomposition. The principal drying oils, in addition to linseed oil, are the oils derived from hemp seed, poppy seed, walnuts, castor seed, sunflower seed and grape seed. There are many other drying oils, such as garden cress seed oil, hickory oil, melon seed oil, pumpkin seed oil, which are not regarded as commercial products. HEMP SEED OIL is sometimes used in the manufacture of colours and varnishes, being then usually mixed with linseed oil. It is also employed for the same uses as olive oil. POPPY SEED OIL is somewhat important, because of its light colour. It is largely employed abroad for grinding white paints such as zinc oxide, the absence of colour being valued where it is desired to maintain the purity of tint. Poppy oil in this country is chiefly used for artists' colours; walnut oil is also used for artists' colours. *See also* WALNUT OIL, CASTOR OIL, POPPY SEED OIL.

The principal NON-DRYING VEGETABLE OILS are cotton seed oil (*q.v.*), ground nut oil (arachis), hazel nut oil, maize oil, almond oil, palm oil, cocoanut oil, and olive oil. The following oils are also produced in various parts of the world in more or less large quantities: plum kernel oil, sesame oil, mustard oil, horse chestnut oil, peach oil, quince oil, radish seed oil, rice oil, cherry kernel oil, linden wood oil, tea seed oil, beech nut oil, acorn oil, and croton oil.

ANIMAL FATS and oils are produced in very large quantities in a variety of different ways, having for their object the same end as in the case of vegetable oils, namely, the separation of the oil from the extraneous material. In many cases the process consists principally of boiling in closed vessels, and drawing off the oil so obtained. The animal kingdom contains oil almost universally, and very little of it is wasted. The most familiar example of the production of fat or tallow from freshly killed cattle and sheep is done in each of the large towns, usually by the biggest firms of soapmakers, who collect the waste fat at frequent intervals, and in some cases have offices and depôts established in connection with the meat markets or slaughtering houses. In such cases the scrap fat is boiled down the same day as it is collected, and in this case it is usually sold to margarine makers or the manufacturers of butter substitutes, and is often used mixed with a preparation of cotton oil. Animal fat being the chief raw material used by such makers, the business of recovering and rendering fat is usually carried on in connection with soapmaking business. Perhaps the most important animal fat is tallow, which is divided into two definite classes, beef tallow and mutton tallow. The quality depends not only upon the part of the animal from which the fat is derived, but also the manner in which the animal has been fed. *See* TALLOW.

LARD is obtained from the fat of the kidneys and intestines of the hog, together with that portion lying beneath the skin. The quality varies according

to the part of the animal the fat is obtained from. Where lard is prepared on a large scale the different parts are rendered separately, thus giving definite qualities. For instance, in the American market, whence comes much of the lard that reaches this market from abroad, the term "Neutral Lard No. 1" is applied to the fat which is obtained from the interior of the pig rendered while perfectly fresh. It is used almost exclusively by margarine manufacfacturers. "Neutral Lard No. 2" is another grade which is chiefly used by confectioners, and there are various other grades. The method of preparing is to carefully melt the raw material, which is first freed as far as possible from flesh, sinews, and skin, and is then cut into small pieces by means of a machine. The melting pan is often steam jacketed, and the fat is stirred by wooden paddles while being extracted until it is quite white. It is strained before being placed in cooling vessels, and again stirred while it is actually cooling, although it is important to suspend the operation before the mass gets solid. The specific gravity of lard at 15° C. is 0·931. Lard oil is obtained from lard by pressure. It is somewhat similar to olive oil in appearance, and is valuable for lubricating purposes. The solid portion of the tallow left behind in the presses is useful for candle manufacture. HORSE FAT is used in leather manufacture for lubricating and for the manufacture of soft soaps. BONE OIL and BONE FAT are important products, and are obtained from the bone marrow and also from the bone itself. In the manufacture of glue, gelatines, and size the process includes the preparation of considerable quantities of bone fat. The extraction of the oil is either done by boiling, steaming, or extraction by a solvent.

The FISH OILS obtained from the livers of various animals are of considerable commercial importance, particularly cod liver oil, which is largely used in currying leathers as well as for medicinal purposes. Shark liver oil is also produced to a considerable extent. Whale oils are obtained from several animals, in addition to the Greenland whale, such, for instance, as the seal, walrus, sperm whale, porpoise. Seal oil is of various grades (*see* SEAL OIL), and among fish oils there are those obtained from the herring, pilchard, sardine, salmon, sprat, and other fishes. As indicating the very wide field from which oils and fats are derived, a few of the animals and vegetables from which they are obtained, in addition to those already mentioned, may be given: apricot, badger, belladonna seed, brazil nut, candle nut, chamois, chicken, cress seed, cucumber seed, dog, domestic duck, gingelly, goose, hare, honesty, horse-chestnut, laurel, Niger seed, nutmeg, palm, reindeer, roebuck, Scotch fir seed, spruce fir seed, sunflower, seakale, thistle, wild goose, wild rabbit.

The most interesting oils at this time are, perhaps, MAIZE OIL and TUNG OIL (*q.v.*), or Chinese wood oil, which bid fair to increase considerably in use.

A. S. J.

Oils, Chemistry of. The term "oil" is not capable of exact definition, as it is applied to substances of widely different classes. Three classes of oils may be distinguished: (1) BURNING AND LUBRICATING OILS: These are usually composed of PARAFFINS (*q.v.*), OLEFINES (*q.v.*), and NAPHTHENES (*q.v.*) These occur naturally in the earth. (2) FIXED OILS: Oils which cannot be distilled (at any rate under ordinary atmospheric pressure) without decomposition. They are usually obtained from animals and from the fruits and seeds of plants, and chemically they are glycerine esters of saturated (butyric and higher) and unsaturated (oleic, etc.) acids of the fatty series. (3) ESSENTIAL OR VOLATILE OILS: As the name implies, they are volatile; that is, they distil unchanged at the ordinary pressure, and most of them distil in steam. They are obtained from plants, some from roots, some from stems, some from leaves, some from fruit, and usually by distilling with steam; but some, like oil of lemon, by pressure. They have distinctive odours, and are used in many ways, as in perfumery, medicine, mixing paints. They belong to widely different classes of chemical compounds, *e.g.* hydrocarbons. *See* TERPENES. *Alcohols and Phenols:* Oil of cloves contains eugenol (*q.v.*); oil of peppermint contains menthol (*q.v.*); oil of lavender contains linalool (*q.v.*) *Aldehydes:* Oil of cinnamon contains cinnamic aldehyde; oil of bitter almonds contains benzaldehyde (*q.v.*) *Ketones:* Examples of these will be found under TERPENES, where they are mentioned incidentally. *Esters:* Oil of wintergreen is methyl salicylate; oil of limes, neroli oil; jasmin oil and others contain linalyl acetate. Oils are colourless or yellow liquids, insoluble in water, except some of the essential oils, which dissolve enough to give an odour to the water. They are rarely pure or even nearly pure substances, but oil of wintergreen is nearly pure methyl salicylate; every other oil mentioned above is a mixture of substances.—W. H. H.

Oil Shales (*Geol.*) Argillaceous rocks of sedimentary origin which contain diffused hydrocarbons in a state which admits of their being distilled into paraffin oil on the proper application of heat. The term is properly restricted to those rocks of this class which contain the hydrocarbons in quantities sufficient to leave a profit after all the working and other expenses have been paid. Oil shales occur in thin beds like coal seams, and are finely laminated. They are generally sooty brown in colour, which becomes paler in the powder, resulting from a scratch or a streak. The rock is about as hard as biscuit, and therefore easily cut with a knife, which leaves a shining mark, having a lustre nearly like that of cut wax. Thin sheets of oil shale are elastic. This elasticity is dependent, like the degree of waxiness of the cut surface, upon the percentage of hydrocarbon present, of which these characters form a rough test. Oil shales graduate vertically and also laterally into ordinary shales, and are commonly interstratified with rocks of this type to an indefinite extent. The Scottish oil shales are confined to geological horizons near the middle of the Lower Carboniferous Rocks, and are practically limited in their geographical distribution, even on these horizons, to parts of Mid and West Lothian. Rocks of similar character occur sparingly in other geological formations in Britain, of which the chief is in the Kimeridge Clay of the south of England. This and various other impure oil shales have occasionally been used in the furnaces of steamboats in lieu of coal. There are reasons for believing that oil shales have been formed in lagoons, in which solutions of sulphate of lime more or less concentrated by evaporation have further decomposed macerated vegetable matters and converted part of the products into gummy compounds which have diffused through the argillaceous sediments at the bottom of the lagoon. The geological evidence lends but little support to the old view that the hydrocarbon was

due to the distillation of coal seams by the heat connected with the intrusion of eruptive rocks.—J. G. G.

Oil Stone (*Carp., Eng., etc.*) A flat stone of fine grain, used for setting or finishing the cutting edge of tools. Many oil stones consist of some kind of slate. The best known forms are the Turkey, Charley Forest, Arkansas, and Washita.

Oil Varnishes (*Dec.*) The group of varnishes made from linseed oil and gums, and used by house and carriage painters, etc., as distinguished from turpentine, water-, and spirit-varnishes. *See* VARNISHES.

Old English (*Typog.*) A comprehensive term applied to most types of the Black letter order, including those used in the fifteenth century and the more modern varieties.

Old Face (*Typog.*) A name given to a robust form of Roman types originally used by the early Flemish printers, and of which the Elzevirs are examples; they were subsequently copied by William Caslon. The letters are somewhat rude, but strong in form and without violent contrasts between the thick and thin lines. The term is generally used to distinguish founts of this character from the lighter and more elegant "Old Style."

Double Pica Old Face.	Typography.
Double Pica Old Style.	Typography.

Old Fustic. *See* DYES AND DYEING.

Old Man (*Mining*). A term applied to former and unknown workers in a mine.

Old Red Sandstone (*Geol.*) A general name for an important group of Deuterozoic formations which were laid down under continental conditions during the Devonian Period. Taking them as a whole, the rocks are characterised by a red coloration; and on some horizons the strata consist of sandstones. At the top is the Upper Old Red Sandstone, which heralds the Carboniferous Period. The Upper Old Red lies with an unconformity representing an hiatus of several miles upon all the rocks older than itself. The highest member of the next below is the Orcadian or Middle Old Red Sandstone, which was preceded in time by the Caledonian Old Red, which, again, lies with a violent unconformity upon the uppermost Silurian rocks, and all the rocks older than that.

Old Sand (*Foundry*). The sand forming the floor of a foundry; it is used for the parts of a mould which do not come into contact with the casting.

Old Style (*Typog.*) The designation of (1) a nineteenth century Roman type of light and elegant face, with a tendency to very fine lines in the upright strokes and serifs. *See* OLD FACE. (2) A style of arrangement in bookwork and display in jobbing composition.

Old Woman's Tooth (*Join.*) A ROUTER or plane for levelling the surface of grooves, etc., which lie below the general level of the surface of woodwork. The plane iron is narrow, and its cutting edge projects below the bottom or sole of the plane by an amount equal to the depth of the groove which is being cut.

Oleaceæ (*Botany*). A dicotyledon natural order found in tropical and temperate climates. It includes economic plants such as the olive and ash.

Olefiant Gas (*Chem.*) *See* ETHYLENE.

Olefines (*Chem.*) An olefine is a hydrocarbon containing n carbon atoms united in an open chain, and $2n$ hydrogen atoms in its molecule; n may be any whole number from 2 upwards. As n carbon atoms united in an open chain can unite with $(2n + 2)$ hydrogen atoms at the most, the olefines are said to be unsaturated. This state of unsaturation is conventionally represented by a double line joining the two carbon atoms having the deficiency in hydrogen, for it is found by experience that the unsaturation consists always in two adjacent carbon atoms, each having one hydrogen atom less in any given olefine than the same two carbon atoms have in the corresponding paraffin hydrocarbon into which it can always be converted. Examples of olefines:

Ethylene .	$CH_2 = CH_2$
Propylene .	$CH_2 = CH - CH_3$
Butylene .	$CH_2 = CH - CH_2 - CH_3$
Pentene .	$CH_2 = CH - CH_2 - CH_2 - CH_3$

It is clear that the compound $CH_3-CH=CH-CH_3$ is isomeric with butylene; it may be called butene-2 (*see* NOMENCLATURE) or symmetrical dimethyl-ethylene; it is sometimes called pseudo-butylene. It is an interesting substance because it exhibits another form of isomerism. *See* STEREOISOMERISM. Position isomerism can occur with the olefines just as it does with the paraffins (*q.v.*) Example:

Butylene . . . . $CH_2=CH-CH_2-CH_3$

Isobutylene (Methyl-2-propene), $CH_2 = C\begin{smallmatrix} CH_3 \\ CH_3 \end{smallmatrix}$

On account of their unsaturated character the olefines show many additive reactions: (1) They unite with hydrogen in presence of finely divided platinum or nickel to form the corresponding paraffins:

$$\begin{array}{c} CH_2 \\ \| \\ CH_2 \end{array} + H_2 = \begin{array}{c} CH_3 \\ | \\ CH_3 \end{array}$$

(2) They unite with halogens directly, *e.g.* ethylene gives ethylene dibromide:

$$CH_2Br$$

(3) They unite with hydriodic, hydrobromic, and sulphuric acids directly on heating; the negative part of the acid molecule attaches itself to the carbon atom containing the least hydrogen, *e.g.*

$$\begin{array}{c} CH_2 \\ \\ CH_2 \end{array} \text{ gives } \begin{array}{c} CH_3 \\ | \\ CH_2I \end{array} \qquad \begin{array}{c} CH_3 \\ | \\ CH \\ \\ CH_2 \end{array} \text{ gives } \begin{array}{c} CH_3 \\ | \\ CH.HSO_4 \\ | \\ CH_3 \end{array}$$

Ethyliodide.

(4) They unite with hypochlorous acid to form chlorhydrins:

$$\begin{array}{c} CH_2 \\ \| \\ CH_2 \end{array} \text{ gives } \begin{array}{c} CH_2Cl \\ | \\ CH_2OH \end{array} \qquad \begin{array}{c} CH_3 \\ | \\ CH \\ \| \\ CH_2 \end{array} \text{ gives } \begin{array}{c} CH_3 \\ | \\ CHCl \\ | \\ CH_2OH \end{array}$$

(5) On gentle oxidation they yield glycols (*q.v.*), but on strong oxidation they break down at the double linking, *e.g.* propylene strongly oxidised gives acetic and formic acids. (6) Most olefines undergo polymerisation. The olefines occur to some extent with the paraffins in crude petroleum; and ethylene forms the principal illuminant in coal gas. They are

obtained in many ways. A few are: (1) Heating a paraffin alcohol with sulphuric acid:

$$\begin{array}{l} CH_3 \\ | \\ CH_2OH \end{array} + H_2SO_4 = \begin{array}{l} CH_3 \\ | \\ CH_2HSO_4 \end{array} + H_2O$$

Ethylhydrogen Sulphate.

$$\begin{array}{l} CH_3 \\ | \\ CH_2HSO_4 \end{array} = \begin{array}{l} CH_2 \\ \| \\ CH_2 \end{array} + H_2SO_4$$

(2) From monohalogen substituted paraffins by heating with alcoholic potash:

$$\begin{array}{l} CH_3 \\ | \\ CH_2I \end{array} + KOH = \begin{array}{l} CH_2 \\ \| \\ CH_2 \end{array} + KI + H_2O$$

Ethyliodide.

(3) Electrolysis of a solution of the potassium salt of succinic acid and its homologues:

$$\begin{array}{l} CH_2COOK \\ | \\ CH_2COOK \end{array} \text{ gives } \begin{array}{l} CH_2 \\ \| \\ CH_2 \end{array}$$

Pot. Succinate.

Oleic Acid (*Chem.*) $\begin{array}{l} C_8H_{17}.C.H \\ \qquad \| \\ H.C.(CH_2)_7COOH. \end{array}$

A colourless liquid; no taste or smell; melts at 14°; boils at 223° under a pressure of 10 mm. of mercury; insoluble in water, but easily in usual organic solvents. Turns yellow, then brown, on exposure to light and air. Hydriodic acid converts it into stearic acid; it is also changed to stearic acid by heating with hydrogen in contact with finely divided nickel spread on pumice stone. Nitrous acid changes it to the stereoisomer elaidic acid (*q.v.*); it adds bromine, and is oxidised by potassium permanganate like the olefines (*q.v.*) It occurs as its glycerine ester, TRIOLEIN, in a large number of oils and fats; *e.g.* olive oil, cod liver oil, lard, goose fat, etc. To obtain the pure acid, olive oil is boiled with caustic potash solution; the liquid is treated with lead acetate, forming the lead salts of the acids; the precipitated lead salts are dried and extracted with ether, which dissolves lead oleate; the lead is precipitated with hydrochloric acid, and the ethereal solution of oleic acid is filtered off and evaporated. The pure acid is obtained by fractional distillation of the residue from the ether in a vacuum. Oleic acid forms many salts, of which the lead salt is the most important, because it is the chief constituent of lead plaster. *See also* IODINE ABSORPTION.

Oleograph. A picture or a reproduction of a picture printed in oil colours: a chromolithograph.

Oleo-Margarine (*Foods*). The term applied in the United States to margarine (*q.v.*)

Oligocene (*Geol.*) A name now much used for the subdivision of the Tertiary Rocks in which a *few* living species of marine mollusca, as compared with the extinct species, are to be found. The formation is of much importance on the Continent, but in Britain is represented only by a small thickness of strata of fluvio-marine origin in the Isle of Wight.

Oligoclase (*Min.*) An aluminium sodium and calcium polysilicate; one of the Felspars corresponding to a mixture of three parts of Albite to one of Anorthite. Triclinic. Usually greyish or yellowish. From Scandinavia and many places in America.

Olive (*Botany*). The fruit of *Olea europæa* (order, *Oleaceæ*) is valued for the oil which it yields and as a comestible when pickled in an unripe state. It is much cultivated in Mediterranean countries, as well as in other suitable regions.

Olive Oil. *See* OILS.

Oliver (*Eng.*) A primitive form of mechanical hammer used by blacksmiths; it is now obsolete.

Olivine (*Min.*) A synonym for CHRYSOLITE (*q.v.*)

Olla (*Pot.*) (1) An earthenware pot used by Spanish peoples for cooking and other purposes. (2) The mess of meat and vegetables cooked in such a utensil. (3) A porous jar for keeping drinking water cool.

Ombrometer (*Meteorol.*) An instrument for recording automatically the time, quantity, etc., of a rainfall. *See also* RAIN GAUGE.

Omnibus Bars (*Elect. Eng.*) Heavy conducting bars in an electric generating station, to which the terminals of the dynamos are attached.

Once Marked Octave (*Music*). The seven notes commencing with middle C (*q.v.*) In organ nomenclature the once marked octave is an octave higher than the above. *See also* PITCH.

One-at-Once Wheel, One-at-Once Engine (*Lace Manufac.*) Hand and power machine respectively for conducting the process of One-at-Once Winding.

One-at-Once Winding (*Lace Manufac.*) A system by which the brass bobbins are wound, one at a time, upon a spindle revolving at a great speed. By this system the end from the fresh source of supply is simply tied to the end of whatever may be upon the bobbin and the bobbin filled up.

One Coil Transformer (*Elect. Eng.*) An AUTO TRANSFORMER. *See* TRANSFORMER.

Onyx (*Min.*) A variety of CHALCEDONY (*q.v.*) showing parallel banding. The bands are of different absorptive power, and advantage is taken of this to make some bands take up a solution of sugar; on treatment with sulphuric acid the sugar is charred, and thus the black and white banding of the jeweller's onyx is produced.

Oolite (*Geol.*) A rock formed of small spheroidal pellets of carbonate of lime, and which bears some resemblance to the "hard roe" of a fish. The structure of each pellet resembles that of an onion, as it is built up of concentric coats. These severally show a fibrous structure radiating from the centre of the pellet. The core of the pellet, in the case of typical oolite, usually consists of a fragment of some other body. Oolitic structure may arise in various ways; but, in the typical oolites, the pellets have been formed by the organic agency of an alga. In some other cases they are due to organico-chemical agency, as in the Carlsbad "Sprudelstein." Large grained oolite is often distinguished from the normal type as Pisolite. Oolitic structure occurs chiefly in the limestones of Jurassic age; but it is by no means uncommon in rocks older or newer in the geological series.

Op. (*Music*). The abbreviation of *opus* (work), a form of numbering musical compositions in order of publication. An opus may consist of one or more numbers.

Opal (*Min.*) Hydrous silica in an amorphous form. The amount of water varies. Many varieties show beautiful internal colours and are used as gems. Such come from Hungary and Australia. The common varieties are usually milky white to yellow and brown, with a resinous lustre. Some are opaque and dark coloured.

Opalite (*Build.*) A glazed substance about ⅛ in. thick, fixed on the surface of walls to represent glazed brickwork.

Opal Plates (*Photo.*) A porcelain or glass plate with an opaque white glaze, coated with a sensitive film similar to those used on bromide printing papers; used for making positive prints.

Opaque (*Paint.*, *etc.*) The term applied to a pigment or substance that is impermeable to light and which is therefore not transparent. *See* BODY.

Open Belt (*Eng.*) A driving belt which is not crossed.

Open Chain Compounds (*Chem.*) When two or more carbon atoms are united in a compound they are said to form a chain. When there are three or more carbon atoms united together, two possibilities present themselves with regard to the carbon atoms at the ends of the chain: (1) They may be united; (2) they may not be united. In the latter case we have an open chain compound. Examples:

$$CH_2 = CH - CH_3 \qquad H_2C \overset{CH_2}{\angle \!\!-\!\!-\!\!\diagdown} CH_2.$$

Open Chain. Closed Chain.

Open Circuit (*Elect.*) An interrupted or broken circuit.

Open Coil Armature (*Elect. Eng.*) An armature whose coils do not form part of a closed or complete circuit during the whole of each revolution.

Open Diapason (*Music*). A stop having no plug in the top of the pipes found on both the pedals and manuals of an organ (*q.v.*)

Open Hearth Processes (*Met.*) Processes for the production of steel from pig iron in reverberatory furnaces, as distinguished from the Cementation or the Bessemer Process. In this system pig iron is mixed with wrought iron, steel scrap, or with iron ores rich in oxides. *See* STEEL, SIEMEN'S PROCESS, METALLURGY, *and* FURNACES.

Opening (*Cotton Manufac.*) The first process in cleaning cotton. The fibres are separated or opened out by getting a thorough shaking, thus freeing the pure cotton from dirt, seed, broken leaf, and other foreign substances. The chief forms of openers are (1) CREIGHTON, (2) PORCUPINE, (3) MODIFIED WILLOW, to which may be attached a hopper feeder if necessary.

—— (*Typog.*) When newspaper copy is given out in small portions it occasionally happens that one of the pieces is in hand longer than the others. If a gap is thereby caused, the compositor who is behindhand is said to be in the "opening."

Open Joint (*Patternmaking*). The wide parts of large patterns are often made of a number of pieces of wood, separated by narrow spaces to allow for expansion of the wood without producing distortion when the moisture of the mould acts on the pattern.

Open Mouth (*Eng.*) A punching or shearing machine in which the jaws are formed like a letter C, allowing the edge of a wide plate to be inserted.

Open Notes (*Music*). The notes given (1) by the open strings of musical stringed instruments; (2) by wind instruments when neither slide nor piston nor hand is used. *See* VIOLIN, HORN, TROMBONE, *under* MUSICAL INSTRUMENTS.

Open Pattern (*Eng.*) A pattern which only produces the main outline or contour of the required casting in the sand, leaving the rest of the mould to be finished by hand. Also termed a SKELETON PATTERN.

Open Pig (*Met.*) Soft cast iron pigs having a loose crystalline structure.

Open Sand (*Foundry*). Castings made in a mould whose top is open to the air are said to be made in "open sand."

Open Scale (*Phys.*, *etc.*) A scale is said to be open when its divisions are fairly wide apart, *e.g.* the term is applied to thermometers with wide spaces between the marks which denote degrees.

Open Score (*Music*). A score having but one part written on each stave. *See also* SCORE.

Open Shed, Open Shedding (*Weaving*). Applied to shedding motions, *e.g.* tappets, dobbies, Jacquards. The system of shedding the heddles or heald shafts by which any particular group of shafts may be retained in the upper or lower position for any required number of picks. It is the opposite in principle to the CLOSED SHED (*q.v.*)

Open Space (*Hygiene*). The Model Byelaws provide that a new house must have along its whole frontage an open space measuring at least 24 ft. to the boundary of any land or premises immediately opposite. In the rear there must be an open space, exclusively belonging to the house, at least 150 superficial feet in area and free from any erection above the ground level, except a closet and an ashpit. It must extend along the entire width of the house, and must measure in no case less than 10 ft. from every part of the back wall of the house. If the house be 15 ft. high, the distance must be 15 ft.; if 25 ft., 20 ft.; and if 35 ft. or more, at least 25 ft.

Open String (*Carp. and Join.*) *See* CUT STRING.

—— (*Music*). In stringed instruments, whether bowed (*e.g.* the violin) or plucked (*e.g.* the guitar), a string is said to be OPEN when it is free to vibrate along its whole length, *i.e.* when it is not "stopped" by pressing the finger down upon it. *See* MUSICAL INSTRUMENTS.

Opera Glass (*Light*). An opera glass or field glass consists of a pair of telescopes, usually of the type invented by Galileo. There is a convex object glass of focal length F, and a concave lens of focal length f, separated by a distance $F - f$. The image is erect, and the magnification is in the ratio $\frac{F}{f}$.

Ophicleide (*Music*). A brass instrument which took the place of the serpent. The ophicleide has now given way to the tuba (*q.v.*) *See* MUSICAL INSTRUMENTS—WIND (BRASS).

Ophitic Structure (*Geol.*) A structure first noticed in the Ophites of the Pyrenees, which were so called on account of their resemblance in colour pattern to that of many snakes. Subsequently the same structure was found in other types of rocks. It consists essentially of a large patch constituting part of a single crystal of one mineral (and proved to be so by the examination of a thin section in polarised light), which encloses several crystals of another mineral in consequence of the period of consolidation of the two being different. Holocrystalline and Ophitic structures are characteristic of true dolerite, in which large plates of one of the Pyroxenes enclose

several crystals (usually lath shaped in form) of a Plagioclase felspar, which is generally Labradorite. Ophitic structure may occur in other rocks besides dolerite.

Opistodomus (*Architect.*) *See* CELL.

Opium (*Botany*). The drug is obtained from *Papaver somniferum* (order, *Papaveraceæ*) by incision of the unripe capsules, from which the latex exudes, and by evaporation becomes hard. Opium contains many alkaloids.

—— (*Chem.*) The dried juice from the unripe capsules of the white poppy (*Papaver somniferum*). It is a reddish brown soft mass, which hardens and deepens in colour when kept. Characteristic smell. It contains a large number of substances—resin, caoutchouc, albumin, and many (eighteen) alkaloids, the latter combined with meconic, acetic, and sulphuric acids for the most part. There are many varieties of opium, *e.g.* Smyrna, Egyptian, Indian, etc. These differ in the amount of alkaloids they contain, and are generally estimated for the morphine (*q.v.*) which they contain. The most important alkaloids contained in opium are Morphine, Narcotine, Codeine, Papaverine (*q.v.*)

Opoponax (*Botany*). A gum resin obtained from the milky juice of the roots of *Opoponax chironium* (order, *Umbelliferæ*). It is now used only in perfumery.

Opossum (*Zool.*) A marsupial mammal found in North and South America. *Didelphis virginiana* is the North American species, and is valued on account of its fur.

Opposition (*Astron.*) The position of a celestial body when its elongation is 180°. The moon at full is said to be in "opposition."

Optical Activity (*Phys.*, *Chem.*) The property possessed by certain substances of rotating the plane of polarisation of plane polarised light which traverses the substance.

Optical Centre of a Lens (*Photo.*) A point such that all rays whose direction *inside* the lens (or that direction produced, if the point lies outside the lens) passes through it emerge parallel to their original direction; the ray appears therefore to be undeviated if it pass through the optical centre of a thin lens. If normals be drawn to the two surfaces of the lens, so as to be parallel to each other, then a line drawn through the points where these normals cut the surfaces will in general intersect the axis at the centre of the lens.

Optical Isomerides (*Chem.*) Compounds which differ only in their behaviour towards a ray of plane polarised light. Examples of such substances are the different forms of lactic acid (*q.v.*), of tartaric acid (*q.v.*), of mandelic acid (*q.v.*), etc.

Optical Lantern. *Also termed* MAGIC LANTERN or simply LANTERN. It consists essentially of a BODY or box containing the source of light, a CONDENSER (*q.v.*), a support to carry the SLIDES, and an OBJECTIVE or, as it is also termed, a FOCUSSING or PROJECTION LENS. *See* LANTERN OBJECTIVE. The light may be obtained from an oil lamp (usually having several wicks), but more commonly the oxyhydrogen light (*q.v.*) or some form of electric light is used. An arc light produced by a continuous current is the best illuminant; the Nernst light is far the most convenient, and is for many purposes equal to the arc.

Optically Active Substances. Substances having the power to rotate the plane of polarisation of a ray of plane polarised light. *See* STEREOISOMERISM, ASYMMETRIC CARBON ATOM, *and* POLARISATION.

Optic Axis (*Light*). 1. The axis of symmetry of an optical system, more often termed the OPTICAL AXIS to distinguish it from the following. 2. A direction in a doubly refracting crystal along which the substance behaves as a singly refracting medium; *i.e.* a ray traversing the crystal in this direction is not split up into two. *See also* DOUBLE REFRACTION.

Opuntia (*Botany*). A genus of *Cactaceæ* native to America. The "prickly pear" (*O. vulgaris*) and "Indian fig" (*O. Ficus Indica*) are well known examples.

Or (*Her.*) The heraldic term for the metal gold. When arms are represented without colour in drawings or engravings, *or* is indicated by small dots. *See* HERALDRY.

Orange (*Botany*). The well known fruit of the evergreen tree *Citrus aurantium*, largely cultivated in subtropical regions. *See* CITRUS.

—— (*Paint.*) A colour produced by a mixture of red and yellow pigments. *See* COLOURS.

Oratory (*Architect.*, *etc.*) A small chapel, or a room in a house, monastery, or church, arranged for private worship.

Orb (*Her.*) *See* MOUND.

Orbit (*Astron.*) The path in which a heavenly body moves, *e.g.* that of the moon round the earth or the earth round the sun. CLOSED ORBITS are circles or ellipses. OPEN ORBITS are parabolas or hyperbolas.

Orchestra (*Architect.*) (1) In the theatres of the ancient Greeks a semicircular space in front of the stage. This space was occupied by the CHORUS (*q.v.*). The corresponding space in Roman theatres was occupied by seats intended for senators and other important persons. (2) In a modern theatre, etc., that part of the building occupied by the band of musicians.

—— (*Music*). (1) A body of instrumental performers. (2) The part of a building in which the instrumentalists and singers are placed.

Orchestration (*Music*). The art of writing for an orchestra; of employing the different kinds of instruments—stringed, wind, and percussion—to obtain contrast and tone colouring. Orchestration and instrumentation are the same.

Orchidaceæ (*Botany*). A well known order of *Monocotyledons* found in temperate and tropical climates. The essence known as Vanilla, obtained from *Vanilla planifolia*, is the only product of commercial value.

Orchil. *See* DYES AND DYEING.

Order (*Biol.*) A group of genera (*see* GENUS) which have certain characteristics in common, *i.e.* which resemble each other more than they do any other genera. Thus the genera *Rosa* (rose), *Pyrus* (apple, pear, etc.), *Fragaria* (strawberry), *Prunus* (plum), *Rubus* (blackberry, raspberry), etc., are grouped together to form the Order *Rosaceæ*.

Orders (*Architect.*) *See* ARCHITECTURE, ORDERS OF.

Ordinario (*Music*). Ordinary: usual.

Ordinary Ray (*Light*). *See* DOUBLE REFRACTION.

Ordnance Datum (*Surveying*). The ordnance or datum line by which all heights are fixed in the Ordnance Survey. It is 12½ ft. below Trinity high water mark, and 4½ ft. above Trinity low water mark.

Ordnance Survey (*Surveying*). The official survey of Great Britain and Ireland undertaken by the Government and carried out by officers selected from the Royal Engineers, who prepare maps and plans.

Ordovician (*Geol.*) A term proposed by Professor Lapworth for the great group of marine sediments and associated volcanic rocks which formerly went by the various names Upper Cambrian, Cambro Silurian, and "Lower Silurian." It is typically developed in Wales and in Cumberland. The use of the term prevents the ambiguity which that of any of the others carried with it.

Ore (*Mining*). A mineral or rock from which a substance of economic value can be extracted with profit. Thus Iron Pyrites (*q.v.*), though containing a considerable quantity of iron, is not an iron ore, since the iron cannot be profitably extracted; but it is an ore of sulphur, and is used extensively as such in the manufacture of sulphuric acid.

Oreillette (*Arm.*) The part of the helmet that protected the ears.

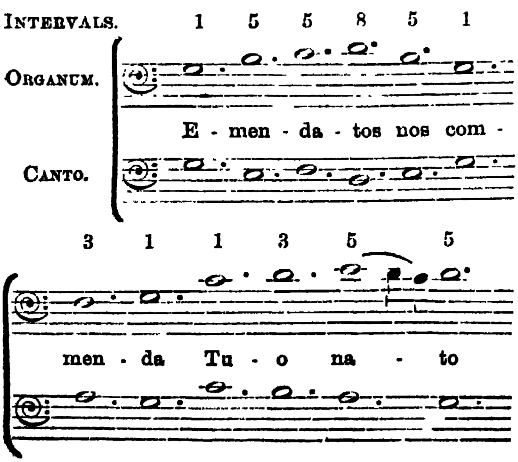
Organ (*Biol.*) A portion of an animal or plant having some definite function.

—— (*Music*). *See* MUSICAL INSTRUMENTS—WIND (KEYED).

Organic Chemistry. The chemistry of the carbon compounds. A few carbon compounds such as carbon monoxide, carbon dioxide, carbon disulphide, the carbonates, and the metallic carbides are usually dealt with in works on Inorganic Chemistry.

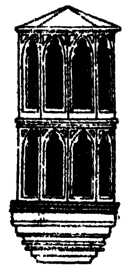
Organ Pipe Coral. *See* CORAL.

Organum (*Music*). An added part to the Canto Fermo (*q.v.*) in old music, which firstly was in unisons and octaves, then in consecutive fourths or fifths, fresh intervals gradually being allowed to be added through succeeding centuries. The following fragment of a hymn taken from Sir Hubert Parry's *Art of Music* will show the style of organum in the thirteenth century:



Organzine (*Silk Manufac.*) Silk thread for warp purposes, doubled and thrown of sufficient strength to stand the strain of weaving.

Oriel Window (*Architect.*) A bay window on an upper floor overhanging the face of the wall below.



ORIEL WINDOW.

Oriental Alabaster (*Min.*) *See* CALCITE.

Oriflamme (*Archæol.*) The banner of the Abbey of St. Denis: a banderole of orange red coloured silk, attached to a gilt lance and terminating in two points. It was the standard of the early kings of France, and was handed to them on setting out for war by the Abbot of St. Denis.

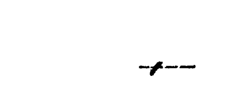
Origanum (*Botany*). A genus of *Labiatæ*. *O. vulgare* is the common herb Marjoram. Oil of Marjoram is distilled from *O. majorana*.

Orles (*Her.*) This is one of the subordinaries, a diminutive of the "bordure," but detached from the outer edge of the shield. Sometimes blazoned by early heralds as an inescutcheon voided. *See* HERALDRY.

Ornaments (*Music*). Embellishments, grace notes. The principal are: (1) THE TURN, which is indicated by a ~ placed above or below a note. When an accidental is placed above or below any ornament it shows that the highest or lowest note respectively is to bear that accidental.

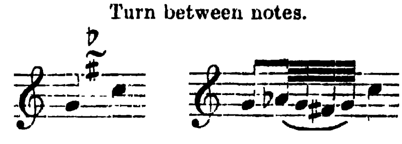
Written. Played.

Turn over a note.



Turn over a dot.

Turn between notes.

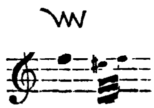


(2) THE INVERTED TURN is indicated by ≀ or

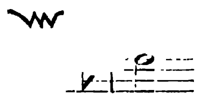
Written. Played.

(3) THE SHAKE, or TRILL, which is indicated by *tr.* or *tr*, and consists of a rapid alternation of the

principal (written) note with the diatonic note above, which may be either a semitone or tone according to the degree of the scale on which the shake appears. Care must be taken to see in what key the shake appears, as the diatonic note above of the temporary key is the one to be used. Bach, Handel, Mozart, Haydn, and other composers of the eighteenth century generally commenced the shake with the note above, except in the case of a shake commenced immediately after a rest, which was termed *trill ex abrupto*, when the shake always commenced on the principal note. Hummel and later composers, excepting Chopin, who reverted to the older style of Bach, commenced with the principal note. Bach generally indicated the shake as follows:



or by a note of anticipation after the W, as—

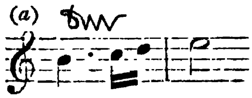


A shake usually, though not invariably, ends with a turn.

THE SHAKE.

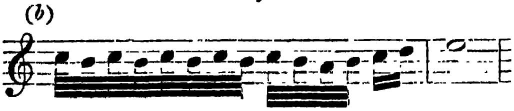
Written.

(a)

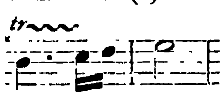


Played.

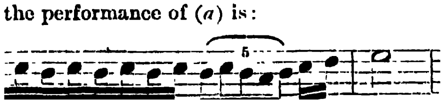
(b)



In modern music this shake (*b*) is written:



whilst the performance of (*a*) is:



(4) **The Mordente**, and (5) **The Inverted Mordente**, also called **Pralltriller** or **Schneller**. These (4 and 5) are shown under **Mordente**, p. 413. (6) **The Slide, Schleifer**, or **Tierce Coulée**.

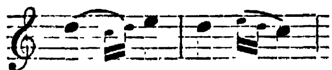
THE SLIDE.

Written. Played.

Written. Played.

It will be seen that the accent always falls on the principal note, and that the time taken by the ornamental notes is robbed from that principal note, whereas in the *Nachschlag* the time of the small notes is taken from the preceding note. The following shows the *Nachschlag* and *Schleifer*:

Written.

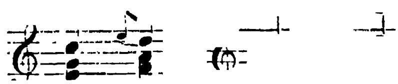


Nachschlag. Schleifer.

Played.

The slur shows which is the schleifer. (7) The Appoggiatura (*q.v.*):

Written. Played.

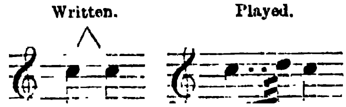


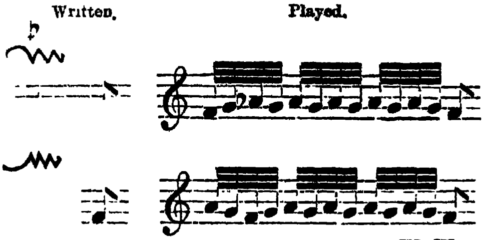
(8) The Acciaccatura (*q.v.*):

Written. Played.

In addition to the above, there were in older music other ornaments, a few of which are shown below:

Written. Played.





W. W.

Orpiment (*Min.*) Sulphide of arsenic, As_2S_3. Arsenic = 61, sulphur = 39 per cent. Orthorhombic, but usually in foliated masses, not in crystals. Of a beautiful lemon yellow colour. Sectile and flexible. The artificial orpiment is used as the pigment King's Yellow. From Bohemia, Hungary, Transylvania, etc.

—— (*Paint.*) A rich yellow pigment compounded from sulphur and arsenious oxide.

Orris Root (*Botany*). The prepared rhizomes of *Iris florentina* (order, *Iridaceæ*) are extensively used in perfumery and in the manufacture of "Essence of Violets."

Orr's Zinc White (*Dec.*) *See* ZINC WHITE.

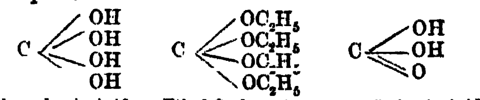
Orthochromatic (*Photo.*) This term is generally understood to mean the correct rendering of the luminosity or brightness of colours in monochrome by photographic means.

Orthochromatic Plate (*Photo.*) A plate which has been specially prepared for photographing coloured objects, and in which the colour sensitiveness has been obtained by the addition of certain dyes to the emulsion. In order, however, to gain full advantage of this addition, it is necessary to employ an orange screen to cut off some of the blue and violet light. The proper selection of this screen is a matter of importance, as should it absorb too much of these rays, those colours would photograph too dark.

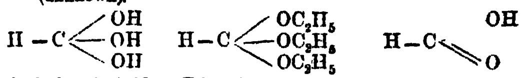
Orthochrom T. (*Photo.*) A sensitising dye stated to give to photographic plates sensitiveness for green, yellow, orange, and red, and to confer a high degree of sensitiveness generally.

Orthoclase (*Min.*) Aluminium and potassium polysilicate, $K_2O . Al_2O_3 . 6SiO_2$. Silica = 64·2, alumina = 18·4, potash = 16·95 per cent. Monosymmetric, in thick prisms; often twinned in one of three ways, the twin planes being respectively parallel to the orthopinacoid, to a clinodome, and to the basal plane, in the Carlsbad, Baveno, and Manebach types of twinning. Colour: white, grey, red, and in the variety Amazonstone, green. Sunstone and moonstone are other varieties which are used by lapidaries. In Cornwall, Aberdeen, Bohemia, Norway, Switzerland, etc.

Ortho-Compounds (*Chem.*) The prefix ortho is used in chemistry in two ways. First, to denote what may be called a normal or ordinary compound, as distinguished from others which are not normal. Examples: Orthophosphoric acid was so called when other phosphoric acids were discovered, and had to be distinguished from it. Orthoboric acid is so called because it is the normal or common boric acid, and has to be distinguished from other boric acids. The prefix is also used in organic chemistry to distinguish derivatives of certain unknown acids which are related to the ordinary carboxylic acids in such wise that the latter are anhydrides of the former. Examples:

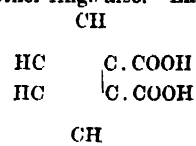


Orthocarbonic Acid (unknown). Ethyl Orthocarbonate. Carbonic Acid.

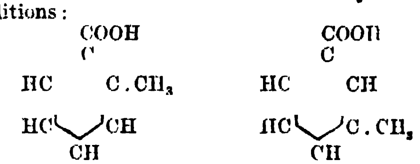


Orthoformic Acid (unknown). Ethyl Orthoformate. Formic Acid.

Second, the prefix is used to denote two adjacent positions in the benzene ring (*see* BENZENE), and occasionally in other rings also. Example:



which is phthalic acid, may be called benzene orthodicarboxylic acid. A ring consisting of four carbon and two nitrogen atoms is known as the diazine ring, and when the nitrogen atoms are adjacent we have the orthodiazine ring. Ortho-compounds have certain characteristic features; *e.g.* ortho-acids form anhydrides. *See* PHTHALIC ACID. Orthodiamines give many condensation reactions which meta- and paradiamines do not give. An ortho-substituent often hinders a reaction in which its fellow ortho-substituent is concerned. Thus, in making the ethyl esters of the toluic acids, while 59 per cent. of meta-acid was made into ester, only 26 per cent. of the ortho-acid was formed under exactly the same conditions:



Orthotoluic Acid. Metatoluic Acid.

Orthodiagonal (*Min.*) The lateral axis of the monosymmetric system which is at right angles to the principal axis.

Orthodome (*Min.*) A form of the monosymmetric system: it is a prism whose axis is the orthodiagonal; the four faces are regarded in opposite pairs of two.

Orthopinacoid (*Min.*) A form of the monosymmetric system whose faces are parallel to both the orthodiagonal and to the vertical axis.

Ortol (*Photo.*) This developer is said to be a mixture of hydroquinone with a sulphate of methyl-ortho-amido-phenol, $C_6H_4OHNHCH_3$. It is readily soluble in water, and produces a colourless solution. Ortol by itself has no developing power, but on the addition of sodium carbonate development takes place rapidly.

Oryza (*Botany*). A genus of grasses, including the rice plant (*O. sativa*).

Os (*Chem.*) The symbol for OSMIUM (*q.v.*)

Osazones (*Chem.*) Dihydrazones in which hydrazine residues are attached to adjacent carbon atoms. Only osazones derived from phenyl hydrazine,

$C_6H_5NHNH_2$, are mentioned in this article; such osazones are usually termed phenylosazones, but they will be called simply osazones for brevity. The simplest osazone is derived from glyoxal or from the simplest possible sugar glycolose, which is the monohydric alcohol of glyoxal:

$$\begin{array}{l} HC:O \\ \quad | \\ HC:O \\ \text{Glyoxal.} \end{array} + \begin{array}{l} H_2N.NHC_6H_5 \\ \\ H_2N.NHC_6H_5 \\ \\ \end{array} = \begin{array}{l} H.C:N.NHC_6H_5 \\ \qquad | \\ H.C:N.NHC_6H_5 \\ \\ \end{array} + 2H_2O$$

$$\begin{array}{l} H.C{<}\begin{smallmatrix} H \\ OH \end{smallmatrix} \\ \quad | \\ H.C:O \\ \text{Glycolose.} \end{array} + 3H_2N.NHC_6H_5 = \begin{array}{l} H.C:N.NHC_6H_5 \\ \qquad | \\ H.C:N.NHC_6H_5 \\ \text{Glycolose Osazone.} \end{array} +$$

$$2H_2O + NH_3 + C_6H_5NH_2$$

Osazones are formed by substances of the general formulæ:

$$\begin{array}{ccc} R & R & R \\ | & | & | \\ (1)\ CO & (2)\ CO & (3)\ CHOH \\ | & | & | \\ CO & CH_2OH & CHO \\ | & & \\ R & & \end{array}$$

where R may be hydrogen or a complex group. All sugars containing aldehyde and ketone groups form osazones, and their osazones serve to distinguish between them, *e.g.* dextrose and lactose, which resemble each other closely in their tests, can easily be distinguished by making their osazones and examining the latter under the microscope. They are all prepared in a similar manner; *e.g.* to make glucosazone, 1 part glucose in 20 parts water is warmed for an hour and a half (for the best yield) on the water bath, with 2 parts phenylhydrazine hydrochloride and 3 parts sodium acetate, when the osazone crystallises out. It may be recrystallised from alcohol. Osazones are yellow crystalline solids, insoluble in water, soluble in alcohol. The osazones of the sugars have only a definite melting point when rapidly heated. They possess reducing properties. The action of hydrochloric acid on glucosazone is very important: it yields phenylhydrazine hydrochloride and glucosone:

$$\begin{array}{l} CH_2OH \\ \quad | \\ (CHOH)_3 \\ \quad | \\ C:N.NHC_6H_5 \\ \quad | \\ H.C:N.NHC_6H_5 \\ \\ \end{array} + 2H_2O = \begin{array}{l} CH_2OH \\ \quad | \\ (CHOH)_3 \\ \quad | \\ CO \\ \quad | \\ HCO \\ \text{Glucosone.} \end{array} + 2H_2N.NHC_6H_5.$$

The glucosone on reduction with zinc dust and dilute acetic acid yields lævulose. Thus glucose (*q.v.*) can be converted into lævulose. Other osazones of the sugars also yield osones in a similar way.

Oscillating Cylinder (*Eng.*) A cylinder swinging on pivots, termed TRUNNIONS, and having its piston rod connected directly to the crank pin, without any connecting rod.

Oscillation. A general term for a "to and fro" movement, however produced.

——, **Centre of.** *See* PENDULUMS.

Oscillations, Electrical (*Elect.*) *See* OSCILLATORY DISCHARGE.

Oscillatory Discharge (*Elect.*) If the plates of a charged condenser be connected by a conductor (whose resistance does not exceed a certain value) a series of very rapid alternations of charge are set up, the plates of the condenser becoming in turn positively and negatively charged. An alternating current of very high frequency thus flows in the conductor; but it rapidly dies away as the original energy of the charged condenser is dissipated in the form of heat. If C be the capacity of the condenser, L the self induction, and R the resistance of the circuit by which the plates are connected, there will be no oscillations if R^2 be greater than $\frac{4L}{C}$. If the resistance be small, the period of the oscillations is approximately $T = 2\pi\sqrt{LC}$.

Oscillograph (*Elect.*) An instrument for showing the changes in a rapidly varying current or E.M.F., *e.g.* for indicating the wave form of an alternating current. It is in principle a galvanometer whose natural period of vibration is very small compared with the period of the alternating current.

Osirid Pier (*Architect.*) A form of pier used in Egyptian architecture, *e.g.* at Luxor, having a colossal figure of Osiris carved on its front face.

Osler's Anemometer (*Meteorol.*) An instrument invented by Osler for determining the pressure of wind. By means of clockwork a record of this pressure is obtained for every instant of time.

Osmiridium (*Chem.*) *See* IRIDIUM.

Osmium and its Compounds (*Chem.*) Os. Atomic weight, 191. A bluish white metal; infusible in anything except the electric arc; sp. gr. 22·5, that is to say, the heaviest metal known; oxidises to the volatile tetroxide when heated in air; insoluble in aqua regia after it has been strongly heated, not otherwise; heated in chlorine, it forms, according to the amount of chlorine, $OsCl_2$, $OsCl_3$, $OsCl_4$. Osmium can be crystallised from its solution in tin. The metal occurs along with platinum, and remains behind as OSMIRIDIUM (*see* IRIDIUM) when the ore is treated with aqua regia. It is obtained by converting the osmium in the alloy into the tetroxide, which is volatile (*see* IRIDIUM); the tetroxide is dissolved in caustic potash, and the solution reduced with alcohol to potassium osmate, K_2OsO_4, which is dissolved in water and precipitated with ammonium chloride. The precipitate heated in hydrogen yields the metal. Several oxides are known ($OsO_2 : Os_2O_3 : OsO_3 : OsO_4$). Only the tetroxide OsO_4 is important; it is often called osmic acid. It is formed by heating the metal in air, when the oxide sublimes in shining needles. It is soluble in water, alcohol, ether. Smells like chlorine, readily volatile, distils in steam. The vapour attacks the eyes and mucous membrane in a dangerous way. Its aqueous solution is reduced by many metals. Sulphur dioxide forms a blue solution. It has feeble acid properties, but does not redden litmus. Used as a stain in microscopy. Forms compounds of unknown nature with the albumins. Osmium forms complex cyanogen and ammonium compounds.

Osmosis (*Phys.*, *Chem.*) If two liquids be separated by a porous partition, there will be in general a tendency for the liquids to traverse the partition—*e.g.* let a solution of copper sulphate in water be separated from pure water by a partition consisting of a sheet of parchment; the water will pass through in one direction, and the dissolved substance in the other. This process is termed OSMOSIS.

Osmotic Pressure (*Phys.*, *Chem.*) Let a solution and a solvent be separated by a semi-permeable partition, which permits the passage of the solvent,

but not of the dissolved substance. The solvent will pass through until it exerts equal pressure on both sides of the partition; the total pressure exerted by the solution will then exceed that exerted by the solvent by an amount equal to that exerted by the dissolved substance alone. This amount is termed the OSMOTIC PRESSURE of the dissolved substance. In the case of a dilute solution (if it is not an electrolyte) the osmotic pressure obeys laws very closely resembling the fundamental laws of gases: (1) it is proportional to the concentration; (2) its variation with temperature is the same for all substances, the pressure probably being proportional to the absolute temperature; (3) solutions containing the same number of dissolved molecules per unit volume exert the same pressure. *See also* SOLUTIONS.

Osones (*Chem.*) *See* OSAZONES.

Ossia (*Music*). Or this instead. An alternative passage of music.

Ossicles, Auditory (*Zool.*) A series of small bones (the *malleus*, *incus*, and *stapes*) in the tympanic chamber of the ear. They serve to convey the vibrations from the tympanic membrane ("drum") to the internal ear.

Ostensoir, Ostensory. A monstrance (*q.v.*) for displaying the Host to the congregation.

Ostinato (*Music*). A ground bass, *i.e.* a bass which repeats over and over again in a composition. A fine example may be found in J. S. Bach's Passacaglia in C minor for the organ.

Ostrich (*Zool.*) A family (*Struthionidæ*) of the subclass *Ratitæ*, or flightless birds. The common African ostrich (*Struthio camelus*) differs slightly in colour from the Somali type (*S. molybdophanes*). The plumage forms a valuable article of trade.

Ottava (*Music*). An octave; *e.g.* ottava bassa or 8va bassa, an octave lower.

Ottoman *or* **Royal Cord** (*Silk Manufac.*) A plain corded silk, woven as Gros, with three or more picks in the same shed, but having an additional binder warp, the threads of which intersect each pick, keeping them apart and giving the cord an extended flat appearance.

Ottoman Rib (*Textile Manufac.*) Also termed SOLEIL. A ribbed fabric in which lines or bars traverse the cloth, but on which the rep is formed entirely in the warp.

Ounce. *See* WEIGHTS AND MEASURES.

Out (*Typog.*) When a compositor has omitted any words, a line or sentence, each omission is called an "out."

Outcrop (*Geol.*) The outer edge of strata where these come either directly to the surface or end off against some newer formation. The form of the outcrop varies on the one hand with the dip or inclination of the strata, and on the other with the shape of the surface which intersects those strata.

Outer Forme (*Typog.*) The forme that contains the first page of a sheet.

Outer String (*Carp. and Join.*) In a staircase the string (*q.v.*) farthest from the wall, *i.e.* the string over which the handrail is fixed.

Outer Tympan (*Typog.*) A frame used on hand presses. It is covered with parchment, and each sheet of paper to be printed is placed upon it. *See* TYMPANS.

Outfall Sewers (*Civil Eng.*) The large main channel conveying sewage (after it leaves the area of collection) to the place where it is to be disposed of.

Outgo (*Plumb., etc.*) The outlet of a trap.

Outlier (*Geol.*) A portion of a stratum which has been isolated from the main mass by the removal of some of the rock around, so that the outlying mass is surrounded on all sides by strata of older date. *Cf.* INLIER.

Outline (*Art, etc.*) (1) The contour of a figure, or the line or lines by which it is bounded in the plane of vision. (2) A drawing which represents an object merely by lines, not a finished view.

Out of Gear (*Eng., etc.*) (1) Gear or spur wheels are out of gear when their teeth do not engage with each other. (2) A general expression for "out of order."

Out of Register (*Print.*) (1) When pages on one side of a sheet do not fall exactly within the area of those printed on the other side, or when line does not fall upon line, or (2) when a work or design is produced in more than one colour and the separate printings do not fall into their proper positions, the work is said to be "out of register."

Output. (1) The energy developed in a given time by any prime mover or source of energy. (2) The amount of work produced by a workman, machine, factory, etc.

Outside Callipers (*Eng., etc.*) Callipers (*q.v.*) with the points curved inward, so as to enable the external diameter of an object to be measured by them.

Outside Crank (*Eng.*) A crank consisting of, or equivalent to, a single lever arm placed at the end of the crank shaft.

Outside Cylinders (*Eng.*) Cylinders of a locomotive placed outside the main frame.

Outside Gouge (*Carp., etc.*) A gouge with the bevel on the outer or convex surface; the ordinary form of carpenter's gouge.

Outside Lap (*Eng.*) *See* SLIDE VALVE.

Outside Lining (*Carp. and Join.*) The linings of a cased frame nearest the reveals.

Outside Reams (*Print.*) Reams of machine or hand made paper containing two quires of imperfect sheets, one quire placed at the top and one at the bottom. The price of "outside" reams is usually 20 per cent. lower than that of "good."

Out to Out (*Build., etc.*) In measurements this term means that the dimensions are taken over all.

Ouvarovite (*Min.*) A calcium chromium garnet of approximate composition, $SiO_2=35$, $Al_2O_3=5$, $Cr_2O_3=22$, $CaO=30$ per cent. Cubic. in dodecahedral crystals of emerald green colour. From the Ural Mountains.

Oval. A closed curve of an egg shape, not to be confused with the ellipse. An oval is symmetrical only about its longer axis.

Oven Coke (*Met.*) Coke specially prepared by heating in closed chambers, and retaining a much larger amount of carbon than ordinary gas coke.

Over All *or* **Sur (le) Tout** (*Her.*) A bearing that surmounts or is placed over others in the field is said to be over all.

Overblowing (*Music*). A term used when too much wind is forced through a pipe, causing it to sound one of the harmonics instead of its fundamental tone.

Overcasting (*Bind.*) *See* OVERSEWING.

Overcoil (*Watches*). The outer coil of a Breguet balance spring. *See* BREGUET SPRING.

Over-Compounded Dynamo (*Elect. Eng.*) A dynamo whose windings are so arranged that the voltage at the terminals increases as the load is increased.

Overcrowding (*Hygiene*). Under the Factories and Workshops Act overcrowding in workrooms is deemed to exist when the cubic space for each adult is less than 250 cubic ft., and during overtime less than 400 cubic ft. The minimum standard laid down by the Local Government Board Model Byelaws is 400 cubic ft. per adult (two children under ten to count as one adult) for rooms in which persons both live and sleep, and 300 cubic ft. for rooms used solely for living. *See also* FLOOR SPACE.

Over-Exposure (*Photo.*) An over exposed image appears very quickly during development; but the contrasts between light and shade are not sufficiently marked. This fault may be lessened by using a developer with a small amount of alkali, or by submitting the finished negative to INTENSIFICATION (*q.v.*)

Overflow (*Plumb.*) An outlet pipe fixed to a cistern near the top to prevent the water overflowing.

Overhand Stoping. *See* MINING.

Overhanging Shaft (*Eng.*) A shaft whose end projects some distance beyond the bearing; a pulley on this end is termed an OVERHANGING PULLEY.

Overhauling (*Eng.*) (1) The reversal of the motion of a crane, crab, or other lifting gear, whereby the load descends by its own weight. (2) A general term for the examination of a machine, etc., with a view to repairs.

Overhead Crane *or* **Traveller** (*Eng.*) A crab or crane running on rails mounted on standards or girders so as to travel along a shop above the level of the machinery, in order to lift heavy pieces of work.

Overhead Gear (*Mining*). The HEAD GEAR or structure over a shaft which supports the hauling tackle.

Overhead Railways (*Civil Eng.*) Railways carried on arches, iron or steel viaducts, etc. Examples are the New York, Berlin, and Liverpool Elevated Railways. The first two run along streets, carried on an iron viaduct supported by iron columns; the latter extends for 6 miles behind the docks.

Overhead Trolley (*Elect. Eng.*) *See* ELECTRIC TRACTION.

Overhead Wires, etc. (*Elect. Eng.*) Any system of conducting wires, either bare or insulated, supported at intervals by poles or arms. The wire is of course insulated from the pole at the point of contact; the common system of telegraph wires is a good example of bare overhead wiring.

Overlap (*Eng., etc.*) The amount by which two plates cross each other at a riveted joint, etc.

—— (*Geol.*) A stratum is said to overlap another in cases where the lower one is locally absent. The use of the term is now usually confined to instances in which the two strata referred to belong to the same geological formation. Overlap implies deposition against a sloping surface.

Overlay (*Print.*) Used in connection with the printing of illustrations. Proofs are pulled on three or more pieces of paper of varying substance, and parts are "peeled" or cut away from each. Then all are lightly pasted together and placed in position over the block to be printed, so that the greater thickness is brought to bear upon the darker portions of the picture, the medium upon the intermediate, and the thinnest upon the background or lighter details.

Overpick (*Weaving*). The system of picking in which the picking arm is over the going part or shuttle boxes. Both light and heavy built looms are mounted with this kind of picking motion.

Overpoled Copper (*Met.*) *See* COPPER.

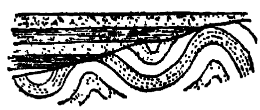
Overrun (*Typog.*) If in a printer's proof any matter is marked to be taken out or inserted, words or lines are transferred from one line or page to another to preserve uniform length. This is termed overrunning.

Oversailing (*Build.*) Overhanging. *See also* CORBELLING.

Oversewing *or* **Overcasting** (*Bind.*) The method of sewing adopted when single leaves, *e.g.* plates, are to be attached to the sections or folded sheets at the end of a book, or when a book consists entirely of single leaves. In the latter case a certain number of leaves, four, six, or eight, are connected together by oversewing, so as to form sections for further treatment, the thread being fastened at the head and tail of each section.

Overshot Wheel (*Eng., etc.*) A water wheel which is driven by water entering the buckets at the top of the wheel.

Overstep (*Geol.*) A stratum is said to overlap another older one in those cases in which the relation between the two is that of an unconformability (*q.v.*) The older strata have, in this case, undergone prior disturbance and denudation, and the newer have been deposited after the movements which caused the disturbance had ceased. Overlap and overstep may coexist in the same section, as is the case in the figure.



OVERSTEP.

Overtone (*Sound, Music*). A sound of higher pitch produced by a vibrating body along with its fundamental tone. Overtones accompany almost every tone which it is possible to produce, and can be detected in very many cases. *See also* HARMONICS.

Overtones (*Music*). Harmonics (*q.v.*)

Ovolo (*Architect.*) A convex moulding. The Roman ovolo is a quarter circle, but the ovolo used by the Greeks is a flatter and more graceful curve. The ovolo is also used, but not extensively, in Decorated Gothic work. *See* CYMA, ECHINUS, *and* COLUMN.

Ovule (*Botany*). The egg shaped body developed within the ovary of a flower, and which after fertilisation becomes the seed.

Ovum (*Zool.*) An Egg Cell, the structure from which an animal is developed after fertilisation or union with a male cell or spermatozoon.

Ox (*Zool.*) *Bos taurus* (family, *Bovidæ*). Apart from the use of the flesh as food, the horns are made into various articles (combs, knife handles, etc.); the cartilages and skin cuttings yield glue; the hide, leather; and that of the calf, vellum.

Oxalates (*Chem.*) *See* OXALIC ACID.

Oxalic Acid (*Chem.*) $\begin{array}{l}COOH\\ |\\ COOH.\end{array}$ White crystalline (monoclinic prisms) solid; crystallises with $2H_2O$; loses its water of crystallisation at 100°; poisonous. On heating, it sublimes in part, and part decomposes to carbon dioxide and formic acid, the latter also partly decomposing to carbon monoxide and water. Heated with glycerine, it gives formic acid (*q.v.*) at 110°, and at a high temperature allyl alcohol. Readily soluble in water and in alcohol; less soluble in ether. Its dilute aqueous solution decomposes on keeping in presence of light. Heated with strong sulphuric acid it gives carbon monoxide and carbon dioxide, the sulphuric acid removing a molecular proportion of water; phosphorus pentachloride reacts in a similar way:

$$\begin{array}{l}COOH\\ |\\ COOH\end{array} + PCl_5 = POCl_3 + 2HCl + CO + CO_2.$$

Oxidising agents, such as acidified potassium permanganate, readily oxidise it to carbon dioxide and water.

$$\begin{array}{l}COOH\\ |\\ COOH\end{array} + O = 2CO_2 + H_2O.$$

Sodium amalgam yields glyoxylic acid with a strong aqueous solution of oxalic acid:

$$\begin{array}{l}COOH\\ |\\ COOH\end{array} + 2H = \begin{array}{l}CHO\\ |\\ COOH\end{array} + H_2O.$$

It is a dibasic acid. Oxalic acid occurs chiefly in the form of its calcium and acid potassium salts; the former is very widely distributed in plants, and is present in urine, and forms also a urinary calculus; the latter also occurs in many plants, *e.g.* sorrel (hence it is called salt of sorrel) and rhubarb. The acid may be obtained synthetically by passing carbon dioxide over finely divided sodium (shaking melted sodium with sand) at 300°:

$$2CO_2 + 2Na = \begin{array}{l}COONa\\ |\\ COONa.\end{array}$$

To obtain the acid from the sodium oxalate, precipitate its solution with calcium chloride and decompose the calcium oxalate with dilute sulphuric acid; decant and crystallise. When an aqueous solution of cyanogen is allowed to stand, ammonium oxalate is formed besides other products, showing that cyanogen may be regarded as the nitrile of oxalic acid:

$$\begin{array}{l}CN\\ |\\ CN\end{array} + 4H_2O = \begin{array}{l}COONH_4\\ |\\ COONH_4.\end{array}$$

The pure acid is best obtained by heating cane sugar with six times its weight of concentrated nitric acid till reaction sets in, allowing it to proceed alone, concentrating, and leaving to crystallise. On the large scale it is obtained by heating the sawdust of a light wood with caustic potash and water, extracting with water, precipitating the solution with milk of lime, and decomposing the calcium oxalate with dilute sulphuric acid. The clear liquid is then crystallised. The following oxalates are important: AMMONIUM OXALATE, $(NH_4)_2C_2O_4$, obtained by neutralising oxalic acid with ammonia; used as a test for calcium. On heating it, some oxamide is formed:

$$\begin{array}{l}COONH_4\\ |\\ COONH_4\end{array} = \begin{array}{l}CONH_2\\ |\\ CONH_2\end{array} + 2H_2O.$$

Heated with phosphorus pentoxide it yields cyanogen. CALCIUM OXALATE, CaC_2O_4, has been mentioned above; it is nearly insoluble in water and in acetic acid; soluble in hydrochloric acid; on heating it gives calcium carbonate and carbon dioxide. FERROUS OXALATE, FeC_2O_4, obtained as a yellow powder on adding a solution of oxalic acid to one of ferrous sulphate; on heating it leaves behind finely divided ferric oxide; its double salt with potassium oxalate, $K_2Fe(C_2O_4)_2H_2O$, is a powerful reducing agent, and is used in photography. *For* ETHYL OXALATE, *see* ETHYL OXALATE, ETHYLAMINES, KETIPIC ETHYL ESTER.

Oxidation (*Chem.*) Oxidation is a name given to any one of three operations, *viz.*

(1) Addition of oxygen to a substance.
(2) Removal of hydrogen from a substance.
(3) The change of an *-ous* salt into an *-ic* salt.

(1) Examples of this process are the combustion of hydrogen in oxygen, the conversion of benzaldehyde on exposure to air or oxygen into benzoic acid, the oxidation of oxalic acid to carbon dioxide and water by an acidified solution of potassium permanganate. Those oxidations which are brought about by free oxygen, and which run spontaneously, are sometimes called autoxidations. The process of addition of oxygen to a substance to form another containing more oxygen is usually not a simple one; there are intermediate reactions. Thus, when hydrogen burns in air or oxygen, a part, at all events, of the water produced arises from the formation and subsequent decomposition of hydrogen peroxide:

$$H_2 = H + H$$
$$H + H + O_2 = \begin{array}{l}H-O\\ \;\;|\\ H-O\end{array} = H_2O + O$$

This is shown by the fact that hydrogen peroxide is always produced in fair quantity when a jet of burning hydrogen is made to play on a piece of ice.

When benzaldehyde is exposed to air, a peroxide is first formed by addition of a molecule of oxygen, and this peroxide oxidises a second molecule of benzaldehyde to benzoic acid, and is itself reduced to the same.

$$C_6H_5C\begin{array}{l}\diagup H\\ \diagdown\!\!\diagdown O\end{array} + O_2 = C_6H_5C\begin{array}{l}\diagup O-O-H\\ \diagdown\!\!\diagdown O\end{array}$$

Benzoylhydroperoxide.

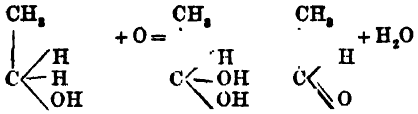
$$C_6H_5C\begin{array}{l}\diagup O-OH\\ \diagdown\!\!\diagdown O\end{array} + C_6H_5C\begin{array}{l}\diagup H\\ \diagdown\!\!\diagdown O\end{array} = 2C_6H_5C\begin{array}{l}\diagup OH\\ \diagdown\!\!\diagdown O\end{array}$$

When a substance is present which the benzoylhydroperoxide can oxidise more readily than it can benzaldehyde, then this substance is oxidised. For example, indigo; then the indigo is oxidised by one of the added oxygen atoms, and the other remains to form benzoic acid.

The two cases, hydrogen and benzaldehyde, are

typical of a very large number of quite similar reactions which are known.

(2) An example of this is the oxidation of alcohol to aldehyde. Here also previous addition of oxygen may be assumed to occur with formation of an unstable compound which breaks down into water and aldehyde:



(3) This kind of change corresponds to the conversion of the salt of a lower oxide into one of a higher oxide, hence it is called an oxidation. The process is, however, electrolytic in character; it consists in adding to the kation a positive charge equal to that carried by a hydrogen ion or a multiple thereof. For example, when oxygen is passed through a solution of ferrous sulphate acidified with sulphuric acid, the hydrogen ions give up their charges to iron ions, and form water with the oxygen:

$$2\overset{++}{Fe} + 2\overset{=}{SO_4} + 2\overset{+}{H} + \overset{=}{SO_4} + O = 2\overset{+++}{Fe} + 3\overset{=}{SO_4} + H_2O.$$

The process of oxidation is effected by reagents or mixtures of reagents, which are called oxidising agents. Examples of oxidising agents are: Oxygen, chlorine in presence of water, nitric acid, hypochlorous and hypobromous acids and their salts, potassium permanganate alone or in presence of sulphuric acid or caustic potash, chromic acid or potassium dichromate acidified with sulphuric acid, ferric chloride, nitrobenzene, and many others. All these reagents act by providing oxygen, except ferric chloride, which gives up chlorine, and the latter removes hydrogen from the compound it oxidises, *e.g.*

$$2FeCl_3 + H_2S = 2FeCl_2 + 2HCl + S.$$

Examples of the action of oxygen are given above. Chlorine oxidises in virtue of its action on water, liberating oxygen:

$$H_2SO_3 + Cl_2 + H_2O = H_2SO_4 + 2HCl.$$

See NITRIC ACID, MANGANESE COMPOUNDS, POTASSIUM COMPOUNDS, HYPOCHLOROUS ACID, LAUTH'S VIOLET, METHYLENE BLUE, ANTHRAQUINONE, QUINOLINE. Chromyl dichloride (*see* CHROMIUM COMPOUNDS) is a valuable oxidising agent in organic chemistry.

Oxide of Zinc (*Dec.*) A valuable white pigment. It is usually manufactured by extracting the metal from zinc ore and burning this metallic zinc in a special furnace. The zinc being heated to a temperature slightly above that of its melting point, it takes fire and burns, giving off dense fumes, which are conducted by means of bags of muslin or other material. These bags are from 30 to 90 ft. long, and in them the fumes at once form what are known as "flowers of zinc." These collect in the bags attached to the main chamber, which are regularly emptied at frequent intervals. Under ordinary conditions six charges may be taken out in one day. The oxide of zinc is then passed through sieves with a very fine mesh, and is ready for use. ZINC WHITE is extensively used in the manufacture of paints, about 85 per cent. of the total quantity produced being used for this purpose. The remainder is used in various industries, including the manufacture of floorcloths, wallpaper, rubber, and for glazing earthenware, etc. The use of late has increased very rapidly owing to the attention of the public having been drawn to the poisonous effects of using white lead. Oxide of zinc possesses the advantage of being much whiter and finer than lead. The whiteness is of importance not only when the work is to be finished in white, but also when the pigment is to form the base of a coloured paint, as freedom from any yellowish cast retains the purity of tint of the added colours. The durability is claimed to be greatly superior to white lead paints, owing principally to the fact that it is uninfluenced by sulphuretted hydrogen and other gases, which are found in the air of all large towns, as well as in the vicinity of stables, lavatories, etc., and which have a disastrous effect upon white lead, changing its chemical nature entirely, and causing it to discolour or turn black. Among painters zinc white is not yet so popular as it should be, probably owing to the fact that it requires to be mixed differently from white lead. When purchased ground in oil in the ordinary way, it should be mixed with refined boiled oil only, and only sufficient turpentine to render it of suitable consistency for application to the work by means of a brush.

Oxides (*Chem.*) Compounds of two elements, one of which is oxygen, are called oxides. The word oxide is also used in organic chemistry to denote compounds formed by the union of alcohol and acid radicals with oxygen. Thus ether is sometimes called diethyloxide, $C_2H_5 - O - C_2H_5$. For convenience the oxides may be divided into several classes, *viz.* BASIC OXIDES, PEROXIDES, and ACID OXIDES; but the division is not a sharp one, for an oxide may belong to more than one class, *e.g.* aluminium oxide is both a basic oxide and an acid oxide. Basic oxides are usually the lower oxides of metals, form salts and water with an acid, and unite directly with acid oxides to form salts, and some unite with water to form alkaline hydroxides (alkalis). Example: $BaO + 2HCl = BaCl_2 + H_2O$: $BaO + SO_3 = BaSO_4$: $BaO + H_2O = Ba(OH)_2$. Basic oxides are made by heating the metal in air or by heating its carbonate, hydroxide, or nitrate, whichever may be most convenient or economical. Peroxides contain more oxygen than basic oxides, and give oxygen on being heated. They give chlorine when heated with hydrochloric acid, oxygen when heated with sulphuric acid. Some peroxides give hydrogen peroxide with dilute acids in the cold, *e.g.* BaO_2 and Na_2O_2. Peroxides can be obtained by heating basic oxides carefully in oxygen, or by heating them with an oxidising agent such as potassium chlorate. Acid oxides are non-metallic oxides, or the highest oxides of metals. They unite with water to form acids and with basic oxides to form salts, *e.g.* $SO_3 + H_2O = H_2SO_4$ and $SO_3 + PbO = PbSO_4$. General methods of formation cannot be given. Sesquioxides are so called because the ratio of the oxygen atoms to the atoms of the other elements is $1\frac{1}{2} : 1$, and not because of any reaction common to them as a class. They have the general formula R_2O_3. Examples: B_2O_3 : Fe_2O_3 : Al_2O_3 : Cr_2O_3. *See also* OXYGEN *and* OXIDATION.

Oxidising Agents (*Chem.*) *See* OXIDATION.

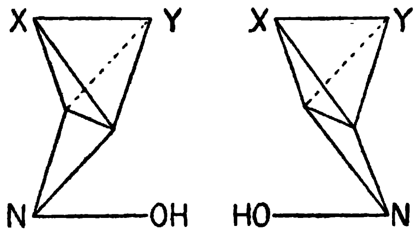
Oximes (*Chem.*) Compounds containing the group $>C = NOH$. There are two classes of oximes, one class derived from aldehydes, and the other from

ketones; the former class is distinguished by the name Aldoximes, and the latter by the name Ketoximes.

$$\underset{\text{Acetaldehyde.}}{\begin{array}{l}CH_3\\ |\\ HC=O\end{array}} + H_2N.OH = \underset{\text{Acetaldoxime.}}{\begin{array}{l}CH_3\\ |\\ HC=NOH\end{array}} + H_2O$$

$$\underset{\text{Acetone.}}{\begin{array}{l}CH_3\\ CH_3\end{array}\!\!>CO} + H_2NOH = \underset{\text{Acetoxime, a Ketoxime.}}{\begin{array}{l}CH_3\\ CH_3\end{array}\!\!>C=NOH} + H_2O$$

Oximes are usually obtained by acting on the aldehyde or ketone with hydroxylamine hydrochloride in presence of caustic soda. When that carbon atom in an oxime which is doubly linked to nitrogen is united to two different groups, one of which may be hydrogen, stereoisomerism may arise. The isomers in the case of a monoxime may be represented thus:



In what follows this will be represented for short as:

$$\text{I.}\quad \begin{array}{c}X-C-Y\\ \ddot{N}-OH\end{array} \qquad \text{II.}\quad \begin{array}{c}X-C-Y\\ HO-\ddot{N}\end{array}$$

For example, acetaldoxime should exist in two forms:

$$\underset{\text{Synacetaldoxime.}}{\begin{array}{c}\\ \ddot{N}-OH\end{array}} \qquad \text{II.}\ \underset{\text{Antiacetaldoxime.}}{\begin{array}{c}CH_3-C-H\\ \|\\ HO-\ddot{N}\end{array}}$$

Form I. is called the Syn form, and Form II. is called the Anti form. Both forms are known in many cases both of Aldoximes and Ketoximes. Acetaldoxime is known as a solid which melts at 47°, and is transformed by heating it to 100° into the other form, which melts at 12°. The latter form is unstable, and passes on keeping into the higher melting variety. Benzaldoxime, when formed by the method given above, exists in the anti form (*see* below); but the syn form can be obtained from it by dissolving in benzene, passing in dry hydrogen chloride, and decomposing the hydrochloride so formed by sodium carbonate. The anti and syn forms of benzaldoxime melt respectively at 49° and 81°. The syn is the stable form for fatty aldoximes, and the anti for aromatic aldoximes. On looking at the formulæ for the syn and anti acetaldoximes given above, it will be seen that the syn form of any aldoxime should more readily lose the elements of water than the anti form. Accordingly, where the two forms are known, that one which loses water more readily is regarded as the syn form. Example: When the two forms of benzaldoxime are cautiously dissolved in acetic anhydride, they form acetates. The acetate of the syn form easily decomposes into benzonitrile and acetic acid on treating with sodium carbonate, the nitrile separating as an oil, while the acetate of the anti form dissolves.

$$\begin{array}{c}C_6H_5-C-H\\ \ddot{N}-OH\end{array} \qquad \begin{array}{c}C_6H_5-C-H\\ \ddot{N}O.OC.CH_3\end{array} \qquad \begin{array}{c}C_6H_5-C\\ \dddot{N}\end{array} + CH_3COOH.$$

$$\begin{array}{c}C_6H_5-C-H\\ \|\\ HON\end{array} \rightarrow \begin{array}{c}\\ \|\\ CH_3.CO.ON\end{array} \rightarrow \text{No decomposition.}$$

As acetates cannot be isolated in the case of the fatty aldoximes, it must be concluded that they usually exist in the syn form, producing an acetate first which is so unstable that it instantly decomposes into nitrile and acetic acid. The ketoximes undergo the Beckmann rearrangement. Example:

$$\underset{\text{Benzophenone Oxime.}}{\begin{array}{c}C_6H_5-C-C_6H_5\\ \ddot{N}-OH\end{array}} \rightarrow \begin{array}{c}C_6H_5-C-OH\\ \|\\ N-C_6H_5\end{array} \qquad \underset{\text{Benzanilide.}}{\begin{array}{c}|\\ NH.C_6H_5\end{array}}$$

This reaction can be used to distinguish between the syn and anti ketoximes. It is brought about by the action of strong acids, acid chlorides (which also yield some acid ester), glacial acetic acid, acetic anhydride, and hydrogen chloride; best of all by dry ether and phosphorus pentachloride. Example of its use in determining configuration is:

$$\underset{\text{Paramethoxybenzophenone (MP 115°).}}{\begin{array}{c}C_6H_5-C-C_6H_4OCH_3\\ \|\\ N-OH\end{array}} \rightarrow \begin{array}{c}C_6H_5-C-OH\\ \|\\ \end{array} \rightarrow \underset{\text{Benzoic Acid Aniside.}}{\begin{array}{l}C_6H_5-CO\\ |\\ NHC_6H_4OCH_3.\end{array}}$$

$$\underset{\text{Paramethoxybenzophenone (MP 137°).}}{\begin{array}{c}C_6H_5-C-C_6H_4OCH_3\\ \|\\ HON\end{array}} \rightarrow \begin{array}{c}HO-C-C_6H_4OCH_3\\ \|\\ C_6H_5.N\end{array} \rightarrow \underset{\text{Anisic Acid Anilide.}}{\begin{array}{l}OC-C_6H_4OCH_3\\ |\\ C_6H_5HN\end{array}}$$

For further information see Werner's "Stereochemie." Oximes are resolved by aqueous acids into their components:

$$(CH_3)_2C:NOH + H_2O = (CH_3)_2CO + H_2NOH.$$

Reduction by hydrogen (sodium amalgam and glacial acetic acid) converts them into amines:

$$(CH_3)_2C:NOH + 4H = (CH_3)_2CHNH_2 + H_2O.$$

The following is an important application of an oxime in the chemistry of the sugars: Glucose yields an oxime by direct reaction with a pure solution of hydroxylamine. On treating this oxime with acetic anhydride and sodium acetate, the penta acetate of the nitrile of d-gluconic acid is obtained. This nitrile loses its cyanogen group on treatment with ammoniacal silver oxide. The product on hydrolysis with hydrochloric acid gives d-arabinose—a pentose:

$$\underset{\text{d-Glucose Oxime.}}{CH_2OH(CHOH)_4CH:NOH} \rightarrow$$

$$CH_2OOCCH_3(CHOOCCH_3)_4CN \rightarrow$$

$$\underset{\text{d-Arabinose.}}{CH_2OH(CHOH)_3CHO.}$$

The formation of oximes is important in characterising aldehydes and ketones.

Oxindole (*Chem.*) $C_6H_4<\genfrac{}{}{0pt}{}{^{1}CH_2}{^{2}NH}>CO$. Tautomeric form, $C_6H_4<\genfrac{}{}{0pt}{}{CH}{N}\!=\!COH$. The lactam of orthoaminophenylacetic acid. Crystallises in needles; melts at 120°; soluble in water; oxidises in moist air to dioxindole, $C_6H_4<\genfrac{}{}{0pt}{}{CHOH}{NH}>CO$; reduces ammoniacal silver; heated with baryta water at 150°, it gives the barium salt of orthoaminophenylacetic acid: nitrous acid gives an isatine oxime, $C_6H_4<\genfrac{}{}{0pt}{}{C:NOH}{NH}>CO$; it easily forms a potassium salt, which with ethyl-iodide and subsequent hydrolysis yields ethylorthoaminophenylacetic acid, showing that in the potassium salt the metal is united to nitrogen. Oxindole is obtained by reduction of orthonitrophenylacetic acid by tin and hydrochloric acid.

Oxonium Compounds (*Chem.*) In certain of its compounds oxygen appears to have marked basic properties; in such compounds the oxygen is divalent, but it can unite with acids and form salts in which the oxygen behaves as a tetravalent element. These salts of tetravalent oxygen are called oxonium compounds, from analogy with ammonium compounds:

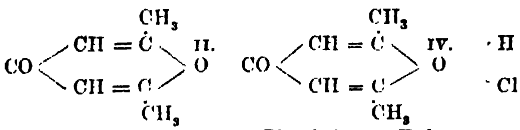
$$\genfrac{}{}{0pt}{}{R}{R_1}>\overset{\text{II.}}{O} \qquad \genfrac{}{}{0pt}{}{R}{R_1}>\overset{\text{IV.}}{O}<\genfrac{}{}{0pt}{}{H}{X}$$

Oxonium Compound.

$$\begin{array}{l}R\\R_2\end{array}>\overset{\text{III.}}{N} \quad > \quad \begin{array}{l}R\\R_1-\\R_2\end{array}\overset{\text{V.}}{N}<\genfrac{}{}{0pt}{}{H}{X}$$

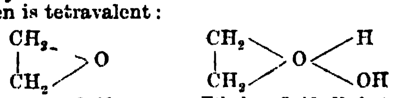
Ammonium Compound.

Examples: Dimethyl pyrone forms salts with many acids, and behaves like a base comparable in strength to a weak base like urea:



Dimethyl Pyrone. Dimethylpyrone Hydro[chloride]

The discovery of the quadrivalence of oxygen in salts of dimethyl pyrone (Collie and Tickle) has led to the recognition of the quadrivalence of oxygen in a large number of organic compounds. Thus an aqueous solution of ethylene oxide precipitates many metals as hydroxides from solutions of their salts, and this is best explained by assuming a compound of ethylene oxide and water to be formed in which oxygen is tetravalent:



Ethylene Oxide. Ethylene Oxide Hydrate.

Ether, acetone, and many alcohols have the property of uniting with acids to form compounds in which the oxygen of the substances mentioned is tetravalent. It is remarkable that complex acids, such as hydroferrocyanic, hydroferricyanic, phosphotungstic, and others seem especially prone to form oxonium salts. The oxonium salts of certain colourless or feebly coloured substances are strongly coloured compounds, and to this phenomenon the name halochromie has been given. Examples are: (1) Dibenzalacetone:

$$\genfrac{}{}{0pt}{}{C_6H_5CH=CH}{C_6H_5CH=CH}>CO$$

a pale yellow solid whose hydrochloride is intensely yellow and hydriodide nearly black. (2) Triphenylcarbinol:

$$\begin{array}{l}C_6H_5\\C_6H_5-\\C_6H_5\end{array}>C.OH$$

a colourless crystalline solid which dissolves in concentrated sulphuric acid with an intense yellow colour.

Oxybaphon (*Archæol.*) A large bell shaped vessel like the Crater, used by the Greeks and Romans for holding wine.

Oxychlorides (*Chem.*) *See* CHLORIDES.

Oxy-Compounds (*Chem.*) These are better called hydroxy-compounds. *See* HYDROXY.

Oxy-Ether Light A substitute for the oxyhydrogen light where coal gas and hydrogen are not available. A stream of oxygen is blown through a tank of ether, and the mixture burnt along with an additional supply of oxygen at the jet. *See* OXY-HYDROGEN FLAME.

Oxy-Gaslight. Coal gas may be used with oxygen under pressure instead of hydrogen. The blow-through jet is used in this case. *See* OXYHYDROGEN FLAME.

Oxygen (*Chem.*), O. Atomic weight, 16. A faintly blue, odourless gas; it is magnetic; boils at − 182°, the liquid is distinctly blue; 1 litre at 0° and 760 mm. weighs 1·43 grs.; 100 cc. water at 0° dissolve 4·9 cc. oxygen at 0° and 760 mm. Oxygen occurs free in the air to the extent of very nearly 21 per cent. by volume or 23 per cent. by weight, when determined after the air has been freed from water vapour and carbon dioxide. As oxygen is dissolved by water it also occurs free in all natural waters. This free oxygen is necessary for the respiration of all plants and animals. Oxygen occurs combined in water (⅞ by weight) and in silica, carbon dioxide, all tissues of plants and animals. It has been calculated that the weight of the atmospheric oxygen on every square centimetre of the earth's surface is about 234 grams, while the same amount of oxygen is contained in a layer of water 260 cm. deep and 1 square centimetre area, while the oxygen in the earth's solid crust is about 10,000 times that in the air. Oxygen may be obtained by heating many oxides, *e.g.* those of mercury, silver, and gold, and all peroxides of metals; also by heating salts of oxy-acids rich in oxygen, such as chlorates, permanganates, perchlorates; by heating peroxides, permanganates, dichromates with sulphuric acid; by the electrolysis of acidulated water, or water made alkaline with caustic potash or baryta water, when the oxygen is evolved at the positive pole; by warming a paste of bleaching powder and water with a cobalt salt. On the large scale it is obtained from the air by Brin's Process (*q.v.*) Oxygen unites directly with most of the other elements: with some, such as phosphorus, sodium, potassium, calcium, at the ordinary temperature; with others on heating, such as carbon, zinc, copper, iron, lead; it does not unite directly with the halogens and the noble metals (silver, gold, platinum). The rate of union depends

on the state of division of the element. Oxidation proceeds so quickly with finely divided iron and lead that they catch fire in air at the ordinary temperature when sufficiently finely divided. All ordinary combustions are due to the union of the oxygen of the air with the thing burned or with the constituent elements of the thing burned, as when coal gas burns; here the free hydrogen unites directly with the oxygen of the air, while the elements of the marsh gas which is contained in coal gas each unite separately:

$$CH_4 + 2O_2 = CO_2 + 2H_2O.$$

As air contains only one-fifth of its volume of oxygen, all substances which burn in air burn much more rapidly, and therefore at a much higher temperature and much more brightly in oxygen. When an element can unite with oxygen in more than one proportion the compound formed by the union of the two will depend on the relative amount of the element and oxygen; thus copper and phosphorus each form lower oxides with a restricted supply of oxygen than they do with a free supply of oxygen. In the case of compounds also the products are usually different when combustion occurs in a restricted supply of oxygen from what they are in a free supply. Sulphuretted hydrogen in a restricted supply of oxygen gives water and sulphur; in a free supply, water and sulphur dioxide. Marsh gas can be made to yield methyl alcohol, formaldehyde and formic acid in a limited supply of oxygen; but in a free supply it yields carbon dioxide and water only. Finally, many, if not all, combustions in oxygen do not occur in the absence of every trace of moisture; carbon monoxide, nitric oxide, phosphorus are examples of substances which will not unite with oxygen in absence of moisture. Oxygen is distinguished from all other gases except nitrous oxide by rekindling a glowing spill, and from all other gases by giving reddish brown fumes with nitric oxide and by turning an alkaline solution of pyrogallic acid brown or an ammonia solution of cuprous oxide blue. Oxygen has the property of uniting with certain compounds of unsaturated character to form unstable substances which possess active oxidising properties. The oxygen united in this way is called "active oxygen," and the process of union is called the "activising" of oxygen. Thus turpentine is a substance which renders oxygen "active." The compounds are supposed to be formed by the addition of a molecule of oxygen, and they have been called "moloxides." The oxygen in these moloxides can oxidise a portion of the unactivised compound, or it can oxidise other substances capable of oxidation when brought in contact with the moloxide. Thus active turpentine oxidises water to hydrogen peroxide; potassium iodide with liberation of iodine, many metals, and indigo solution. One of the best established cases besides turpentine is triethylphosphine:

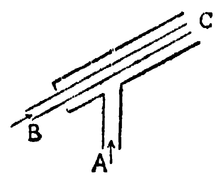
$$(C_2H_5)_3P + O_2 = (C_2H_5)_3P\left\langle\begin{matrix}O\\ |\\ O\end{matrix}\right.$$

The triethylphosphine moloxide can yield triethylphosphine oxide by autoxidation, or it can oxidise another substance such as indigo:

$$(C_2H_5)_3P + (C_2H_5)_3P\left\langle\begin{matrix}O\\ |\\ O\end{matrix}\right. = 2(C_2H_5)_3PO.$$

See OXIDATION.

Oxyhydrogen Flame and Light. Hydrogen burns in air with a non-luminous but hot flame; if the flame be supplied with oxygen instead of with air, a still hotter flame results; the temperature of the flame is sufficient to melt many very refractory substances, *e.g.* quartz and platinum; while certain infusible bodies, such as lime, are raised to a state of brilliant incandescence. Ordinary coal gas gives a flame which is nearly equal to that obtained from pure hydrogen, and may frequently be used instead. For burning coal gas, or hydrogen supplied at low pressures, a BLOW THROUGH JET is generally used: a typical form is shown in the figure. The hydrogen or coal gas enters at A, and burns at the open end of the jet C; here it is fed by a steady stream of oxygen flowing through the central tube B. The form of the mouth C is modified in various ways, but the essential principle remains the same.



When the two gases are obtainable under approximately equal pressures, as, for example, when both are supplied in steel cylinders, a MIXING JET is used. In this case the hydrogen and oxygen are allowed to mix in proper proportions in a small chamber, from which a single tube leads to the jet. If the gases are allowed to mix in exactly their combining proportions (two volumes of hydrogen to one volume of oxygen), there is great risk of explosion, though in a good mixing jet this may lead to no worse result than the "snap" which causes a sudden extinction of the flame. But by using a considerable excess of hydrogen, the arrangement is safe and the flame steady and far more powerful than when the gases are in their combining proportions. The OXYHYDROGEN LIGHT or LIMELIGHT is obtained by allowing the flame to impinge on the surface of a small cylinder of lime (calcium oxide, CaO). This cylinder is usually about 2 in. high and 1 in. in diameter; a hole is bored along its axis through which passes a rod which supports the lime. By means of this rod the lime can be raised and lowered, or turned round, so that a fresh surface can be exposed to the action of the flame.

Oxy-Spirit Light. When coal gas or hydrogen is not available, its place may be supplied by the vapour of METHYLATED SPIRIT (*q.v.*), burnt at a jet resembling that used in the oxyhydrogen light and supplied with oxygen under pressure. *Cf.* OXYHYDROGEN FLAME.

Ozokerite (*Chem.*) A soft yellowish solid which occurs in the ground chiefly in Galicia and Roumania. Its constitution is unknown, but it is probably a hydrocarbon or mixture of hydrocarbons of the olefine series. When bleached it is used under the name of cerasin or ceresine (*q.v.*) as a substitute for beeswax.

—— (*Min.*) One of the hydrocarbons. It is a solid, of a dark brownish colour, resembling wax, and melting at 130° to 140° F. When refined, it yields CERESINE (*q.v.*) From Uphall in Linlithgowshire, Newcastle, Galicia, Moldavia, etc.

Ozone (*Chem.*), O_3. A faint blue gas which has not been obtained free from oxygen; has characteristic smell. The liquid gas is deep blue and very magnetic; it boils at −119° to −125°. The liquid is explosive. It is absorbed by many essential oils, such as turpentine; slightly soluble in water. The gas is easily decomposed by heat into oxygen. On account of the ease with which it gives up one atom

of oxygen and passes into ordinary oxygen it has strong oxidising properties, *e.g.* it oxidises many metals. In the case of mercury a mere trace of ozone is enough to destroy the surface tension of a large quantity of the metal; also many lower oxides are changed by it to higher oxides, many sulphides to sulphates. It oxidises and destroys organic matter so that ozone cannot occur in air which contains much organic matter. It reacts with potassium iodide as follows:

$$2KI + H_2O + O_3 = 2KOH + O_2 + I_2.$$

Here, since a molecule of ozone gives rise to a molecule of oxygen, there is no change of volume. This reaction also serves as a test for ozone when it is known that no other substance such as chlorine is present which can liberate iodine from potassium iodide. Ozone probably occurs in very pure air; it does certainly after the occurrence of electric discharges. It is formed in a large number of processes, *e.g.* in the electrolysis of acidified water, in the silent electric discharge by the kathode rays, and by radium rays; also when moist phosphorus is exposed to air, when sulphuric acid acts on peroxides, permanganates, etc. To obtain it in quantity the silent discharge is passed across a thin layer of oxygen at a low temperature. That ozone has the formula O_3 is shown by weighing a vessel full of oxygen, then weighing the same vessel full of ozonised oxygen, and finding the volume of the ozone in the latter case by absorbing it with turpentine. The difference in weight is the difference between the weight of equal known volumes of oxygen and ozone; and as the density of oxygen is known, that of ozone becomes known. Experiment gave density = 47·8. Ozone is used in the purification of drinking water. Experiments have shown that by combined filtration and ozonisation the number of microbes can be reduced from 100,000 to 600,000 per cubic centimetre of water down to at most 2 to 9 per cubic centimetre. It is also used as a disinfectant in other ways: in bleaching, in oxidising oils, etc. A solution in olive oil is sold under the name "Electron."

Ozonometer (*Meteorol.*) An apparatus which by the use of ozone test papers determines the amount of ozone in the atmosphere.

Ozotype (*Photo.*) The name given to a modified form of carbon printing by the inventor Mr. T. Manly. In this process the print is made upon sized paper sensitised with a mixture of a bichromate salt, manganous sulphate, etc., and when sufficiently printed the unaltered salts are removed by washing in cold water. This initial image forms the basis upon which the finished print is afterwards formed in pigmented gelatine. In this process no reversal of the image occurs.

P (*Chem.*) The symbol for PHOSPHORUS (*q.v.*)

π. The symbol used for the ratio of the circumference to the diameter of a circle; the number 3·1416.

Pacinotti Ring (*Elect.*) An early form of dynamo armature, ring shaped, and provided with projecting teeth.

Packing (*Eng.*) (1) Material placed in a cavity or STUFFING BOX (*q.v.*), through which a piston rod passes, in order to make a steam-tight joint. (2) Material of any kind, *e.g.* wooden blocks, used to raise an object by a small amount.

Packing (*Mining*). A Cornish term for the final dressing of copper or tin ore.

Packing Case. A large box, usually of unplaned timber, with the joints nailed together instead of being dovetailed; often lined with lead, zinc, etc.

Packing Ring (*Eng.*) A PISTON RING (*q.v.*)

Pad (*Build.*) A piece of lead or felt placed under the ends of a steel girder at its bearings.

—— (*Engrav.*) An implement shaped at the base like a broad pestle, and consisting of some soft material covered with silk. It is used for spreading the warm varnish over plates that are to be etched. *See also* ENGRAVING AND ETCHING.

Padding. Superfluous matter in a literary article, speech, periodical, etc., introduced for the purpose of filling up space. Superfluous accessories which detract from the merit of an artistic composition.

Paddle (*Eng., etc.*) (1) One of the blades fixed on the paddle wheel (*q.v.*) of a steamship; more correctly termed a FLOAT. (2) A tool used for spreading various kinds of material in metallurgy, paint mixing (*q.v.*), glass manufacture, brickmaking, etc. (3) A sluice in a lock-gate, or in a weir, for regulating the quantity of water passing through.

Paddle Boat (*Eng.*) A steamboat propelled by Paddle Wheels (*q.v.*); now almost superseded by the use of the Screw Propeller (*q.v.*)

Paddle Box (*Eng.*) The casing over the upper part of a Paddle Wheel (*q.v.*)

Paddle Wheels (*Eng.*) A pair of wheels of large diameter. On the circumference are fixed flat FLOATS, projecting in a radial direction. Paddle wheels were used on all the early types of steamship, but they are now nearly obsolete. The floats were either fixed or else hinged at their base, and actuated by levers in such a way that they entered the water at right angles to the surface; the latter type are termed FEATHERING FLOATS.

Paddling (*Leather Manufac.*) A process of tanning light skins in a pit in which a paddle revolves. The paddle keeps the skins and tan liquor gently moving, and so accelerates the process.

Pad Saw (*Joinery*). A narrow saw that will slip inside the handle (pad) when not in use.

Page Cord (*Typog.*) Small, strong twine with which the pages of type are tied round to secure them temporarily until they are imposed.

Page Gauge (*Typog.*) A narrow piece of wood technically known as reglet, and rather longer than a page of the work to be printed. It is notched at a point where the full page of type, including head and signature line, ends. The purpose is to secure uniform length of pages and to facilitate imposition.

Pagoda (*Architect.*) (1) A Hindoo temple. (2) The lofty, many storied Chinese and Japanese towers are known as Pagodas and also as Taas.

Paint (*Dec.*) A liquid or semi-liquid consisting of one or more pigments reduced to a fine powder and mixed with linseed oil and turpentine or other vehicle (*see* THINNERS), and intended to be used for the preservation or beautifying of the surface to which it is applied. A second class of paints are known as "water paints" (*q.v.*), and require only the addition of water to render them ready for

use. Most paints are made from a base such as white lead, oxide of zinc, lithopone, barytes, or some other white pigment (*see* PIGMENT) mixed with colouring matter in order to produce the required hue. Sometimes a base of an earth colour such as ochre or sienna is used in place of the white. *See* PAINT MIXING. The term "pure paint" is a misnomer, since any mixture of pigments and drying oils would form a paint; in fact, if ordinary road mud were dried, ground in oil, and then thinned with oil and turpentine, it might be said to be a pure paint. When the word "paint" is used in connection with the name of a pigment of well defined composition, it causes vagueness and uncertainty. For example, "white lead" on a package means that the contents consists wholly of white lead or basic carbonate of lead; but if the term "white lead paint" is employed, it indicates a paint, in the composition of which only a certain amount of white lead has been used.

Painters' Brushes (*Dec.*) The brushes with which the painter, the decorator, and the artist apply paint in the execution of their work vary largely in shape, size, and make, scores of different kinds being used according to the exact requirements of the work in hand. They all consist essentially of some sort of flexible bristles, hairs, or fibres, held together by means of twine, wire, or metal bands, and fixed to a suitable handle. The best painters' brushes, which are intended to be used in oil paint, are made of hog's bristles of various kinds, intermixed so as to give "spring" or elasticity, solidity, and strength. These bristles are very expensive, and in the cheaper brushes it is common to find horse hair and other adulterants mixed with them. The result is that the brush is flabby, lacks spring, and does not last long. Genuine bristles can be recognised when viewed under a magnifying glass by their having split ends, while the root will be found to be "flagged," *i.e.* larger than the stem. Horsehair and fibre have both ends alike and of the same size. GROUND BRUSHES are used to apply paint to fairly large surfaces, and are made in different shapes, the chief being the ordinary "round" and "oval" forms. The latter is generally thought to be handier to use than the round form. Ground brushes are made in eight sizes, varying in the weight of bristles from 1 oz. to 8 oz., and usually numbered 1/o to 8/o. The smallest and largest sizes are not much used. The smaller brushes are called SASH TOOLS, and are used in cases where the ground brush is too bulky; for example, on mouldings, sashes, beads, etc. For executing narrow lines and in painting the smallest details, FITCHES are employed. These consist of smaller bristles, formed to make a flat, pointed tool, and held in place by a metal ferrule on the end of a somewhat long handle. "LINERS" are used for drawing lines in paint upon work. They are made with square and bevelled edges, and the bristles are quite stiff. VARNISH BRUSHES are specially made for applying varnish, although some makes are suitable for both paint and varnish. They are flat in form, and the bristles usually taper to form a bevelled edge. This is effected by standing the bristles in a little box with a convex bottom, formed of the same shape as that which it is desired the ends shall assume. DISTEMPER BRUSHES are made in various forms, the most common being termed "one knot," "two knot," and "three knot." The term "knot" means that a bunch of the hair is tied up with wire. The handles are usually made of beechwood. Another form which is rapidly growing in favour is made by binding the bristles in flat form to the stock or handle, either by brass, tin, or leather. DUSTING BRUSHES, as the name implies, are used for removing dust, etc., from a surface before the paint is applied. They consist of long, elastic bristles, somewhat loosely bound, and are made in two forms—round (used in London and the south of England); and flat (used almost exclusively in the north). The latter possesses the advantage that it may be used for removing dust from places where the round brush would not go, *e.g.* between the balusters on a staircase. STIPPLERS are large, flat, square brushes having a handle on the back, and are used for stippling paint work, *i.e. dabbing* a newly painted surface so as to remove brush marks and leave a slightly uneven surface. *See* STIPPLING. STENCIL brushes are usually stiff bristled tools, held together in a tin ferrule or twine binding, and are used both in oil and water paint. *See* STENCILLING. Various additional brushes are used by grainers and sign writers. *See* SIGN WRITING. Ordinary painters' brushes, such as ground brushes and sash tools, when new are too long in the bristles for convenient use, and are therefore "bridled," *i.e.* bound up about halfway with cord. Bridles are sold ready for use, but practical painters usually prefer to make them on the brush. In some makes of brush a small piece of copper wire is bound in with the bristles at each side, so as to be bent back, and form holds for the twine used in forming the bridle. In others two little metal eyelet holes are provided for the same purpose. In all cases the bridle is removed when the bristles have become sufficiently worn to render its further use unnecessary. The care of brushes is of great importance, and yet is frequently neglected. Paint brushes after use should be thoroughly cleansed with turpentine or soap and water, all paint being removed, and should then be wrapped up in paper, with a little camphor or naphthalene to keep away moth, and put away until required in a fairly cool dry place. If, however, the brush is required for use the next day, it is not necessary to take this trouble. It should then be suspended in a can or other suitable utensil full of raw linseed oil, or water may be used instead. The brush should not stand on the bristles, or the weight will cause them to turn to one side, and the brush will remain permanently out of shape. A hole bored through the handle of the brush, and a wire or thin rod passed through it, forms a simple but effective device for the purpose. Varnish brushes are usually suspended in linseed oil, but never water. A better plan is to suspend them in varnish, and in cases where the work is of a delicate character in the same grade of varnish as that in which the brush is used. In this case it is necessary to use a special can having an airtight cover. Whitewash, distemper, and all other brushes used in water need only cleansing, but they must never be put away damp or be stored in a very warm and dry place, or the bristles are likely to become loose. In every case it is best to soak a brush of this kind in water for a couple of hours before using it. Writing pencils should be cleaned in turpentine, and, if they are not to be used for some time, dipped in olive oil or tallow and smoothed out to a point. Brushes that have become hard with paint should be soaked in a liquid paint remover, such as Ball's, or in raw linseed oil, and may then be cleaned with hot turpentine. No brush should be kept in turpentine for a length of time, as it causes the bristles to lose their elasticity. Water has the same effect.—A. S. J.

Painters' Holiday (*Dec.*) A term used to indicate portions of painted work which have been inadvertently skipped or missed. To prevent this it is usual to vary the colour of undercoats somewhat, so that the portions of the surface reached by the paint brush can be distinctly seen.

Painting (Methods). In the history of the technical processes used by the painter the first place must be given, on the ground of antiquity, to what is known as PAINTING IN TEMPERA. This method was followed in remote ages by the decorators of Egypt, Assyria, and of other Eastern countries, as well as by the Greeks and early Italians, and is still counted among the accepted modes of pictorial practice. It is in its mechanism akin to both oil and water colour painting, but it has certain peculiar qualities by which it is distinguished. The colours employed are certain earths and other dry pigments which are made to adhere to the canvas or wall surface by being mixed with a gummy medium such as glue, size, white or yolk of egg, starch, milk, cheese, the juice of the fig tree, or a compound made up of several of these combined. The process is susceptible of many applications and does not limit the artist who uses it to a particular manner of expression. Its results are permanent under proper conditions, and the works for which it has been employed are not seriously liable to chemical change or mechanical disintegration. FRESCO in its various forms has also a history of many centuries. It was much practised in Italy, both in Roman times and during the period of the Renaissance, and its best traditions are still kept up by modern artists in that country. True fresco is a method of painting upon wet plaster with colours mixed with water. These soak into the actual substance of the plaster and become permanently incorporated with it as it dries. Only those pigments which do not suffer from contact with lime can be used, and only so much of the plaster surface as will remain wet while the artist is painting on it can be dealt with in each day's working. An ancient variation of true fresco was used by the Romans. It was called ENCAUSTIC PAINTING, and its peculiar qualities came from the use of wax for a binding medium. Wax was applied to the plaster as a ground, it was often mixed with the pigments themselves, and was finally spread over the face of the finished painting, and then by the application of heat was fused into a solid mass in which the colours were securely locked up and protected from all possibility of damage by atmospheric influences. A modern method, known as SPIRIT FRESCO, also depends upon the use of wax to bind the work together. In this the wax is dissolved in a volatile oil, and the resulting compound is employed as a medium for preparing the wall surface and for mixing with the pigments, so that a fusing effect akin to that in encaustic painting is produced without the use of heat. In another modern variation, WATER GLASS PAINTING, the pigments, mixed with water, are laid upon plaster which has been previously soaked with solutions of ferro-silicic acid and water glass of potassium, and they are set with a fixative which is sprayed or brushed over them after they have dried. All kinds of fresco depend greatly for their permanence upon protection from moisture, and they are easily destroyed by damp soaking into the wall on which they are painted. OIL PAINTING began to be extensively practised towards the end of the fifteenth century. According to tradition it was invented by Van Eyck, a Flemish artist, but its principles were understood at an earlier date, and he seems merely to have systematised them conveniently. It differs from tempera painting chiefly in the substitution of oil or varnish in the place of the albumen or size chosen as the binding medium in the older process. The pigments are mixed with oil and varnish until they become of the right working consistency, and are laid upon canvas, wood panels, or any other equally convenient surface. Under reasonable conditions oil paintings will last for centuries, but they are liable to changes in tone from the darkening of the oil vehicle and to colour alterations from the use of fugitive pigments. The technicalities of the process are, however, so adaptable and so easily controlled that its popularity is quite intelligible. Modern WATER COLOUR PAINTING in its best form is a process of staining white paper with washes of transparent colour. The pigments are soluble in water, but they are prepared with the admixture of a small amount of gummy medium which makes them flow more easily over, and adhere more closely to, the surface of the paper. Work done in transparent water colour is brilliant in effect and full of variety, both of colour and tone, and as the white paper shines through the washes it has a pleasantly luminous quality. Some artists prefer to make their water colours opaque by mixing Chinese white with the transparent colours, and by so doing revert more or less to the practice of the tempera painters ; but the best results are obtained by what is commonly considered to be the more legitimate method of transparent painting. One other technical device must be noted—PASTEL PAINTING. This is really a method of drawing in colours, for the pigments are compressed into sticks with so little binding medium that they work like soft chalk and are made to adhere to paper or canvas merely by the pressure of the hand in drawing. The results attained by such a process are necessarily somewhat fragile, but yet pastel paintings, if they are protected from friction or rough usage, are quite permanent. They do not undergo any chemical changes and are not liable to fade or become discoloured. This method of painting was first used in France in the seventeenth century, and its suitability for pictures of a delicate and fanciful type has made it widely popular with artists. It is still very generally practised.—A. L. B.

Painting, Schools of. The nature of the works achieved by the ancient schools of painting cannot be very exactly estimated. That the Egyptians and the Assyrians were skilful decorators and studied closely some of the best principles of pictorial art can be judged from existing remains, but these remains give a more or less imperfect idea of the full scope of their practice. Tradition assigns to the Greeks also considerable proficiency in painting, but none of their pictures have survived; and of Roman art there have been preserved only examples of mural decoration. Some of these have certainly a freshness of design and a beauty of finish which suggest that the technicalities of painting were well understood by the artists of the period. The knowledge of drawing and the appreciation of colour combination displayed in them imply the existence of high standards of accomplishment and the observavance of well established artistic traditions, so that there was not improbably a fair number of able painters among the Romans. But the real history of painting with which we are concerned began in

the thirteenth century, when Cimabue laid the foundations of the great ITALIAN SCHOOL. This school can be divided into several groups, in each of which there were men who may be placed among the great masters of the world. There were the Tuscans and Florentines, with Giotto (1276–1336), Masaccio (1402–1428), Leonardo da Vinci (1452–1519), and Michael Angelo (1475–1563) as leaders in a company which included also Botticelli, Andrea del Sarto, Luca Signorelli, Filippo Lippi, Sodoma, and Bronzino; there was the Umbrian group, with Perugino (1446–1524) and Raphael (1483–1520), and others like Pinturicchio and Giulio Romano; the Paduan group, with Mantegna (1431–1506), Squarcione, and Schiavone; the Veronese group, headed by Paolo Veronese (1530–1588); and the Lombardy group, with such masters as Domenichino, Guido, Parmigiano, Correggio, and the Carraccis. There was, too, the splendid Venetian school, which began its great career in the fifteenth century with John Bellini (1426–1516), and produced in the years that succeeded Titian (1477–1576), Giorgione (1478–1511), Tintoret (1512–1594), and others like Sebastian del Piombo, Bordone, and Moroni. Altogether the glorious period of Italian art covered nearly four hundred years. Meanwhile there was growing up in the Low Countries another school which was destined to become not less famous. It was made up of two groups, the FLEMINGS and the DUTCHMEN. In the first were included Hubert Van Eyck and Jan Van Eyck, both born towards the end of the fourteenth century; Hans Memling, who flourished in the fifteenth century; Quentin Matsys and Mabuse, who carried on the traditions of the school into the sixteenth century; Rubens, who was born late in the sixtenth century and died in 1640; and Van Dyck (1599–1641). The Dutch masters belong almost entirely to the seventeenth century; among them were Hals (1584–1666), Rembrandt (1607–1669), Terburg (1607–1669), Teniers (1610–1694), and others like Cuyp, Paul Potter, Ostade, Hobbema, and Bol. In the latter part of the fifteenth century and the early part of the sixteenth there were some GERMAN ARTISTS of note—Martin Schongauer, Lucas Cranach, Aldegrever, and Hans Holbein, who died in England in 1543 or 1554. The SPANISH SCHOOL owes its reputation chiefly to the fact that it produced one great master, Velasquez (1599–1660). His contemporaries—Zurbaran, Ribera, and Murillo—were also artists of distinguished capacity, but none of them can be said to have quite rivalled him in power. About a century after Velasquez appeared Goya (1746–1828), who is entitled to a place among the more notable Spanish painters. The FRENCH SCHOOL has a long and honourable record. Its best period began with Nicholas Poussin (1594–1665) and Claude (1600–1682); and in the early eigteenth century it included many men of admirable skill, among them Watteau (1684–1721), Lancret (1690–1743), Chardin (1699–1779), Boucher (1704–1770), Greuze (1725–1805), and Fragonard (1732–1806). A little later came others like David, Delaroche, Gericault, and the Vernets, who helped on appreciably the development of the school in its modern form. The ENGLISH SCHOOL had its real beginning with William Hogarth (1697–1764). There had been artists of native birth before him, but none of them can be said to deserve places in any list of masters. The immediate successors of Hogarth were, however, men of unquestionable importance. Sir Joshua Reynolds (1723–1792), Thomas Gainsborough (1727–1788), George Romney (1734–1802), John Hoppner (1768–1816), Sir Henry Raeburn (1756–1823), and Sir Thomas Lawrence (1769–1830) are all counted now as superlatively accomplished painters of portraits and figure subjects, and J. M. W. Turner (1775–1851) and John Constable (1776–1837) as landscape painters of supreme ability. The English water colour school, too, which came into existence about the middle of the eighteenth century, quickly made a reputation by the power of the men who attached themselves to it and the excellence of the work they produced. The modern schools which have at the present time the fullest vitality are the French, the English, and the Dutch. France is still a centre where the science of painting is admirably understood, and where fine craftsmen abound. In England the older traditions, though modified to some extent by foreign influences, are being soundly carried on; and in Holland a new form of artistic sentiment, derived chiefly from France, has been very successfully grafted on to the sturdy and masculine art of the older Dutch masters. In Italy and Spain there are some skilful executants but hardly any artists of the first rank; and the same may fairly be said of Germany.—A. L. B.

Paint Mixing (*Dec.*) The method of mixing paints and colours employed by painters is a somewhat crude one. A little oil is first placed in a can or paint pot to prevent sticking, and then the base or principal pigment, *e.g.* white lead, zinc white, ochre, etc., ground in oil, is placed in the can, and linseed oil and turpentine are added slowly, together with the necessary quantity of driers (*q.v.*) The pigment is beaten against the side of the can with a piece of wood shaped like an oar or paddle. When the paint is reduced to the consistency of thick cream the colour is added if the paint is to be tinted. This colour is mixed separately with a palette knife on a slab or piece of plate glass, and is added in small quantities to the white in the can. The final operation, and a very necessary one, is to strain the paint through wire gauze so as to remove all small unmixed particles. In the best work, paint is twice strained. The custom of using small mechanical paint mixers, worked by hand, is growing among painters. Liquid or ready mixed paints are manufactured in considerable quantities, and are usually sent out in lever-top tins ready for use. These are mixed mechanically in specially constructed paint mixers, having revolving arms or paddles. In the best forms these arms revolve vertically, so as to stir up the heavier part of the paint, which is apt to settle to the bottom. The art of mixing the very large number of different colours required in modern house painting necessitates considerable experience. The following is a short list of some of the commonest colours and their constituents:—BUFF: French ochre and white lead with a little Venetian red. BRONZE GREEN: Chrome green, yellow, and a little black, or chrome yellow and black alone. BROWN (LIGHT): White, mixed with orange chrome and raw umber. BROWN (DARK): Indian red, lampblack, and yellow ochre. BRICK COLOUR: French ochre, Venetian red, and ochre. CARNATION: Carmine lake added to white. FLESH COLOUR: A little yellow ochre and Venetian red added to white. PURPLE: Indian red, ultramarine, and white. SALMON: White lead, vermilion, and a little yellow ochre. TERRACOTTA: White lead and burnt sienna. LAVENDER: Ultramarine and carmine added to white. SKY BLUE: Prussian blue or cobalt added in small quantities to white. CREAM: French ochre

added to white with a little Venetian red. STONE COLOUR: French ochre added to white with a little burnt umber. IVY GREEN: French ochre, lampblack, and Prussian blue. OLIVE: Lemon chrome yellow with a small proportion of ultramarine and Indian red. PEA GREEN: Chrome green added to white. CHESTNUT: Chrome yellow and Venetian red. CHOCOLATE: Burnt sienna and a little crimson *or* Indian red, lampblack, and yellow ochre. FRENCH GREY: Add drop black to white and a very little crimson and blue. CLARET: Red, umber, and a little black.—A. S. J.

Paint Oils (*Dec.*) That group of drying oils which are sufficiently abundant and cheap to permit of their extensive use in house painting. Linseed oil is the principal oil of this class; but walnut oil (*q.v.*), poppy-seed oil (*q.v.*), and Tung oil (Chinese wood oil) (*q.v.*) are also employed to a limited extent. Rosin oil (*q.v.*) is sometimes used in cheap paints, but it is objectionable from the fact that it does not become permanently hard. (*See also* OILS.)

Paint Stripping (*Dec.*) A term used to indicate the removal of a coat of paint from the surface to which it has been applied. This is always necessary when the old paint is very cracked or blistered, and rubbing smooth with pumicestone or sandpaper would be impossible. The most common method of stripping paint is to employ a painter's torch or naphtha lamp, which is held in the left hand so that the flame is directed over about a square foot of the old paint at the time, the heat causing the paint to quickly soften. This is then removed by means of a specially constructed knife having a square and sharpened end, and held in the right hand. A portable charcoal stove fitted with a long wooden handle is sometimes employed for the same purpose, or a jet of gas taken from an ordinary gas burner by means of a rubber tube may be employed instead. All these methods have the objection that when used indoors they cause a good deal of smoke and smell. Various solvents are, therefore, sometimes employed instead. They consist of two classes, the first being a paste consisting principally of an alkali which softens the paint after having been applied about a quarter of an hour, so that it may then be washed off; the second class consists of various liquids, of which acetone is one of the principal constituents: this is cleaner than the paste, but can hardly be used with advantage outdoors when a high wind is blowing, as the liquid evaporates before the paint is properly softened.

Pair *or* **Pare** (*Mining*). A Cornish term for a gang of miners (more than two in number).

Palæontology (*Geol.*) The branch of science which is concerned with the study of the Past Life of the Earth. Its pursuit requires an extensive knowledge of biology as well as geology, and its followers are now becoming, in consequence, more and more specialists in its various branches.

Palæozoic (*Geol.*) A term much in use even yet for the strata which contain the oldest types of organic remains yet known, from the base of the Cambrian Rocks upward to the top of the Carboniferous Rocks. By some it is still considered to include also the so-called "Permian" Rocks, which, however, in reality forms the natural base of the Mesozoic Rocks. The Palæozoic Rocks are now usually sub-divided into an Upper or Deuterozoic Series, and a Lower or Protozoic (*q.v.*)

Palaestra (*Archæol.*) A public building used by the Greeks as a gymnasium. The chief athletic exercise taught was wrestling.

Pale (*Her.*) One of the honourable ordinaries: a band placed vertically in the middle of the shield, reaching from top to bottom, and occupying about one-third of the field. *See under* HERALDRY.

Palette (*Arm.*) A small plate of metal of various shapes attached to plate armour to protect the armpit

—— (*Eng.*) The breastplate or part of a hand-drill to which the pressure is applied.

—— (*Paint.*) An implement used by painters for the purpose of setting and mixing colours when painting. It generally consists of a flat thin piece of wood (walnut or pear) or porcelain, oval or rectangular in shape, with a hole at one end suitable for the thumb of the left hand to pass through when in use.

Palette Knife (*Paint, etc.*) A thin, flexible blade of metal or other material fixed in a handle. Used for mixing colours on a palette or for laying the paint on certain parts of the canvas; also for spreading printing ink over a surface.

Palimpsest (*Archæol.*) An ancient parchment or other writing material from which the original writing has been effaced to make place for a subsequent writing. The term is sometimes applied to a monumental brass (*q.v.*) which has been turned and engraved on the reverse side.

Paling (*Carp. and Join.*) A fence formed of thin boards overlapping each other longitudinally, and nailed to the rails.

Palisading (*Carp. and Join.*) A fence with battens a few inches apart nailed to the rails.

Pall (*Her.*) A charge in the form of the letter Y. Derived from a vestment peculiar to archbishops, which consisted of a circular band of lambswool worn round the neck, with two pendants of the same width, one before and one behind. Only the front portion is shown in the charge, and this bears crosses *paté fitchée*.

Palla (*Archæol., etc.*) A loose garment or robe worn by Roman women over their other garments. A plain or ornamented cloth used to cover the chalice.

Palladian. A style of architecture named after its introducer, Andrea Palladio (born 1518, died 1580). "It is a sort of medium between that vigorous severity which some exclusive minds abuse in the endeavour to imitate the classic style, and the licentious anarchy of those who refuse to recognise rules, which rules allow of exceptions" (Gwilt's *Encyclopædia of Architecture*, 1891, p. 1331). Palladio's principal works are: S. Giorgio Maggiore, Venice, Basilica, Vicenza (his masterpiece). In England, Inigo Jones (1572—1652) introduced the Palladian style. The banqueting-hall in Whitechapel is an example of his work.

Palladium (*Chem.*) Pd. Atomic weight, 106·5. A shining white metal; melts about 1500°; sp. gr. 11·4; malleable, ductile. The metal easily absorbs hydrogen (*see* OCCLUSION), and this occurs best on warming. Use is made of this property in gas analysis when hydrogen has to be estimated other-

wise than by explosion with oxygen. The metal is partly oxidised in air at a high temperature; it dissolves in nitric acid, forming the nitrate Pd $(NO_3)_2$. Palladium forms a series of salts in which it is divalent; the most characteristic of these salts are: (1) The cyanide, which is formed as a pale yellow precipitate, when mercuric cyanide is added to a solution of a palladium salt; the cyanide gives the metal on heating, and dissolves in potassium cyanide to form a double salt. (2) The iodide PdI_2, which is formed as a black precipitate on adding a solution of potassium iodide to one of a palladium salt; it is insoluble in hydrochloric acid. This metal also forms double chlorides with potassium and ammonium chlorides, *e.g.* K_2PdCl_4 and K_2PdCl_6, the former being the more stable. Palladium occurs free, sometimes nearly pure, but usually with platinum, osmium, etc. It can be separated from the aqua regia solution by nearly neutralising it and precipitating as cyanide. Finely divided palladium can be obtained by boiling a solution of one of its salts with alcohol and caustic soda.

Palladium (*Min.*) This rare element occurs in two forms. The mineral known as PALLADIUM consists of an alloy of the element palladium with platinum and iridium, and is cubic in its crystalline system. The mineral ALLOPALLADIUM is rhombohedral, and consists of pure palladium. Both are found in association with iridium and platinum in Brazil and in the Urals.

Pallas (*Astron.*) The second of the minor planets discovered. Found by Olbers in 1802.

Pallet (*Bind.*) A narrow tool of brass fixed in a handle, and having a straight or a slightly convex working surface. Used for finishing the backs of bound or half-bound books with plain or ornamental lines, either in gilt or antique style.

—— (*Her.*) A diminutive of the pale and one half its width. *See under* HERALDRY.

Pallets (*Clocks and Watches*). The "pads" by which the escape wheel teeth transmit energy to the pendulum or balance.

Pallium (*Archæol., etc.*) The Latin name for the outer garment or cloak worn by the Greeks, especially by the philosophers. *See* HIMATION. A woollen vestment or scarf worn by archbishops in the Roman Catholic Church. *See* PALL (*Her.*)

Palmæ (*Botany*). A highly important order of Monocotyledons found in tropical and sub-tropical regions. The most common form consists of a single stem with the leaves arranged in a crown at the top. *Cocos nucifera* is the Cocoanut Palm. *Sagus Rumphii* (found in the Moluccas) contains starchy material in the stem, from which Sago is obtained. Many other genera are economically important, while some are cultivated on account of their ornamental appearance.

Palm Capital (*Architect.*) A form of capital used in Egyptian architecture. It resembles a series of spreading palm leaves. *See* CAMPANIFORM CAPITAL, CLUSTERED LOTUS BUD CAPITAL, *and* HATHOR HEADED CAPITAL.

Palmer Tyre (*Cycles, Motors*). *See* TYRES.

Palmitic Acid (*Chem.*) $CH_3(CH_2)_{14}COOH$. White crystalline solid; melts at 62°; boils at 278·5° under 100 mm. pressure; insoluble in water; soluble in alcohol and ether. Occurs free in palm oil; but usually it is combined with alcohols forming esters. Thus its cetyl ester is chief constituent of spermaceti. *See* CETYL ALCOHOL. Its myricyl ester, $C_{15}H_{31}COOC_{30}H_{61}$, forms about 80 per cent. of beeswax; its glyceryl ester is the chief constituent of palm oil, and occurs in olive oil, butter, cocoanut oil, soft animal fat. Adipocire, a waxlike substance found when the bodies of animals decay in the earth, is principally potassium and calcium palmitates. Palmitic acid can be prepared from palm oil by hydrolysing with caustic potash, decomposing the solution of potassium oleate and palmitate with sulphuric acid, and crystallising from alcohol till pure. Oleic acid is much more soluble in alcohol than palmitic acid.

Palm Oil. An oil, fat, or butter obtained from the fruit of several species of the palm, chiefly *Elæis guienensis*. When fresh it is of a bright orange colour, and possesses a pleasant odour like violets or orrisroot; but on exposure it soon becomes rancid, and has then a very unpleasant smell. It is used in this country principally for soap and candle making. The sp. gr. at 15° C. is 0·945, and the melting point 27° to 45° C., according to the quality and condition of the oil.

Palm Wax (*Botany*). A species of palm, *Ceroxylon andicolum* (order, *Palmæ*), from South America; yields a waxy secretion used in candle making.

Palstave (*Arms*). A celt of bronze or other metal without a socket, but made so that it could be attached to a handle and used as a weapon.

Paludament (*Archæol.*) A cloak worn over their armour by the highest Roman military officers. A herald's coat.

Paly (*Her.*) A shield is called "paly" when divided by an equal number of vertical lines, the spaces being alternately of metal and colour. *See* HERALDRY.

Paly Bendy (*Her.*) When the last shield is divided by an equal number of lines drawn bendwise.

Pamphlet (*Print.*) A small book containing from one to five sheets stitched together, and generally put into a paper wrapper. A short essay or treatise published alone.

Panama Straw. The fan shaped leaves of a tropical South American plant, *Carludovica palmata* (order, *Cyclanthaceæ*), when very young, are cut into strips and bleached. This material is used for making so-called Panama hats, which are manufactured chiefly in Ecuador and Peru.

Panathenæa. The great annual festival of Athens which celebrated the union of Attica under Theseus. The festival every fifth year was more elaborate than those during intervening years. The celebration included a grand procession to the shrine of Athena (*see* ELGIN MARBLES), musical competitions, and athletic competitions.

Pan Closet (*Hygiene*). The pan or container closet consists of a china basin shaped like an inverted cone, with its outlet guarded by a movable metal pan, which retains water in the basin. This metal pan not only rapidly fouls and wears out, but each time the basin is emptied allows foul air to escape. It is the most objectionable form of closet, and is now prohibited by the model byelaws of the Local Government Board.

Pandemic (*Hygiene*). The term applied to a disease prevalent over a large portion of the globe.

Pane. (1) One of the sheets or pieces of glass forming the divisions of a window, etc. (2) One of the sides of the table or upper portion of a brilliant or cut diamond. (3) The dressed surface of a stone. (4) In irrigation, a space of ground bounded by a feeder and an outlet.

—— (*Eng.*, *etc.*) The narrow end of a hammer head. *Also spelled* PENE, PEEN, PIN, *etc. See* HAMMERS.

Panel. (1) A portion of a surface surrounded by a frame or border and often consisting of some thinner material, *e.g.* the panel of a door. (2) A thin board employed instead of cardboard or canvas in water-colour and oil painting. (3) A large photograph of much greater height than width.

—— (*Bind.*) One of the spaces between the bands on the back of a bound volume. A division or compartment on the cover of a book enclosed by lines or contained within a border.

—— (*Carp. and Join.*) A thin board occupying the spaces between the styles, rails, and muntings of framed joinery.

—— (*Eng.*) The spaces between the upright pieces of a built up girder or similar structure.

Panel Board (*Elect. Eng.*) A SWITCH BOARD (*q.v.*) built up in panels instead of being in one piece.

Panel Gauge (*Join.*) A long marking gauge; the rod or stem may be from 1 ft. to 2 ft. long. It derives its name from the fact that it is used in gauging the width of panels and similar pieces of work.

Panel Machine (*Join.*) A wood planing machine used for planing up small pieces of flat board, such as panels.

Panel Picture (*Paint.*) A picture painted on a panel of wood. The earlier artists frequently painted on panels.

Panel Saw. A joiner's saw for cutting wood across the fibres. It resembles a hand saw, but is smaller, and has about seven to nine teeth to the inch. *See* SAW.

Panes (*Cost.*) Slashes in outer garments, *e.g.* doublets, to show the coloured lining, or to allow of an under garment being seen. This style was much in evidence during the fifteenth, sixteenth, and seventeenth centuries.

Pan Head (*Eng.*, *etc.*) A flat headed rivet.

Panicum (*Botany*). A genus of grasses belonging to tropical and warm temperate regions. Indian millet (*P. miliaceum*) is a valuable cereal.

Pannier (*Architect.*) A CORBEL (*q.v.*)

Panning. The operation of washing auriferous sand, etc., by placing it in a pan to which a slight motion is communicated by the hand. This causes the particles of gold to accumulate at the bottom, the sand, etc., being allowed to pass over the edge with the water.

Panorama. A picture of a landscape or other scene in which all objects that are visible from a fixed point are represented on the inner side of a cylindrical surface, the point of view being the axis of the cylinder; or the picture is unrolled before the spectator, showing the various parts in succession. Invented by R. Barker, of Edinburgh, about 1788.

Pantagraph. *See* PANTOGRAPH.

Pantheon (*Architect.*) A circular building with a domical roof, built by Hadrian in Rome (A.D. 117–138) The portico of sixteen Corinthian columns was taken from an older building erected on the same site by Agrippa in the reign of Augustus. The following are some of the principal dimensions of the Pantheon: Internal diameter, 142 ft. 6 in.; external diameter, 188 ft.; height from floor to outside of "eye," 148 ft. 4 in.; thickness of dome at eye, about 6 ft. The building is lighted solely by means of a circular opening or "eye" in the centre of the dome. This eye is 27 ft. in diameter, and each square foot of it lights nearly 3,400 cubic ft. of the interior.

Pan Tile (*Build.*) A double curved roofing tile.

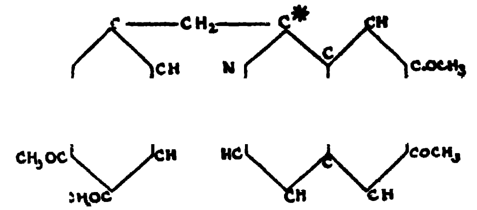
Pantograph. An instrument used for making copies of drawings of a different size from the original. The pencil which draws the copy is connected with a tracing point by a set of jointed link work, so that the movement of the pencil always bears a constant ratio to the movement of the tracing point.

—— (*Lace Manufac.*) An enlarged form of the ordinary pantograph mechanically adapted for producing designs upon fabric in the Swiss embroidery machine.

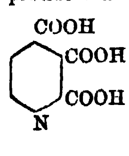
Papain (*Botany*). *See* PAPAW.

Papaver (*Botany*). The poppy is a member of the *Papaveraceæ*. *P. somniferum* yields the drug OPIUM.

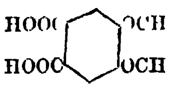
Papaverine (*Chem.*)



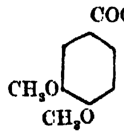
A white crystalline (prisms) alkaloid; melts at 147°; insoluble in water; soluble in chloroform; sparingly soluble in cold, easily soluble in hot, alcohol; in benzene and amyl alcohol soluble to the extent of one part in 37 and 76 parts respectively; optically inactive. It is a tertiary base, as it unites with ethyl iodide; hydriodic acid removes four methyl groups. On reduction with tin and hydrochloric acid, it adds four hydrogen atoms to the ring marked 1, and the carbon atom marked with an asterisk becomes asymmetric; the new base—tetrahydropapaverine—can be resolved into the dextro- and lævo-forms by δ-bromcamphorsulphonic acid. On cautious oxidation with potassium permanganate and sulphuric acid, the CH_2 group of papaverine becomes a CO group, and the papaveraldin so formed behaves like a ketone; also it dissolves in concentrated sulphuric acid, giving a deep coloured solution (Oxonium compound). On stronger oxidation of papaverine, the products are:



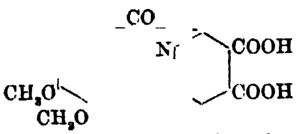
α β γ pyridine tricarboxylic acid—from ring 1.



Metahemipinic acid—from ring 2.



Veratric acid—from ring 3.



Papaverinic acid—from rings 1 and 3.

That papaverine is an isoquinoline derivative is shown by the fact that papaveraldine (*see* above) yields dimethoxyisoquinoline on potash fusion. All these reactions are in accordance with the above formula. Papaverine occurs to the extent of about 1 per cent. in opium. It can be obtained from the mother liquor remaining after the separation of morphine and codeine hydrochlorides (*see* MORPHINE) by precipitation, as dioxalate on addition of oxalic acid; the oxalate is decomposed by calcium chloride, and from the resulting solution of its chloride the papaverine can be precipitated by ammonia, and crystallised from a mixture of alcohol and ether.

Papaw (*Botany*). The edible fruit and leaves of *Carica papaya* (order, *Caricaceæ*) are valued as the source of PAPAIN, a nitrogenous ferment having the power of digesting the fibres of meat. The tree is indigenous to South America, but is now cultivated in many tropical countries.

Paper. On account of modern developments in the process of manufacture, namely, the employment of fibres other than those of cotton and linen, the old definition of paper as a "substance made from rags" must be modified to read "a substance composed of vegetable fibres suitably united or felted together into the form of a sheet." The present method of making paper from rags may be described briefly as follows. The rags, mostly imported from abroad in huge bales, are disinfected by exposure to high pressure steam or to the action of chemical vapours in closed vessels. They are then carefully assorted according to quality and colour; all extraneous matter, such as string, pieces of wood, metal, etc., being removed during the operation. The next process—*viz.* CUTTING—is performed either by hand or by machinery, the better qualities of paper being made from hand-cut rags, which are reduced to pieces about 4 in. square by bringing them into contact with a large knife fixed to a bench. In this form they are passed through a special machine, which knocks out the dust and dirt, and automatically delivers them to the boiler house. Here they are boiled, under pressure, with caustic soda or with lime, in order to remove grease and the non-fibrous constituents of the rags. The better qualities are treated for eight or ten hours with about 10 per cent. of their weight of caustic soda. The removal of the dirty liquid produced is effected by a thorough wash in the rag engine, a machine so constructed that the rags are circulated continuously between the knives of a revolving cylinder and other sharp knives fixed to the bottom of the engine. The rags are thus torn up into separate fibres, while at the same time the dirty water is removed by a contrivance known as a drum washer. The addition of bleach liquor to the pulp in the breaker or rag engine whitens the "half stuff," as the pulp in this condition is called; but in many cases the bleaching is effected in a separate machine known as a potcher, similar in construction to the rag engine. After the complete removal of the bleach liquor residues by thorough washing, the half stuff is more completely torn up or beaten by continuous circulation between a fixed bed plate of knives bolted to the bottom of the beating engine and a rotating beater roll also provided with knives. HAND MADE PAPER: The beaten pulp is now mixed with water in a large deep wooden tank or vat. A mould (a wire cloth fastened to a wooden frame), fitted with a deckle or movable frame forming a raised edge to the wire cloth, is dipped into the vat, and a quantity of diluted pulp lifted out. By a gentle lateral motion imparted to the mould the fibres are caused to interlace or felt together while the water drains through the wire, leaving a wet sheet of paper on the wire cloth. The deckle is removed, and the mould laid upside down on a piece of felt or woollen cloth. A slight pressure applied to the mould causes the wet sheet to adhere to the felt, so that the mould can be removed. A second felt is placed over the wet sheet, and the next sheet formed laid upon it. In this way a pile or post, as it is called, of about 144 sheets is obtained, and this is submitted to great pressure, to take out the excess water. The sheets are hung up to dry, and subsequently sized by immersion in a solution of gelatine, and then again dried. The paper when dry is glazed by pressure between polished plates or by friction between polished rolls, which impart a finished surface to the paper. MACHINE MADE PAPER: In 1799 Louis Robert, a Frenchman, devised a means for making a long sheet of paper on an endless wire cloth. The idea was improved by Fourdrinier, and in 1804 the machine became a practical success. Since this date numerous additions and improvements have been made, so that it is now possible to make the cheaper qualities of paper 144 in. wide at a speed of over 400 ft. a minute. The pulp, after treatment in the beating engine, is discharged into stiff chests (corresponding to the vats used in making paper by hand), and then pumped, mixed with a due proportion of water, along sand traps, which serve to take out mechanical impurities and dirt. It is then screened through brass plates provided with fine slits or cuts, and allowed to flow over a flexible rubber cloth or apron on to the endless wire. By means of a continuous shaking motion the wet pulp felts into a web or sheet of paper, the excess of water falling through the wire. Further moisture is removed by suction or vacuum boxes and by the couch roll, the latter also causing the fibres to felt together more completely. The wet web then passes through press rolls to ensure perfect felting and even thickness, and the paper is dried by passing over hollow cylinders heated internally by steam. It is then formed into large reels. The paper, now in the form of a reel, is passed through a trough containing animal size or gelatine, and led over a large number of skeleton drums, and slowly dried by warm air. A glazed or shiny surface is imparted to the paper, by means of polished rollers, on another machine called a calender. OTHER RAW FIBRES: The removal of excise duty from paper in 1869 soon created a larger demand for paper, and eventually raw materials other than rags had to be found. Those principally used are: (1) STRAW and ESPARTO, each containing about 45 to 50 per cent. of fibrous material suitable for paper-

making. The remainder, consisting of resinous and siliceous matter, is dissolved out in the preparatory treatment. Straw is used largely for cheap papers and box boards. Esparto is used chiefly in book and magazine papers. (2) JUTE AND MANILLA, used for the manufacture of wrappers and strong envelope papers. (3) WOOD PULP, used for all varieties of paper. For details of manufacture *see* WOOD PULP. The pulp, prepared by the chemical process, is suitable for high class papers. A pulp prepared from wood by a mechanical process is only employed for the manufacture of cheap printings and news. The preparatory treatment of the wood involves processes of boiling, breaking, and bleaching similar to those used for rags, although differing in degree. METHODS OF TREATING THE CHEAPER RAW MATERIALS: By blending two or more pulps a great variety of cheaper papers is obtained. Writing papers can be made from rags and chemical wood pulp; magazine and book papers from esparto and chemical wood, cheap printings and news from chemical and mechanical wood. The pulps, suitably blended and beaten, are in the cheaper grades of paper, sized by adding resin size to the pulp in the engine, and not by the use of expensive gelatine. The resin size is made by boiling resin in carbonate of soda. The size is added to the pulp, and then the further addition of alum precipitates the resin on the fibres and renders the pulp partially waterproof. Certain mineral substances, such as China clay, terra alba, etc., are added to the pulp to give weight and to improve the appearance of the paper. The final glazing or surfacing of papers of this class is not always effected on a separate machine. The paper machine is provided with suitable calenders or polished rolls, and the paper glazed as it leaves the drying cylinders. In other respects the manufacture of the cheaper qualities resembles the manufacture of the better machine made grades. VARIETIES OF PAPER: A complete list would fill one or two columns. COLOURED PAPERS are obtained by adding aniline dyes to the pulp in the beater. WATERPROOF PAPER, such as the Willesden paper, is prepared by passing ordinary paper through a bath of cupro ammonium, which acts on the surface of the paper, partially dissolving it. This on drying forms a glazed coating impervious to water. IMITATION PARCHMENT is ordinary paper passed through a bath of sulphuric acid, which has the peculiar effect of toughening the fibres. The acid is washed out and the paper dried in the usual way. TRACING PAPER is ordinary unsized paper coated on one side with a varnish of Canada balsam and turpentine. OILED PAPER for copying books is prepared by brushing over ordinary paper with boiled linseed oil. ART PAPERS used for lithographic printing are made from wood and esparto, coated, after being made, with a mixture of China clay or barytes and glue. DUPLEX PAPERS are coated on each side with a different coloured mixture. HISTORICAL POINTS: The following table is a summary of the more interesting dates in connection with the industry (the early ones being only approximate):

Palm leaves in use before . . .	B.C.	2000
Bark of trees employed about . .	..	2000
Papyrus used as early as	„	2400
Parchment and skins in use about .	„	200
Rice and bamboo used in China about	A.D.	200
Rags known in China before . .	„	700
Rags brought to Europe by the Moors	„	1000
Cotton paper known in England about	„	1300
First mill in England built by Tate .	„	1498
Spielman's mill at Dartford erected .	„	1588
Whatman's mill erected at Maidstone	A.D.	1760
Paper making machine invented .	„	1799
Excise duty on paper removed . .	„	1860
Straw used for making paper . .	„	1851
Esparto introduced by Routledge .	„	1852
Wood pulp, the staple fibre of cheap paper	„	1866

The improvements since 1866 are of a mechanical nature, chiefly relating to speed, output, economy, and other minor details. MODERN BIBLIOGRAPHY: *Papermaking* (Cross & Bevan), *Practical Papermaking* (Clapperton), *Manufacture of Paper* (Davis), *Chemistry of Paper* (Little).—R. W. S.

Paper Cable (*Elect. Eng.*) A cable in which paper is used as a part of the insulating material.

Paper Condenser (*Elect.*) A condenser formed of sheets of tinfoil separated by sheets of paraffined paper.

Paperhanging (*Dec.*) The art of affixing paper and other wall coverings to the surface of walls, ceilings, etc., for the purpose of decoration. The work of a paperhanger now includes hanging (*i.e.* affixing) with an agglutinant, plain and printed paper; pressed or moulded materials having a design in relief, such as Anaglypta, Cordelova, Lincrusta Walton, Cameoid, etc.; canvas hangings, such as Fabrikona; silk mounted on a paper backing, and other materials. The following are the chief varieties of paperhangings in common use:—"PULPS," sometimes called "BLANKS," which are the commonest description of wallpaper made, and have the pattern printed directly on the plain paper. This may be either white or brown, and provides one of the colours which form the pattern. "MACHINES" are papers printed by machines, and comprise a very large variety. In this class of paperhanging the paper is usually first grounded, that is, coloured with distemper colour applied by revolving brushes. The various colours comprising the pattern are then printed by a series of rollers, which are frequently all contained on a single machine, so that the grounded paper enters the machine at one point, passes over the various rollers, and emerges from the other end completely printed, if necessary in as many as a dozen or more colours. It is then taken up automatically in loops or festoons, and carried slowly along the drying room, heated by steam pipes, so that the pattern is quite dry by the time the paper reaches the farther end. Here the long lengths are cut up into rolls and are ready for shipment. "GOLD" or "METAL" PAPERS are those in which bronze or imitation gold leaf occurs, but their use has now declined. "GROUNDS," sometimes called "TINTS," are plain tinted papers without pattern. They are used for plain friezes, ceilings, and for lining cupboards, etc., and are made in a large variety of light and deep colourings. "MICAS" are papers grounded in a composition of which mica, talc, and other similar substances form part, the object being to give an iridescent surface. "SATINS" is a term applied to glazed papers having a smooth polished surface, produced by polishing with French chalk. These papers are usually printed in delicate patterns, and are largely used for drawing rooms, bedrooms, ladies' boudoirs, etc. FLOCK PAPERS have a raised pattern formed by finely shredded wool dusted on an adhesive material in which the pattern is printed. Sometimes silk shreds are used instead of wool; the paper is then called a "silk flock." "SANITARIES" is a term applied to those papers which are printed in oil colours, in contradistinction to distemper.

The best qualities permit of the surface being washed with soap and water. "INGRAINS" are now largely used. They are made by adding colouring matter to the paper pulp, and when closely examined will be found to consist of small hairlike portions more strongly coloured than the remainder. They are used quite plain in various colours, and form an excellent background for pictures. They are also made printed in various patterns, usually of a simple character. Hand stencil friezes are now largely used with ingrains. The objection to all ingrained papers is that, being coloured by dyes, they do not hold their tints well. They are of an absorbent nature, and require considerable care and skill in hanging. Those having a white backing are the best, as they prevent the paste, when applied, soaking through. A piece of English made paper measures 12 yds. long and is 21 in. wide when trimmed, *i.e.* when the marginal selvedge is removed, thus giving an area of 63 sq. ft. or 7 sq. yds. Hence the number of pieces required for any particular room is quickly calculated by ascertaining the total superficial area of the walls, although the exact quantity depends largely upon the size of the pattern, large patterns cutting to waste. French, German, and American papers are now used to a considerable extent at home, and are sometimes made in English lengths and widths. French papers, if not specially produced for the English market, are 9 yds. long and 18 in. wide, and the United States papers are the same width and 8 yds. in length.

The first operation of a paperhanger is to trim the paper. This is often done by means of shears, the roll of paper being held in the left hand and re-rolled as the edge is taken off with the shears held in the right. Various machines and appliances for trimming paper are more or less used, the most successful being one in which the paper is held on a rod and rapidly re-wound on to another rod by a simple system of bands, the edge being removed by two sharp discs held just in the proper place. By means of one of these machines a piece of paper may be trimmed in a few seconds. Another successful appliance for the purpose is used after the paper is pasted. It consists of a metal straight edge having a groove in which runs a small appliance containing a sharp edged revolving wheel. The paper having been pasted, it is folded toward the centre, the pasted surface inward; it is then placed against the straight edge, and is trimmed through the two thicknesses by a single stroke of the handle. The first process in hanging paper is to remove the old paper, if there be any. This is wetted and scraped off, and the plastered surface of the wall is then repaired, where necessary, by means of plaster of Paris. In the cheaper class of property it is a common practice to paper a room without removing the old paper, so that in course of time there may be as many as a dozen different papers on the wall. This is a very dirty and unsanitary practice, and is forbidden in some cities by the local laws. In hanging paper, the safest plan to follow is to strike a vertical line by means of a plumbob, as, if the door or window frame should not be quite perpendicular, it would lead to considerable trouble later. Sometimes the joints of the paper are lapped, that is, only one of the selvedge edges is removed. This mars the appearance of the wall, and in all the best work both edges are trimmed, giving what is known as a "butt joint." The paste used is made of wheat flour mixed with boiling water into a stiff batter and stirred free from lumps. A small quantity of powdered alum is usually added to stiffen the paste and prevent it turning sour. Borax, copperas, or carbolic acid may be used for the same purpose. Formaldehyde is an excellent preservative of paste, and does not discolour the paper as alum is apt to do. The pasted paper is pressed to the wall by means of a clean cloth, but a much quicker way is to use a paperhanger's brush, which has long flexible hairs, and by means of which the paper may be fixed in position with a single sweep of the arm. In high class work rollers of various forms are used to press down the paper at the joints. The various relief materials are as a rule fixed in position by means of paste, to which a little glue has been added. A good deal of judgment is required as to the length of time these materials should remain soaking after the paste has been applied, as, if too much time be given, there is danger of the relief being lost. The old fashioned whitewashed ceilings are rapidly giving place to papered ceilings, special paperhangings being made for the purpose, mostly in a very light pattern and of geometrical design. In other cases relief ceiling decorations are used with excellent effect, although the objection urged against them is that they masquerade as plaster. The chief objection urged against all decoration done in portable material, such as wallpaper, etc., is that they show at a glance that they are not designed specially for the position they occupy. To remove this difficulty various expedients have been tried during recent years, among them being one invented by Mr. Walter Crane, in which the joints, instead of being vertical, were zigzag or irregular, following the patterns in such a manner that they could hardly be seen at all when the paper was hung. Quite a recent production in England, although known in the United States for many years, is the "Crown" frieze. It consists of a frieze design printed in continuation and forming part of the pattern beneath. In this case there are usually three lengths to each roll of paper, and these lengths are sufficiently long to be suitable for even a very high room, the lower portions of course being cut to waste in the case of lower apartments. Another expedient of the same character was brought out in the year 1904 for the first time, and consists of a frieze printed in such a way that the lower portion is intended to be cut away close to the pattern, so that the horizontal line seen in most friezes is absent.—A. S. J.

Paper Joint (*Pattern Making*). A pattern is often built up of a number of small pieces, arranged for convenience of working on a flat surface. To facilitate the removal of the finished pattern, a sheet of paper is first glued to this surface, and the various segments or parts of the pattern are glued on to the paper. When complete, the whole pattern is readily detached from the surface by splitting the sheet of paper.

Paper Mulberry (*Botany*). A Japanese tree *Broussonetia papyrifera* (order, *Moraceæ*) whose inner bark is used in paper making.

Paper Negatives (*Photo.*) Negatives taken on a thin and fine grained paper, which is coated with a sensitive film; for printing the paper is rendered transparent by treatment with oil or wax. *See also* STRIPPING FILM.

Paper Scale (*Eng.*) Various scales printed on paper are used by draughtsmen; they are cheap and convenient for many purposes, though not durable.

Paper Shales (*Geol.*) Very thinly laminated rock of argillaceous composition, in which the layers remind one of the leaves of a book. The structure is due to the slow and intermittent deposition of very fine mud at the bottom of water rarely or never affected by currents.

Paper Varnish (*Dec.*) The varnish used on paper varies in composition according to the quality of work, a mastic varnish being considered best when its high price is not prohibitive. Bookbinders use a colourless varnish made by dissolving three parts of mastic in twenty parts of absolute alcohol and adding one part of bleached shellac. Ordinary paper varnish is made from Australian sandarach and Venice turpentine in the proportion of five of the former to three of the latter by weight, dissolved in methylated spirits. A cheaper grade is made by substituting Burgundy pitch for the Venice turpentine.

Papier Maché. A material manufactured from paper pulp mixed with other substances, *e.g.* size. The pulp is moulded into various utensils and fancy articles, which are then dried and japanned. *See also* STEREOTYPE.

Pappus (*Botany*). An appendage in the form of a ring of hairs or scales round the top of a fruit.

Papyrus. A substance made from the stem of the papyrus plant, and used by ancient nations, more especially by the Egyptians, as a writing material. The name is applied to an ancient manuscript on papyrus.

—— (*Architect.*) The plant was used in the mud and reed construction of the early Egyptians. In later Egyptian architecture conventional representations of it are very common.

Para-Amido-Phenol (*Photo.*) A concentrated solution of this, containing sodium sulphite and a caustic alkali, is sold under the name of "Rodinal." Images developed with it appear quickly, but gain density slowly.

Parabanic Acid (*Chem.*) $\begin{matrix} OC-NH \\ | \\ OC-NH \end{matrix}\!\!>CO.$

Also called OXALYLUREA. A white crystalline solid; decomposes on heating; soluble in water and in alcohol; behaves like a dibasic acid; its alkaline salts are easily hydrolysed to oxaluric acid, $H_2NCONHCOCOOH$. It is obtained by the action of nitric acid on uric acid or bromine and water on uric acid; and synthetically by the action of phosphorus oxychloride on a mixture of urea and oxalic acid.

Parabola. The plane curve produced if a cone be cut by a plane parallel to the slant side of the cone. It may also be defined as the plane curve described by a point which moves in such a manner that its distance from a fixed point, the FOCUS, is always equal to its distance from a fixed straight line, termed the DIRECTRIX.

Parabolic Girder (*Eng.*) A girder whose profile is formed by an arc of a parabola on one edge and a chord of the parabola on the other. This form is of uniform strength, *i.e.* the maximum stress is the same at every section of the girder.

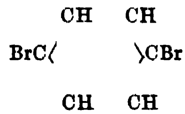
Parabolic Governor (*Eng.*) A governor (*q.v.*) with crossed arms. The path of the balls is approximately a parabola as they fly out from the axis. This form gives a very sensitive governor. *See* GOVERNORS.

Parabolic Mirror (*Light*). A mirror whose principal cross section is an arc of a parabola. Light diverging from a point coinciding with the geometrical focus of the curve forms a pencil of parallel rays after reflection from the surface of the mirror.

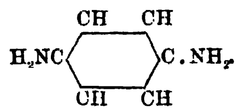
Para Compounds (*Chem.*) The prefix para is used in two ways in chemistry. First, it is used to denote a substance which is a polymer of another substance. Examples: Paracyanogen and para-aldehyde, which are polymers of cyanogen and aldehyde respectively:

C_2N_2 Cyanogen. $(C_2N_2)_n$ Paracyanogen.
C_2H_4O Aldehyde. $(C_2H_4O)_3$ Para-aldehyde.

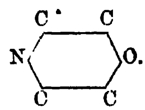
Second, it is used to denote any two diametrically opposite carbon atoms in the benzene ring, and occasionally any two diametrically opposite carbon or other atoms in heterocyclic six membered rings. Examples:



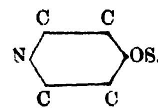
Paradibrombenzene.



Paraphenylenediamine.



Paraoxazine Ring.



Parathiazine Ring.

Paraffins. (*Chem.*) Hydrocarbons of the general formula C_nH_{2n+2}. Examples:

Methane, CH_4	Boils at	$-160°$
Ethane, $CH_3.CH_3$	,, ,,	$-93°$
Propane, $CH_3.CH_2.CH_3$	,, ,,	$-38°$
Butane, $CH_3.CH_2.CH_2CH_3$	,, ,,	$+1°$
Isobutane, $(CH_3)_2CH.CH_3$	,, ,,	$-17°$
Pentane, $CH_3.CH_2.CH_2.CH_2.CH_3$	,, ,,	$+36°$
Isopentane, $(CH_3)_2CHCH_2.CH_3$	,, ,,	$+28°$
Tetramethylmethane, $C(CH_3)_4$	,, ,,	$+10°$

From the 16 carbon atom member upwards they are solids at the ordinary temperature; the highest member yet prepared contains 60 carbon atoms, and melts at 102°. It will be noticed that isomerism begins at the fourth member; the number of isomers rapidly increases with the number of carbon atoms. *See* ISOMERISM. The boiling points of the isomers are always lower than that of the unbranched chain. The isomers are named in several ways: (1) They may be named as derivatives of methane or ethane. (2) They may be named according to the mode of union of the carbon atoms. Where no carbon atom is united to more than two others we have the unbranched chain compound, or normal paraffin, or primary linking. When one or more carbon atoms are linked to three others we have the isoparaffins or secondary linking. When one or more carbon atoms are linked to four others we have the tertiary linking or neoparaffins. (3) They may be named according to the Geneva system. *See* NOMENCLATURE. The paraffins as a class are distinguished by their great stability towards reagents; they burn in air or oxygen, and form substitution products with the halogens, and some of the higher members are

oxidised and nitrated directly by nitric acid. *See* NITRATION. The branched chain members are more readily attacked than the normal members. They are obtained by a variety of reactions, only a few of which can be given: (1) Heating the sodium salt of a fatty acid with soda lime. (2) The alkyl iodides may be reduced by the zinc copper couple. (3) Heating alkyl iodides with sodium, finely divided silver or copper. (4) Electrolysis of the potassium salt of a fatty acid. (5) Heating a fatty acid with hydriodic acid and red phosphorus. The paraffins occur naturally in a variety of ways; but the chief source is the natural or rock oil found in various parts of the world—America, Russia (Crimea and Baku), Galicia, and many other places; they also occur in the tar from the distillation of bituminous shale. *See also* METHANE, PENTANE. The lower boiling liquid mixtures are used for burning and for solvent purposes. *See* FLASHING POINT. The semi-solids are called Vaselines—used as lubricants and salves. The solids are called Paraffin Wax, and are used in candlemaking. *See also* PETROLEUM.

Paragon (*Typog.*) Type of a size between great primer and double pica. *See* TYPE.

Paraguay Tea (*Botany*). *See* ILEX.

Paraldehyde (*Chem.*) *See* ACETALDEHYDE.

Paraleucaniline (*Chem.*) The leuco-compound (*q.v.*) of PARAROSANILINE (*q.v.*)

Parallax. The apparent alteration of position of an object, relative to other objects, when viewed from different points.

—— (*Astron.*) The angle between two lines drawn from a heavenly body to two places from which it can be observed. Parallax is greatest for bodies nearest to the earth, least for the more distant ones, such as the fixed stars.

—— (*Phys.*) An apparent displacement of an object due to its being viewed obliquely; *e.g.* the needle of a galvanometer, etc., will appear to be displaced relatively to the marks on the scale fixed behind it if the observer's eye be not immediately in front of (or over) the needle.

——, **Annual** (*Astron.*) The angular displacement of a fixed star when viewed from different parts of the earth's orbit (*i.e.* at different times of the year). A fixed star is so distant that its direction appears the same when viewed from any part of the earth, *i.e.* it has no Geocentric Parallax; but a small displacement can be observed from opposite sides of the earth's orbit; then taking the diameter of the orbit as a base line and accurately measuring the angles which the apparent directions of a star make with this line at its two ends, the distance of a star can be calculated. The Annual Parallax of fixed stars is very small, rarely much more than 1 or 2 seconds.

Parallax Error (*Phys., etc.*) An error in reading the indications of an instrument, due to PARALLAX (*q.v.*)

Parallel. Two lines are said to be parallel if they lie in the same plane, but will never meet, however far they may be produced. Curves and surfaces are parallel when they are equidistant from each other at every point.

—— (*Elect.*) Two or more conductors are said to be in PARALLEL, PARALLEL ARC, or in MULTIPLE CIRCUIT when one end of each of them is electrically connected to one conductor by which the current enters them all, the other ends being similarly connected to a conductor by which the current leaves them all. If r_1, r_2, r_3, etc., be the resistance of the separate conductors, then their combined resistance R is given by the equation

$$\frac{1}{R} = \frac{1}{r_1} + \frac{1}{r_2} + \frac{1}{r_3} + \text{etc.}$$

Parallelepiped. A solid bounded by six planes, opposite planes being parallel to each other.

Parallel Gutter (*Build.*) *See* BOX GUTTER.

Parallel Motion (*Eng.*) A form of link work used in beam engines to guide the head of the piston rod in a straight line.

Parallelogram. A four sided plane figure whose opposite sides are parallel.

Parallelogram of Forces, Velocities, etc. If two forces, velocities, or other VECTOR QUANTITIES (*q.v.*) be represented in magnitude and direction by two adjacent sides of a parallelogram, their RESULTANT is represented in magnitude and direction by the diagonal of the parallelogram. Thus if two forces be represented by the sides AB and AD of a parallelogram ABCD, the resultant is represented by the diagonal AC.

Parallel Print (*Foundry*). A CORE PRINT (*q.v.*) made without any TAPER (*q.v.*) This is the case with prints which are to be withdrawn sideways from the mould.

Parallel Ruler *or* **Rule.** A mechanical device used for drawing a number of lines parallel to each other. Its commonest form consists of two flat rulers, joined by two metal links of equal length, so that the four members form the sides of a parallelogram; thus the two rulers always remain parallel to each other.

Parallel Strips (*Carp., etc.*) WINDING STRIPS (*q.v.*)

Parallel Vice (*Eng.*) A vice whose jaws always remain parallel, however far they are opened.

Paramagnetic Substance *or* **Body** (*Elect.*) A substance which when placed in a magnetic field tends to move from the weaker to the stronger part of the field, *e.g.* iron, steel, nickel, and cobalt. Such substances have a PERMEABILITY (*q.v.*) which is greater than unity.

Parameters (*Min.*) The parameters of any crystal plane are numbers which represent the relation of the intercepts of that plane to the intercepts of the unit plane. Thus if the lengths of the intercepts of the unit plane on the axes *abc* were $\frac{1}{2}$, 1, 2, the axial relation of the crystal would be expressed $a : b : c = \cdot 5 : 1 : 2$; and if the actual lengths of some other crystal plane were 1, 1, 1, then the parameters of the second plane would be $\frac{1}{2}$, $\frac{1}{1}$, $\frac{1}{2}$, or 2, 1, $\frac{1}{2}$, or 4, 2, 1, being expressed in the proportional whole numbers. *See* INTERCEPTS.

Paranitraniline Red. *See* DYES AND DYEING.

Parapet (*Architect.*) A low wall constructed for the purpose of protection at the lower part of a roof, or at the sides of bridges, etc. *See* BATTLEMENT.

Parapet Gutter (*Build.*) A gutter constructed behind a parapet wall.

Pararosaniline (*Chem.*)

$$HC\left\langle\begin{matrix}C_6H_4NH_2\\C_6H_4NH_2\\C_6H_4NH_2\end{matrix}\right. \qquad HO.C\left\langle\begin{matrix}C_6H_4NH_2\\C_6H_4NH_2\\C_6H_4NH_2\end{matrix}\right.$$

Paraleucaniline. Leuco-compound of Pararosaniline. Paratriamidotriphenyl Methane.

Colour Base of Pararosaniline. Paratriamidotriphenyl Carbinol.

$$C\left\langle\begin{matrix}C_6H_4NH_2\\C_6H_4NH_2\\C_6H_4:NH_2Cl\end{matrix}\right.$$

Pararosaniline Hydrochloride, commonly called Pararosaniline.

Pararosaniline itself would be $C\left\langle\begin{matrix}C_6H_4NH_2\\C_6H_4NH_2\\C_6H_4:NH\end{matrix}\right.$, and is unknown. Its hydrochloride is a dark coloured crystalline solid with lustrous green reflex; sparingly soluble in cold water, more soluble in hot water; soluble in alcohol. Its solutions are red; it is a red dye; with excess of strong acids it forms yellow solutions. It is obtained by the action of hydrochloric acid on the colour base. The latter is obtained in several ways: one of the most important is as follows: A mixture of aniline, paratoluidine, nitrobenzene, iron filings, and hydrochloric acid is heated to about 180°; the iron and acid form ferrous chloride, which is oxidised to ferric chloride by the nitrobenzene; the toluidine is probably oxidised by the ferric chloride to paramidobenzaldehyde, which condenses with two molecules of aniline to form paraleucaniline, which is further oxidised to the colour base of pararosaniline, and the latter forms with hydrochloric acid the dye pararosaniline hydrochloride. The colour base can be synthesised from triphenylmethane by direct nitration with nitric acid, reduction of the trinitro-compound with acetic acid and zinc, and precipitation with ammonia, when the leuco-compound is formed; this on oxidation easily yields the colour base. When the colour base is diazotised with sodium nitrate and sulphuric acid it yields a tridiazo sulphate, which on treatment with alcohol gives triphenylcarbinol, $OH.C\left\langle\begin{matrix}C_6H_5\\C_6H_5\\C_6H_5\end{matrix}\right.$. On boiling with hydrochloric acid it yields paradiamidobenzophenone, $CO\left\langle\begin{matrix}C_6H_5NH_2\\C_6H_5NH_2\end{matrix}\right.$. On heating with concentrated hydriodic acid at 180°—200°, it yields aniline and paratoluidine. A number of important dyes are derived from pararosaniline by introducing alkyl and other groups in place of some or all of the hydrogen atoms of the amido groups. Examples: *Methyl violet* is the hydrochloride of a mixture of penta and hexamethyl pararosaniline. *Crystal violet* is the hydrochloride of hexamethylpararosaniline. *Methyl green* is methyl hexamethylpararosaniline chloride; its salts decompose at about 120°, losing methyl chloride and forming crystal violet.

Para Rubber. *See* CAOUTCHOUC *and* RUBBER.

Paraselenæ (*Meteorol.*) *See* HALOS.

Parasite. An organism which derives its nutriment from other living organisms. Many plants are more or less parasitic in habit, *e.g.* the Dodder and Mistletoe. *Cf.* COMMENSAL.

Parasites (*Foods*). The chief parasites of animals whose flesh is used for food are the: (1) *Tænia solium*, causing the disease known as "measly pork." (2) *Tænia mediocanellata*, which occurs in the flesh of cattle. (3) *Tænia echinococcus*, which infects cattle, swine, and man, through the medium of water or raw vegetables. (4) *Cysticercus cellulosæ*, the cystic form of *Tænia solium*. (5) *Cysticercus bovis*, the cystic form of *Tænia mediocanellata*. (6) *Cysticercus tennicollis*, chiefly infecting sheep. (9) *Cysticercus fisiformis*, found principally in the peritoneal cavities of hares and rabbits. (10) *Distoma hepaticum*, the liver fluke of sheep. (11) *Trichina spiralis*, producing the disease known as trichinosis (12) *Psorospermiæ oviformis*, found in the livers of rabbits, and more rarely in the intestines of cattle and sheep, causing the diseases known as coccidiosis or psorospermosis. (13) *Cœnurus cerebralis*, found in the brains of sheep. (14) *Strongyli rufescens*, found in the lungs of sheep.

Parastata (*Architect.*) A pilaster or anta.

Parchment. The skin of a sheep, goat, or young calf, specially prepared and used for writing, printing, painting, and taking proofs of engravings, etc.

—— **Artificial.** Another name for PARCHMENT PAPER. *See* CELLULOSE.

Parchmentising. The conversion of cellulose fibre (cotton wool, paper, etc.) into a substance termed ARTIFICIAL PARCHMENT. *See* CELLULOSE.

Parchment Paper. *See* CELLULOSE *and* PAPER MANUFACTURE.

Parclose *or* **Perclose** (*Architect.*) (1) A closet. (2) A screen or railing separating a chapel or tomb from the body of a church. (3) A gallery front.

Pardoe Machine (*Print.*) A rotary printing machine invented by Pardoe & Davis.

Pargasite (*Min.*) A variety of HORNBLENDE (*q.v.*) of a greenish colour from Pargas in Finland. *Also called* NOBLE HORNBLENDE.

Parge, Parget (*Build.*) (1) Plaster made of lime and cow dung, used for lining the flues of chimneys. (2) Plaster spread upon a wall or ceiling. (3) A plastered surface with ornamental designs in relief or indented. This last is also known as Pargeting.

Parhelia (*Meteorol.*) *See* HALOS.

Parian Cement. Is composed of a plaster base, the gypsum being mixed with powdered borax. The mixture is calcined and subsequently ground. *See also* CEMENTS.

Parian Marble. *See* MARBLE (STATUARY).

Paring (*Leather*). The paring down of leather to make it thin and suitable for bookbinding, etc.

—— *or* **Scribing Gouge** (*Carp., etc.*) A gouge having the bevel on the inner or concave side of the blade.

Paring Chisel (*Carp. and Join.*) A long and thin bevelled edge chisel. It is used by the pressure of the hand alone, and never struck with a mallet.

Paring Machine (*Chem. Eng.*) A special cutter for trimming the edges of the oil cakes (which are naturally still oily) after the cakes leave the hydraulic press. The parings are re-ground and put into the "kettle" to be treated with fresh seed. *See* OILS.

Paris Green (*Dec.*) A name used in the United States for emerald green (*q.v.*) It is now principally used as an insecticide, particularly for destroying the "potato bug" or Colorado beetle. *See* EMERALD GREEN.

Parkes' Process (*Chem.*) *See* LEAD.

Parlando (*Music.*) In a speaking manner. A somewhat similar direction to *cantando* or *cantabile* (*q.v.*), but more like a recitative.

Parlantes (*Her.*) *See* ARMES PARLANTES.

Parquet Floor (*Carp. and Join.*) A floor composed of thin layers of different woods, usually ½ to 1 in. thick, formed into a pattern. *See also* PATENT PARQUET.

Parsons' Steam Turbine (*Eng.*) *See* STEAM TURBINE.

Part (*Architect.*) *See* MODULE.

—— (*Music*). (1) A voice or instrument, as the tenor part, the violin part. (2) A portion of a composition.

Parthenon (*Architect.*) The name by which the temple of the Goddess Athena Parthenos on the Acropolis at Athens is generally known. It was constructed during the Periclean period (460—400 B.C.) from the designs of Ictinus and Callicrates. The Parthenon is an octastyle peripteral building, having seventeen columns on each flank. The top of the stylobate measures about 101 ft. by 228 ft., and the columns are about 34·2 ft. in height. The cella (*q.v.*) is amphiprostyle, and is divided into two parts: the naos, entered from the east, and containing the statue of the goddess by Phidias; and the opisthodomus, which is separated from the naos and entered from the west. This building is without doubt the finest example of Greek Doric, and is, in fact, generally admitted to be the masterpiece of Greek architecture. *See* ARCHITECTURE, ORDERS OF; GREEK ARCHITECTURE; *and* ELGIN MARBLES.

Partial (*Sound, Music*). The higher tones which are present in a composite tone. *See also* HARMONICS *and* OVERTONES.

Partial Earth (*Elect. Eng.*) A fault in a telegraph line or other conductor consisting of a partial connection with the earth.

Partial Eclipse (*Astron.*) This occurs when the moon does not exactly eclipse the sun, in the case of a solar eclipse; and when the moon does not completely enter the earth's shadow, in the case of a lunar eclipse.

Partially Polarised Light. An admixture of polarised and unpolarised light.

Parting (*Foundry*). (1) The joint between the masses of sand in two boxes in which a mould is made. (2) The formation of this joint. (3) The separation of the different boxes containing a mould, in order to withdraw the pattern.

Parting Bead (*Carp. and Join.*) The bead let into the pulley styles to separate the top and bottom sashes in a cased frame.

Parting Flask (*Met.*) A flask with a small body and long narrow neck, used for dissolving metals in assaying.

Parting Line (*Foundry*). A line (sometimes marked on a pattern) where the surface of the sand in each half of the mould is to come.

Parting Piece (*Carp. and Join.*) The thin slip that prevents the weights rubbing against each other in the boxing of a cased frame.

Parting Ring (*Foundry*). A large ring of iron carrying the upper part of a loam mould. By means of the ring the upper part of the mould can be lifted just as the top part of an ordinary moulding box is lifted.

Parting Sand (*Foundry*). Dry, non-adhesive sand, spread over the surface of the sand where a parting occurs in a mould to prevent the upper and lower parts from adhering.

Parting Tools (*Eng., etc.*) Narrow turning tools used only for cutting through a piece of work (whether wood or metal) in the lathe.

Partizan *or* **Partisan** (*Arms*). A weapon something like a halbert in shape. It consisted of a broad blade fitted on the end of a long staff and having two ornamental projections, one on each side of the blade near the base. Introduced into England in the reign of Edward IV. Subsequently borne by bodyguards as a mark of dignity.

Party *or* **Parted** (*Her.*) A shield divided down the middle is parted per pale. Partition lines parting the shield into ordinaries are thus described: party per fesse, or per bend, or per saltire, etc. *See under* HERALDRY.

Party Line (*Elect. Eng.*) A telephone wire connecting several subscribers or several stations, as distinguished from a line which connects one subscriber only with the exchange. *See also* TELEPHONE.

Party Wall (*Build.*) A wall separating two tenements.

Parvis *or* **Parvise** (*Architect.*) (1) The open space round cathedrals and churches, probably from *paradise* (a garden). (2) A porch or entrance court to a church or other building. (3) A room over a church porch, such as that at S. Wulfram's, Grantham, which contains a chained library.

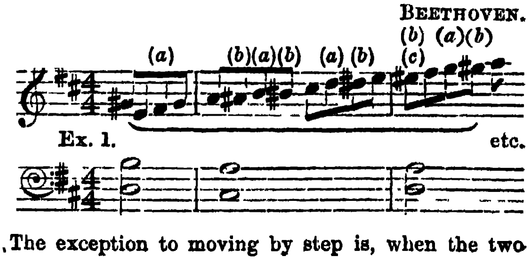
Passed for Press (*Typog.*) A proof with which the author is satisfied is, on being received by the printer, said to be passed for press.

Passiflora (*Botany*). A genus of *Passifloraceæ* (Passion flower family). Several species have edible fruits, such as the Granadilla, Sweet Calabash, and Water Melon.

Passing (*Silk Manufac.*) *See* ENTERING.

Passing Notes (*Music*). Notes foreign to the harmony, but connecting two harmony notes. With the exception given below, they always move by step in the *same* direction from one harmony note to another, and may be either diatonic—Example 1 (*a*)—or chromatic (*b*); but if a chromatic passing note is introduced, the succeeding passing notes should be by step of a semitone till the harmony note is reached. Passing notes may be either on the accented—Example 1 (*c*)—or unaccented parts of the bar (*a, b*).

BEETHOVEN.



The exception to moving by step is, when the two

harmony notes are a third apart the first passing note may leap a third and return to the harmony note, *e.g.*

This is somewhat similar to changing notes, which, however, move round the harmony notes, *e.g.*

Chopin's Pianoforte Étude No. 2 (Op. 10) is full of chromatic passing notes and changing notes.

Passione, Con (*Music*). With passion.

Passive Iron (*Chem.*) *See* IRON.

Passometer (*Surveying*). An instrument recording the *number* of paces taken in walking. The PEDOMETER, which is capable of adjustment to the length of the step, will register the *distance* paced.

Paste (*Chem. Eng.*) A term applied to the solid soap which separates from the leyes after cutting (*q.v.*) It is also applied to all finished soaps which are to be converted into toilet soaps by drying, perfuming, milling (*q.v.*), and plodding (*q.v.*)

—— (*Dec.*) Paperhangers' paste should be made from good wheat flour, the following being the method of mixing: Two pounds of flour are mixed with cold water into a stiff batter; all lumps are beaten out, and the mixture is further thinned with cold water and usually a little alum is added. Borax or formaldehyde are preferable, and alum must not be used if the paste is to be used on papers having delicate colours. Upon the cold batter boiling water is poured, the paste being stirred rapidly until it begins to swell and thicken and to lose some of its whiteness. It is then cooked, but may be further thinned to make it spread easily. It is best not used until cold. When extra strong paste is required a solution of dextrine or British gum should be added. If it is to be used on pressed papers it is usually found advisable to add instead a little glue.

—— (*Elect. Eng.*) The active material (oxide of lead) applied to the surface of the plates or grids in an ACCUMULATOR (*q.v.*)

—— (*Pottery*). *See* HARD PASTE; SOFT PASTE; *and* POTTERY AND PORCELAIN.

Pastel. *See* PAINTING (METHODS).

Paste Points (*Typog.*) A small flat piece of iron, with a pin or spur. It is used for securing register when printing on hand presses. When the appliance is placed in position, the spur protrudes from the tympan and perforates the sheet when the first impression is made.

Pasteur-Chamberland Filter (*Hygiene*). Consists of a metal or glass case containing a tube or "bougie" of unglazed porous porcelain made of kaolin. It is capable of being fixed to an ordinary tap supplying water under pressure—not exceeding two atmospheres—which will force the water through the porcelain cylinders. The resulting filtrate is quite sterile; but it is necessary from time to time to remove the "bougie" and thoroughly cleanse it.

Pasteurisation. *See* MILK.

Paste Wash (*Bind.*) Paste that has been diluted with water; applied to leather bindings to form a suitable surface for the subsequent application of gilt. Glaire (*q.v.*) is applied over the paste wash when the latter is dry.

Pastoral (*Art*). The term applied to pictures after the style of Watteau and Boucher, *i.e.* in which conventional shepherds and shepherdesses figure.

Pastoral Staff (*Her.*) One of the insignia of a bishop and an abbot. They appear on some ecclesiastical shields. *See* CROZIER.

Pasty (*Met.*) Iron is said to be pasty when it is in a viscous condition. This state is made use of in forging, where wrought iron is dealt with; but cast iron which passes through a pasty condition in melting or solidifying is inferior to that which becomes fluid at once.

Pat (*Glass Manufac.*) A flat slab of fireclay, placed on a level with the lower part of the mouth of the pot. Upon this slab the pig rests. *See* POT, ARCH, *and* PIG.

Patchouli (*Botany*). The well known Hindu perfume is obtained by distillation of the leaves of the plant *Pogostemon patchouli* (order, *Labiatæ*). The plant, which is found in Penang, Malacca, and Sylhet, grows to a height of about 2 ft.

Paten. A metal plate or dish, *e.g.* the plate on which the bread is placed in Communion.

Patent Driers (*Dec.*) A paste preparation used for adding to paint to facilitate drying. There are many different formulæ, of which the following is given by Hurst as an example: 15 lb. of dried zinc sulphate, 4 lb. of lead acetate, 7 lb. of litharge ground with 8 lb. of boiled oil. To this mixture is added 100 lb. of Paris white, 50 lb. of white lead, and sufficient boiled oil to make the whole into a stiff paste. Paris white is added in order that the mass shall not harden too rapidly. Much of the patent dryers sold possess very little drying qualities. It is important that these dryers shall not alter the shade of paint with which they are mixed. Manganese salts, *e.g.* the borate, are also used.

Patent Fuel, Briquettes (*Eng., etc.*) Coal dust, etc., mixed with some resinous or gummy substance to act as a binder, and compressed into blocks.

Patent Glazing (*Build.*) There are many kinds of patent glazing, but the principle is the same, *i.e.* there is no putty or other cementing material used, the glass being free to expand or contract. Rendle's "Invincible" and Grover's "Simplex" are well known examples.

Patent Leather. *See* ENAMELLED LEATHER.

Patent Parquet. Wood about $\frac{1}{8}$ or $\frac{1}{4}$ in. thick, of different colours, mounted on canvas by a secret process. At present it is only made in Milan. It has the advantage over ordinary parquetry in being portable, as it rolls up and can be laid like linoleum; while in appearance and wear it is equal to, and undistinguishable from, the old solid laid parquet floor. It forms an ideal hygienic floor covering.

Patent Plate. *See* GLASS MANUFACTURE.

Patera (*Archæol.*) A shallow circular vessel somewhat like a saucer, used by the Greeks and Romans for holding the wine at sacrifices.

—— (*Architect.*) A saucer shaped ornament.

Patetico, Pathetique (*Music*). Pathetic.

Path, Mean Free (*Phys.*) *See* MEAN FREE PATH.

Pathogenic Bacteria. *See* BACTERIA.

Patina. The fine green, semi-transparent crust, consisting of basic copper carbonate, which appears on the surface of copper and bronze when exposed for a length of time to the air. The effect is obtained artificially by immersing copper articles in a bath of acetic acid or other weak acids. The best examples of patina are found on ancient bronzes containing much tin and very little zinc. (2) The mellow tone assumed by the varnish on an oil painting after a lapse of years; the mellow appearance of ancient marble statuary. (3) A shallow bason used by the Romans for domestic purposes. *Cf.* PATEN.

Pattern (*Foundry*). An ordinary pattern is a counterpart in wood of the external form of an object, and is used to form a cavity or mould in sand, which when filled with fluid iron will produce a casting of the required shape. Internal cavities and passages, etc., are not formed on the pattern, but are formed by CORES (*q.v.*) moulded separately and inserted in the mould. A core is held in place by inserting its ends in suitable recesses in the mould. These recesses are produced by projections on the pattern termed Core Prints. Thus a cylindrical hole in a casting will be indicated by two solid projections on the pattern.

Pattern Makers (*Eng.*) The workmen who make the patterns from drawings furnished by the draughtsmen. A pattern maker must possess, in addition to his skill in wood working, an accurate knowledge of the processes of the foundry. The trade is totally distinct from carpentry and joinery.

Pattern Shop (*Eng.*) The part of an engineering works where the patterns are constructed. It resembles an ordinary joiners' shop in appearance and equipment.

Pattinson's Process (*Met.*) *See* LEAD.

Pattinson's White (*Dec.*) A basic chloride of lead obtained by treating chloride of lead with lime. It is white, of good body, but lacks uniformity, and is now almost obsolete.

Paul *or* **Pawl** (*Eng., etc*) A catch or small hinged piece of metal which engages with the teeth of a RATCHET WHEEL (*q.v.*)

Paul Feed (*Eng.*) *See* RATCHET WHEEL.

Pause (*Music*). The sign 𝄐. It denotes that the note or rest over which it is placed is to be prolonged according to the will of the performer (or conductor). If over a bar-line a pause shows that a stop is to be made before proceeding to the following passage, in contradistinction to attacca (*q.v.*) If placed over a double-bar when there has been a "Da Capo," it signifies the end, and corresponds to the word "Fine."

Pavilion (*Architect.*) (1) An isolated edifice such as a small house. (2) A hall of audience in an Eastern palace. (3) A light open structure, such as the building used on a cricket ground for the use of spectators, etc. (4) A strongly marked portion of the front of a building, the roof of which is kept distinct from that of the adjoining work.

Paving (*Civil Eng.*) Covering for a road or footpath which is more durable, less absorbent, and more easily cleansed than a gravelled or macadamised surface. The chief forms are COBBLES, SETTS, FLAGSTONES, WOOD BLOCKS, BRICKS, and various compositions, such as ASPHALT, GRANOLITH, etc.

Paving Tiles (*Build.*) Flat coloured tiles 3 in. to 6 in. square and thicker than roofing tiles.

Paw (*Her.*) The foot only of an animal, generally extended or outstretched.

Pawl. *See* PAUL.

P.D. (*Elect.*) A symbol for POTENTIAL DIFFERENCE (*q.v.*)

Pd. (*Chem.*) The symbol for PALLADIUM (*q.v.*)

Pea (*Botany*). The seeds of this well known food plant, *Pisum sativum* (order, *Leguminosæ*), are highly nutritious, in consequence of the large amount (some 20 to 25 per cent.) of proteid they contain, which is called legumin or vegetable casein. The plant also forms a valuable material for fodder.

Peach. *See* PRUNUS *and* WOODS.

Peach Bloom (*Dec.*) This is not a very definite colour. A mixture usually employed is zinc white added to Venetian red or Indian red.

Peachwood. *See* DYES AND DYEING.

Peacock Blue (*Dec.*) A deep blue of a somewhat greenish hue, but of no definite composition. The usual method is to mix cobalt blue with a little Chinese blue and white.

Peacock Green (*Dec.*) This colour may be made by mixing 50 parts of emerald green, 43 parts of Prussian blue, and 7 parts of white.

Peaked Curve (*Elect. Eng.*) A form of alternating E.M.F. or current in which the curve is steeper than a sine curve. This form of curve indicates that the third partial or component of the curve expressed by Fourier's Series (*q.v.*) is of importance.

Pean (*Eng., etc.*) The PANE (*q.v.*) of a hammer.

— (*Her.*) One of the heraldic furs, the reverse of *erminois*, namely field *sable* powdered *or*. *See under* HERALDRY.

Pea Nut. *See* GROUND NUT.

Pear. *See* WOODS *and* PYRUS,

Pearl (*Typog.*) Type between diamond and ruby in size. *See* TYPE.

Pearl Ash (*Chem.*) *See* ALKALI.

Pearl Essence (*Chem.*) *See* GUANINE.

Pearl Spar (*Min.*) A synonym for Dolomite (*q.v.*)

Pear Push (*Elect. Eng.*) A pendant switch used for electric lights and bells, of which the casing is pear shaped.

Peasemeal (*Foundry*). This is used as a coating on the surface of the sand in complicated moulds; it is afterwards covered with blacking (*q.v.*)

Peat. A deposit of dead vegetable matter which has been left for a long time under such conditions that bacterial action has not been able to bring about the reconversion of the tissues into their original components, CO_2 and water. The factor concerned seems usually to be the continued presence of a thin film of moisture on the dead matter, together with the absence of sunshine. Peat is used for fuel, litter, and also, in a compressed form, as a surgical dressing.

Peck. *See* WEIGHTS AND MEASURES.

Pectolite (*Min.*) A hydrous sodium calcium metasilicate, $H_2O \cdot Na_2O \cdot 4CaO \cdot 6SiO_2$. Pseudo-monosymmetric; usually fibrous, in veins or in radiating masses in basic eruptive rocks. White to

grey or brown. Ayrshire and Midlothian afford many localities. Also from Durham, Skye, Tyrol, New Jersey, etc.

Peculiars (*Typog.*) Accented letters, signs, and special characters for which no provision is made in a compositor's type cases.

Pedal Feed Motion (*Cotton Manufac.*) An attachment to a hopper feeder, and on the skutching machine, for giving a uniform supply of cotton or lap to the beaters.

Pedalier (*Music*). A pedal board (*see* ORGAN) attached to a pianoforte.

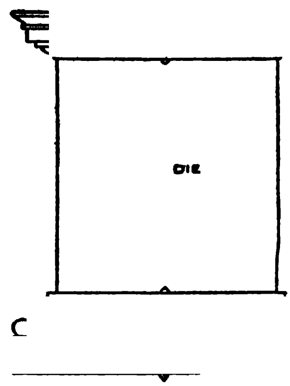
Pedal, Pedal Point (*Music*). A note continued either uninterruptedly or broken by short rests in a part irrespective of the harmonies above or below it. This note may be either at one pitch or changed with its octave. When the pedal is not the lowest part, but appears in an upper part, it is called an *inverted pedal.* The most usual notes for a pedal are the Tonic and Dominant.

Pedals (*Cycle*). *See* CYCLES.

—— (*Music*). (1) The keys of a pedal board. *See* ORGAN. (2) Mechanical contrivances attached to the pianoforte and harp and put into action by the feet. *See* MUSICAL INSTRUMENTS—HARP (*p.* 429) *and* PIANOFORTE (*p.* 431).

Pedersen's Frame (*Cycles*). A light, rigid cycle frame, which has cross stays direct from the top of the head to the bottom bracket.

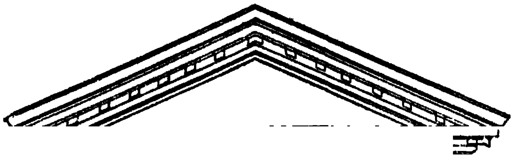
Pedestal (*Architect.*) A feature introduced by the Romans to give greater height to an order without increasing the diameter of the column. It consists of three parts: base; die or dado; cornice or surbase, on which the base of the column stands. The same name is given to a similar form, used to support a statue or other ornament.



PEDESTAL.

—— (*Eng.*) The support or PLUMMER BLOCK serving to support a shaft.

Pediment (*Architect.*) The raking cornices and tympanum forming a termination to the roof of a



PEDIMENT.

classical building. Similar forms are also used over door and window heads in Roman and Renaissance architecture, the same name being given to them.

Pedometer (*Surveying, etc.*) *See* PASSOMETER.

Peel (*Print.*) A contrivance for hanging up printed work to dry on horizontal poles. It consists of a long handle with a broad thin head fitted into one end.

Peeler (*Met.*) *See* RABBLE.

Peeling (*Print.*) *See* OVERLAY.

Peeling of Paint (*Dec.*) This defect is due to insufficient adherence between the paint and the surface to which it is applied. It is most commonly seen where the priming coat is mixed with coarsely ground pigment and an insufficient quantity of oil is used to properly penetrate the wood or cement. Sometimes one coat of paint will peel from another, and to prevent this it is advisable not to allow too much time to elapse between the application of the different coats; in fact, one is best applied over another when the under surface is slightly tacky (*q.v.*)

Peg and Cup Dowels (*Eng.*) Metal DOWELS (*q.v.*) used by pattern makers to connect two parts of a pattern which have to be separated in order to be withdrawn from the mould.

Pegmatite (*Geol.*) A crystalline aggregate of rock-forming silicates, occurring in the form of irregularly lenticular masses traversing gneiss and similar rocks which have been subjected to differential movements at great depths within the Earth's crust while they were in a potentially molten state. Their essential mineral constituents are the same as those of the rock in which they occur; but they are, as a whole, larger grained, which is especially the case towards the centre of the mass. At their outer surfaces pegmatites graduate into the surrounding rock, partly through an interlocking of the crystals on either side of the boundary, and partly through the gradual diminution in the size of the crystals themselves. In no case is there a selvage of finer grained rock along the plane of separation, nor any sharp plane of demarcation between the pegmatite and its enclosing mass, such as exists in the case of most intrusive masses. From this fact it is clear that the rock which encloses the pegmatite must have been at about the same temperature as the latter at the time when consolidation took place. The mineral constitution of pegmatite varies with the composition of the parent rock. In gneisses, or gneissoid rocks allied to granite, the component minerals of the pegmatite are essentially Quartz and the potash felspar Microcline. In the rocks of more basic composition these minerals are represented by Hornblende and the soda-lime felspar Oligoclase. In the case of pegmatites which have been subjected to crushing movements after the earlier stages of consolidation have been passed, some of the Microcline, in the one case, is changed to Muscovite, and part of the Hornblende, in the other, is changed to Biotite. The structure of pegmatite is usually granitic (*q.v.*), as the minerals are generally allotriomorphic (*q.v.*) in relation to each other; but other structures may occur in the acid pegmatites, of which the commonest is that of Graphic Structure. In this, numerous ramifications from large expanses of Quartz crystals closely interpenetrate similar ramifications from equally large expanses of crystals of Microcline. The resulting pattern reminds one of some forms of Oriental writing, whence the name Graphic Granite. Pegmatites are of considerable importance from an economic point of view, not only as ornamental stones, but because such gems as the Topaz and the Emerald occur in them; and because, also, they yield many compounds of the rarer elements, such as Zirconium, Thorium, Cerium, etc.—J. G. G.

Pelagic (*Geol.*) Relating to the deep sea. Correlative with Thalassic and with Littoral, as referring to the conditions under which certain marine strata have been deposited.

Pelasgic (*Architect.*) The art of Greece before the first olympiad (B.C. 776, the beginning of authentic Greek history) is known as Pelasgic art, as it was probably the work of the Pelasgi, the early inhabitants of Greece. The principal remains of Pelasgic art are: (1) Massive walls, formed of rough masses of rock, of rectangular blocks, or of polygonal blocks. (2) Underground chambers, such as the well known "Tholos (or Treasury) of Atreus." This consists of a circular vaulted chamber of stone, about 50 ft. diameter and about the same height, buried under a tumulus, and reached by means of a stone walled passage or dromos (*q.v.*) (3) The Lion Gate at Mycenæ. *See* THOLOS.

Pellet Moulding (*Architect.*) An enriched Norman moulding consisting of a series of small spherical forms in a hollow mould.

Peltier Effect (*Elect.*) If a current flow across the junction of two metals, heat is either absorbed or liberated, according to the direction of the current. The amount of the heat developed or absorbed is proportional to the current, thereby differing from the heat produced in accordance with Joule's Law (*q.v.*)

Pencil. A term sometimes applied to a small camelhair brush. *See* PENCILS.

—— (*Light*). A collection or "bundle" of rays of light, either parallel, convergent, or divergent; a narrow beam of light.

Pencil Gauge (*Join.*) A small piece of wood, notched, and used to guide a pencil when marking a line parallel to the edge of a piece of wood which is to be chamfered.

Pencils (*Dec.*) Small brushes used by decorators and sign writers, of various forms, provided with long handles. When the pencils are held in a quill ferrule the sizes are indicated by the size of quill, such as crow, duck, goose, swan, etc. Red and brown sables, camelhair writers, and short sables are the principal pencils used by the decorator. *See* PAINTERS' BRUSHES.

Pendant (*Architect.*) A hanging ornament used in the roofs and vaults of Perpendicular Gothic architecture. *See* FAN VAULTING.

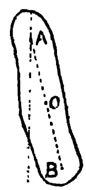
—— (*Build.*) A bracket or apparatus hanging from a roof or ceiling for lighting by gas, etc.

Pendentive (*Architect.*) The portion of a circular dome which descends into a corner of the square over which the dome is constructed. Circular domes are constructed over square spaces in this manner in Byzantine architecture (*q.v.*)

Pendulum. A SIMPLE PENDULUM consists of a heavy particle, suspended by a weightless and absolutely flexible thread. If the pendulum swing through a small arc, the particle will describe approximately a Simple Harmonic Motion (*q.v.*), and the time of a complete vibration is given by the equation

$$T = 2\pi\sqrt{\frac{l}{g}}$$

where l is the length of the pendulum, and g the acceleration due to gravity. If a rigid body of any shape be free to swing about a frictionless support (*e.g.* knife edges) at A, then it will oscillate in the same time as a simple pendulum of lesser length, AB. The point A is termed the CENTRE OF SUSPENSION, and B the CENTRE OF OSCILLATION. These two points are interchangeable, so that if the body be suspended from B, then A becomes the centre of oscillation. If the body be struck a blow at its centre of oscillation, it will turn about its axis of suspension, but there will be no pressure produced at the axis. From this fact the centre of oscillation is also termed the CENTRE OF PERCUSSION. The time of a complete vibration of a compound pendulum is given by the equation



PENDULUM.

$$2\pi\sqrt{\frac{K}{C}}$$

in which T is the time in seconds, K the Moment of Inertia of the body about the axis of suspension, and C the ratio of the restoring couple exerted by gravity on the body when displaced through a small angle, to the angle through which it has been displaced. Let m be the mass of the body, O the Centre of Gravity, and let the distance $AO = h$; if θ = the angle through which the body is turned, the force due to gravity is mg, acting through O, and its moment about A is $mgh \sin\theta$. Then

$$C = \frac{mgh \sin\theta}{\theta}$$

or $C = mgh$ if θ be a small angle. Let the moment of inertia about an axis through O be mk^2; then the moment of inertia about an axis through A is

$$K = mk^2 + mh^2$$

The time of vibration is therefore

$$T = 2\pi\sqrt{\frac{mk^2 + mh^2}{mgh}}$$

$$T = 2\pi\sqrt{\frac{k^2 + h^2}{gh}}$$

It thus swings in the same time as a simple pendulum of length $\frac{k^2 + h^2}{h}$. KATER'S PENDULUM consists of a bar furnished with two sets of knife edges, one or both of which can be adjusted in position. Positions are found by trial, in which the time of vibration of the pendulum is the same about both knife edges. The distance between the edges is then equal to the length of the equivalent simple pendulum, and if the time of swing be correctly known, the value of g can be obtained with great accuracy. A very small difference in the times of swing about the different knife edges can be allowed for in calculating the results. As the time of swing of a pendulum depends upon its length, it is important in the case of clocks that this shall vary as little as possible; to ensure this result, COMPENSATED PENDULUMS are used. HARRISON'S GRIDIRON PENDULUM has the bob suspended by a framework composed of iron and brass rods, so adjusted in length that the expansion of the brass rods raises the bob as much as that of the iron rod lowers it, the effective length thus remaining constant. In other cases the framework is superseded by concentric tubes of iron and zinc, as in the case of the clock at the Houses of Parliament. In the MERCURIAL PENDULUMS of GRAHAM and DENT the bob consists of a tube containing mercury, whose upward expansion counteracts the downward expansion of the rod.

Pendulum Governor (*Eng.*) The ordinary governor is often so called. The hinged rods carrying the balls are sometimes termed pendulums. *See* GOVERNORS.

Pendulum Spring (*Clocks*). A short thin flexible strip of steel supporting the pendulum, and containing the centre about which it vibrates.

Pene. *See* PANE.

Penetration Twins (*Min.*) Twinned crystals which have no common plane and which mutually penetrate each other. The part in common has a very complex molecular structure, but the free portions retain the symmetrical arrangement. *See* TWINNING.

Penistone Flagstones. *See* BUILDING STONES.

Pennon. A small narrow flag terminating in either one or two points, formerly carried by knights at the end of their lance or spear, and usually bearing a device or the arms of the knight.

Pennyweight. *See* WEIGHTS AND MEASURES.

Penrith Sandstone. *See* BUILDING STONES.

Penstock. A trough or conduit for water, made of boards. The sluice above a water wheel.

Pentachord (*Music*). A succession of five diatonic sounds scalewise.

Pentamethylenediamine (*Chem.*) *See* CADAVERINE.

Pentanes (*Chem.*) C_5H_{12}. There are five compounds of this formula; their names, constitution, and boiling points are given under PARAFFINS. They are all colourless liquids of agreeable smell, and possess the general properties of the Paraffins. Normal pentane burns with a luminous flame, and is used as a standard light in testing the illuminating power of coal gas.

Pentane Standard. A light obtained by burning pentane (*q.v.*) in a particular form of lamp, to serve as a standard of illumination in photometric work. The Harcourt Lamp burns one volume of liquid pentane to 576 volumes of air; the burner is $\frac{1}{4}$ in. diameter and the flame $2\frac{1}{2}$ in. high; the light is then equal to one British Standard Candle (*q.v.*)

Pentaptych (*Art*). A painted or carved panel or screen, consisting of five leaves, which fold over each other. *Cf.* TRIPTYCH.

Pentastyle (*Architect.*) The name given to a temple which has five columns in the front row. *See* HEXASTYLE, OCTASTYLE, DISTYLE, *and* DECASTYLE.

Pentelic Marble. *See* MARBLE, STATUARY.

Pentosans (*Chem.*) Anhydride-like derivatives of the Pentoses.

Pentoses (*Chem.*) Sugars containing five carbon atoms. Examples are arabinose (*q.v.*), xylose (*q.v.*) *See also* SUGARS.

Penumbra. The partial shadow beyond and adjoining the total shadow which is caused by an opaque body intercepting light from a luminous body. In art, the point or boundary at which light blends with shade.

—— (*Astron.*) A half shadow which surrounds the deeper shadow of the earth: the umbra of a sunspot or the shadow of the moon.

Peplum (*Archæol.*) A cloak or shawl longer and of finer material than the pallium (*q.v.*), worn by Greek and Roman women.

Pepper (*Botany*). The dried unripe berry of *Piper nigrum* (order, *Piperaceæ*) constitutes Black Pepper, and, on removal of the rind, White Pepper.

Peppermint (*Botany*). The essential oil is distilled from the leaves of the fresh plant *Mentha piperita* (order, *Labiatæ*). *See* LABIATÆ.

Pepsin (*Chem.*) That constituent of the gastric juice which hydrolyses proteids, converting them finally into peptones; it is a solid precipitated from solution by ammonium sulphate. It contains carbon, hydrogen, nitrogen, oxygen, sulphur; but nothing is known of its chemical constitution.

Peptones (*Chem.*) The final products of hydrolysis of proteids by pepsin; they can also be obtained by hydrolysing proteids by dilute acids or by superheated steam. Soluble in water, insoluble in alcohol, easily diffuse through animal membranes, give the Biuret reaction, give precipitates with the alkaloid reagents, not coagulated by heat.

Per (*Music*). By, as *per recti et retro*, by forward and backward motion. Dr. Crotch's Double Chant in G is a good example, where Part 3 is the reverse of Part 1, and Part 4 the reverse of Part 2 in all four voices.

Percarbonates (*Chem.*) *See* POTASSIUM COMPOUNDS.

Percentage Conductivity (*Elect. Eng.*) The ratio (expressed as a percentage) of the conductivity of a given copper wire to that of a similar wire made of pure copper.

Perching (*Leather Manufac.*) A similar process to staking, but in perching the skin is fixed to a horizontal pole (the perch), and is worked over on the flesh side with a "crutch stake," a tool fixed on a handle like a crutch.

Perchlorates and Perchloric Acid (*Chem.*), R^IClO_4. The perchlorates are salts of perchloric acid. The acid is a white crystalline solid which melts at 15°. It is deliquescent; forms a hydrate with one molecular proportion of water. It decomposes on keeping and with explosive violence on heating or on contact with organic matter. It is obtained by distilling potassium perchlorate with concentrated sulphuric acid. It is a monobasic acid; its most important salt is potassium perchlorate, $KClO_4$. The salt is obtained by heating potassium chlorate till it has lost about a fifth of its oxygen, when it forms a nearly solid mass. The mixture of chlorate, perchlorate, and chloride is washed with water to remove chloride, then warmed with hydrochloric acid to decompose chlorate. From the residue pure potassium perchlorate can be obtained by crystallisation. It is a white crystalline solid, isomorphous with potassium permanganate, sparingly soluble in water, insoluble in absolute alcohol.

Probable constitution, $O = \overset{\overset{\displaystyle O}{\|}}{\underset{\underset{\displaystyle O}{\|}}{Cl}} - OK$. All other perchlorates are soluble in water. All perchlorates on heating give a chloride and oxygen. They are not reduced by sulphur dioxide.

Perclose. *See* PARCLOSE.

Percussion (*Music*). *See* HARMONIUM, *p.* 442.

——, **Centre of** (*Phys.*) *See* PENDULUM.

Perdendosi (*Music*). Gradually softer and slower.

Perennial (*Botany*). Living more than two years: the term may be applied to a plant as a whole, or to certain parts, *e.g.* the root or stem. A plant whose stem dies down annually, while the roots remain alive, is termed a HERBACEOUS PERENNIAL.

Perfect (*Music*). A term applied to the intervals of the 4th, 5th and octave. Perfect intervals are so called because they are changed from consonant to dissonant intervals when augmented or diminished. This is not the case with the other intervals: 2nds and 7ths are dissonant intervals in both the major and minor form, whilst 3rds and 6ths are consonant intervals in both the major and minor form. *See also* CONCORD *and* INTERVAL. The term is also applied to the cadence having the chord progressions Dominant to Tonic. *See* CADENCE.

Perfect Cadence (*Music*). *See* CADENCE.

Perfect Engine (*Phys.*) A theoretically perfect engine is one which converts a certain definite fraction of the heat supplied to it into mechanical work. If W be the work done, H the heat supplied (measured in mechanical units), θ_1 and θ_2 the absolute temperature of the working substance at the time that it enters and leaves the cylinder respectively, then

$$\frac{W}{H} = \frac{\theta_1 - \theta_2}{\theta_1}$$

Thus, if the working substance enter a cylinder at 200° C. and leave it at 100° C., we have $\theta_1 = 273 + 200 = 473°$, $\theta_2 = 373$, and a perfect engine will convert the fraction $\frac{100}{473}$ of the energy supplied to it in the form of heat into mechanical work. This fraction or ratio is termed the EFFICIENCY of the engine.

Perfecting Engine (*Paper Manufac.*) A conical shaped vessel, fitted internally with revolving knives, used for beating pulp.

Perfecting Machine (*Print.*) *See* TYPOGRAPHY.

Perfect Paper (*Print.*) Reams made up to the full number of 516 sheets.

Perfect Up (*Print.*) Printing the second side of a sheet of paper.

Perforated Bars (*Lace Manufac.*) Thin ribbons of the highest quality of steel, in thickness 100 and upwards to the inch. Holes are pierced in them at certain well defined and accurate distances for the reception of the warp threads. Invented by Mr. (afterwards Sir James) Oldknow to supersede bars with attached guides.

Perforated Bricks (*Build.*) Bricks having a number of holes through them; used for ventilation.

Perforated Pulley (*Eng.*) A pulley whose rim is pierced by a number of small holes; these holes allow the layer of air which is enclosed between the belt and the periphery of the pulley to escape, and bring the belt into closer contact with the metal, thereby diminishing the amount of slip.

Perforator (*Elect. Eng.*) The instrument used for perforating or punching the holes in a paper strip used for transmitting messages by automatic telegraphic instruments (Morse, etc.)

Perianth (*Botany*). The outer floral leaves in the flower. It usually consists of an outer green calyx and an inner coloured corolla.

Pericarp (*Botany*). The term applied to the wall of the ripened ovary in the fruit. In the "stone fruits," such as cherry and plum, it is divisible into three layers: the rind, or epicarp; the pulp, or mesocarp; the stone, or endocarp.

Periclase (*Min.*) Native magnesia, MgO. Cubic, in dark octahedra and greenish grains in metamorphosed limestone from Monte Somma. It usually contains traces of ferrous oxide.

Pericline (*Min.*) A variety of Albite (*q.v.*), twinned in a particular way, in white turbid crystals elongated along the *b* axis.

Peridot (*Min.*) A synonym for Olivine. Peridot is one of the names by which jewellers designate Olivine.

Perigee (*Astron.*) The Sun (or Moon) is said to be in Perigee when its distance from the Earth is least. *Cf.* APOGEE.

Perihelion (*Astron.*) The position of the earth, planet, or comet when nearest to the sun.

Period (*Music*). A complete musical sentence divided into two parts at least, the former of which generally ends with a half close or some form of middle cadence, and the latter with a full cadence. The subdivisions are called phrases.

—— (*Phys.*) The time occupied by a complete movement or cycle of operations; *e.g.* the time of swing of a pendulum, or the time taken by a complete alternation of an alternating electric current.

Periodates and Periodic Acid. (*Chem.*) The normal periodic acid HIO_4 is an unstable solid obtained by heating orthoperiodic acid at 100° under very low pressure (15 mm.); it decomposes on further heating into the pentoxide, water, and oxygen, without forming the heptoxide I_2O_7 which corresponds to this acid. Orthoperiodic acid, H_5IO_6, the common acid, is a white crystalline solid which melts at 133°, and decomposes at 140° like the normal acid. It is obtained from its disilver salt $Ag_2H_3IO_6$ by acting upon it with water, $5Ag_2H_3IO_6 = 3H_5IO_6 + 2Ag_5IO_6$. Many periodates are known, and they can all be regarded as derived from various hydrates of the heptoxide I_2O_7:

$$I_2O_7 + H_2O = 2HIO_4$$
Metaperiodic Acid (Normal Acid).

$$I_2O_7 + 3H_2O = 2H_3IO_5$$
Mesoperiodic Acid.

$$O = 2H_5IO_6$$
Orthoperiodic Acid.

Sodium orthoperiodate is obtained as a sparingly soluble solid by passing chlorine into a mixture of sodium iodate and hydroxide dissolved in water:

$$Na_2I_2O_6 + 6NaOH + 2Cl_2 = 4NaCl + 2Na_2H_3IO_6.$$

The silver salt referred to above can be obtained by suspending this sodium salt in water; add just enough nitric acid to dissolve it and then silver nitrate, when the pale yellow disilver hydrogen periodate separates. The salt Ag_5IO_6 is a black crystalline powder. The periodates when heated give oxygen and an iodide.

Periodic Current. An ALTERNATING CURRENT.

Periodicity (*Phys., Elect. Eng., etc.*) The FREQUENCY (*q.v.*) of any recurring operation.

Periodic Motion (*Phys., etc.*) A motion which is repeated in definite regular intervals of time, *e.g.* the swing of a pendulum or the vibrations of a sounding body.

Periodic Perturbations (*Astron.*) Slight disturbances in the position of the Earth in its orbit which take place periodically.

Periodic System. A method of arranging the elements so as to exhibit their properties as a periodic function of their atomic weights. All the commoner elements are included in the subjoined Table 1, arranged in the order of their atomic weights. A very few of the less common elements are included for reference. Where dashes occur, rare elements are known which take these places; where no element and no dash occur, there is either no element known at all or the place has been assigned to some imperfectly studied element. Hydrogen is omitted, as it does not fit into any group at the present time. The vertical rows will be referred to as SERIES, the horizontal rows as GROUPS. A group contains allied elements. Each group can be divided into two SUB-GROUPS, each containing elements more closely allied to each other than they are to the other members of the group. For example, in Group II. Calcium, Strontium, Barium are very closely allied to each other, and they constitute the odd series; while Magnesium, Zinc, Cadmium, and Mercury are fairly closely allied; and there is a general resemblance between all the members of the group. The elements are also arranged fairly well according to their valency, as the table shows.

	1	2	3	4	5	6	7	8	9	10	11
I.	Li 7	Na 23	K 39	Cu 63	Rb 85	Ag 108	Cs 133			Au 197	
II.	Be 9	Mg 24	Ca 40	Zn 65	Sr 87	Cd 112	Ba 137			Hg 200	Ra 225

Group I.	R_2O	RCl
II.	$*R_2O_2$	RCl_2
III.	R_2O_3	RCl_3
IV.	RO_2	RCl_4
V.	R_2O_3, R_2O_5	RCl_3, RCl_5
VI.	R_2O_2 RO_3	RCl_2, RCl_6
VII.	R_2O, R_2O_7	RCl, RCl_7

When a curve is drawn having atomic weights as abscissae and melting points as ordinates, a series of alternate minima and maxima are obtained, and the elements which form the minimum and maximum points are all in Groups I., IV., VII., or VIII. Example:

Minima Li F Cl Br Cs
Maxima C Si Mn Ru

In the first two series the maxima are in Group IV.; these two series are called SHORT SERIES; series 3 and 4, 5 and 6, 9 and 10 are called LONG SERIES, and between the two series which compose a long series are the so-called TRANSITIONAL ELEMENTS—groups of three elements, the members of which are closely allied to each other. Besides the periodicity of the melting point, the atomic volumes of the elements vary periodically with the atomic weights, and in such a way that generally the atomic volume is a minimum where the melting point is a maximum, and *vice versa*. Other properties of the elements are also more or less periodically variable with the atomic weights, such as the heat of formation of the halogen salts; also the spectral lines of elements in the same group show relationships, *e.g.* those of Magnesium, Calcium, and Strontium, and those of Zinc, Cadmium, and Mercury of Group II. The system also divides the elements into metals and non-metals fairly well; if a triangle be drawn between the points A, B, C in Table 1, it includes the Non-Metals and two metals Chromium and Manganese (as Table 2). Chromium resembles the non-metals in its trioxide and compounds derived from it, and manganese in forming permanganates which are isomorphous with the perchlorates. The new elements of no valency must be regarded as forming transitional elements between the strongly basic elements of Group I. and the strongly acid elements of Group VII.; thus before Lithium comes Helium, and between Fluorine and Sodium comes Neon, between Chlorine and

Potassium Argon, between Bromine and Rubidium Krypton. The system is not by any means perfect. Tellurium must be placed in Group VI., although it has a higher atomic weight than iodine; Manganese is out of place in Group VII.; Argon must be placed before Potassium, although it has a higher atomic weight than the metal. The periodic system has been of use in controlling atomic weights and in predicting the existence and even the properties of new elements. Many attempts have been made to account for the periodicity of the properties of the elements; one of the most recent of these, due to Professor Emerson Reynolds, will be found in the Chemical Society's *Journal* for 1902, p. 612; an account of the most recent attempt, due to Professor J. J. Thomson, will be found in *The Recent Development of Physical Science*, by W. C. D. Whetham, p. 258.

B

TABLE 2.

Peripheral Velocity. The linear velocity (*q.v.*) of a point in the circumference of a revolving wheel, etc., as distinguished from the angular velocity of the wheel.

Peri-Position (*Chem.*) *See* NAPHTHALENE.

Peripteral (*Architect.*) The name given to that form of temple which is surrounded by a range of columns. *See* PSEUDO-PERIPTERAL.

Periscope (*Optics*). An optical device by which a view in a horizontal direction may be obtained by looking through a vertical tube. Such a device is used on submersible boats to enable a look out to be kept when running just below the surface of the water.

Periscopic Lens (*Light*). A MENISCUS LENS (*q.v.*)

Peristerite (*Min.*) A variety of albite showing a play of colours.

Peristylium (*Architect.*) A court or square having a colonnade on each of its four sides. This colonnade and also a colonnade surrounding a temple are known as peristyles. In a Roman house the peristylium is the inner court, and, like the atrium, the central part of it is open to the sky. *See* COLONNADE, PORTICO, *and* PTERA.

Perkins' Reaction (*Chem.*) Aromatic aldehydes undergo condensation with sodium salts of fatty acids in presence of the anhydride of the acid. This is Perkins' Reaction. The acid anhydride withdraws water from the aldol compound formed by the union of the aldehyde and fatty acid salt. Example:

$$C_6H_5C\left\langle\begin{matrix}O\\H\end{matrix}\right. + CH_3COONa = C_6H_5C\left\langle\begin{matrix}OH\\CH_2.COONa\\H\end{matrix}\right.$$

Benzaldehyde. Sodium Acetate.

$$C_6H_5C\left\langle\begin{matrix}OH\\CH_2COONa\\H\end{matrix}\right. - H_2O = C_6H_5CH = CH.COONa.$$

Sodium Cinnamate.

The reaction has received many applications; dibasic acids may be used as well as monobasic acids, and the acid anhydride need not be that corresponding to the acid salt. Other examples will be found under COUMARIN and NAPHTHALENE.

Perlite (*Chem., Met.*) *See* IRON.

—— (*Geol.*) A variety of vitreous rock of eruptive origin which has cooled in such a manner as to form a series of curved cracks, which break the rock up into small spheroids, the "pearls."

Permanent Hardness. *See* WATER, CALCIUM COMPOUNDS, *and* CLARK'S PROCESS.

Permanent Load (*Eng.*) (1) A load on any structure which is unvarying in amount or position. (2) The constant work performed by an engine or motor.

Permanent Magnet. *See* MAGNET.

Permanent Set (*Eng.*) When any body is strained beyond its elastic limit (*q.v.*), and therefore does not recover its original form or dimensions when the stress is removed, it is said to have received or acquired a permanent set.

Permanent Way (*Civil Eng.*) The ordinary railway track, consisting of BALLAST, RAILS, and SLEEPERS, laid on a properly prepared surface or formation level. *See also* RAILWAYS.

Permanent Way Crane (*Eng.*) A crane mounted on a railway track. Used for repairs to a line and removal of debris after an accident.

Permanent White (*Dec.*) The best quality of artificial barytes or blanc fixe (*q.v.*), which, when ground in water, is quite permanent. When used in oil, one part is mixed with two parts of oxide of zinc (*q.v.*)

Permanganates (*Chem.*) *See* MANGANESE COMPOUNDS.

Permeability, Magnetic (*Elect.*) The ratio between the number of lines of force (per unit area) running through a piece of magnetisable material—*i.e.* the MAGNETIC INDUCTION B—and the MAGNETISING FORCE H which produces them. The permeability μ is thus given by the equation

$$\mu = \frac{B}{H}$$

For non-magnetic materials B is practically unity. For iron, etc., its value varies very greatly, and depends on the magnetisation, decreasing as the latter increases. It is also affected by the previous treatment of the iron. The following values of the

permeability for different values of B are given by Hopkinson for a good specimen of annealed soft iron;

B	
5,000	3,000
10,000	2,000
15,000	526
20,000	30

Permeameter (*Elect. Eng.*) A simple form of instrument for measuring the PERMEABILITY (*q.v.*) of a bar or rod of iron.

Permeanance (*Elect.*) The reciprocal of the RELUCTANCE (*q.v.*)

Permian (*Geol.*) A series of rocks in which the prevailing colour is red, occurring in the kingdom of Perm, in Russia, and usually regarded as pertaining to a geological horizon intermediate between that of the Carboniferous and the Trias. The rocks in Britain called by this name belong partly to the Carboniferous Rocks (stained red by infiltration of iron from the New Red Rocks), partly to a separate formation, which forms the lower part of the New Red Rocks, and is virtually conformable to the overlying Trias, and at the same time is violently unconformable to all the rocks older than itself. This formation was for a long time called the Lower New Red, or Dyas, and the former name is now coming again into general use. Where the Lower New Red is typically developed, as in North Westmorland, it consists of three members: the Penrith Sandstone, with associated breccias at the base (all of desert origin); above that, the Plant Beds and Marl Slate; and, finally, the Magnesian Limestone. The Bunter Marls which succeed belong to the Trias, and lie with a slight unconformity upon the beds below. In Germany, where these rocks attain considerable commercial importance on account of the occurrence in them of Gypsum and Rock Salt, copper is worked in the Marl Slate, which lies upon the Unter Rotheliegende, one of the higher members of the Upper Carboniferous Rocks of those parts. The most conspicuous member of the so-called Permians in Britain is the Magnesian Limestone, which yields an interesting suite of marine fossils. In the Alps and in the Mediterranean countries the equivalents of the Lower New Red, Dyas, or "Permian" are of marine origin, and yield, amongst other fossils, a large number of species of the earliest types of Ammonites.

Pernot's Revolving Furnace (*Met.*) A furnace with a flat but slightly sloping hearth, which revolves slowly, thus thoroughly mixing the molten metal and exposing it to the action of the flames. It is used on the Continent for steel making by an OPEN HEARTH PROCESS (*q.v.*) *See also* METALLURGY.

Perpendicular. (1) At right angles to a line or plane. (2) Often used as synonymous with VERTICAL.

—— (*Architect.*) One of the periods into which English Gothic architecture is divided. It extended from about 1377 A.D. to 1547 A.D., and is also known as RECTILINEAR GOTHIC. The work of the later part of the period is known as the TUDOR STYLE or FLORID GOTHIC. The principal features of the work of the Perpendicular period are: (1) SHALLOW MOULDINGS, with casements, bowtells, and double ogees. The characteristic ornaments are the Tudor Flower and the Tudor Rose. (2) OCTAGONAL CAPITALS are used with circular shafts, and pier mouldings are frequently carried up into the arch without the intervention of a capital. (3) PANELLING, extensively used on wall surfaces, particularly late in the period. (4) The WINDOWS are very large, frequently taking up almost all the width between the buttresses. Tiers of transoms are used, and the mullions are carried up vertically to the window arch. (5) The TRIFORIUM is reduced to a minimum. (6) The ARCHES are frequently very depressed later in the style, the four-centred arch being a common form. (7) The BUTTRESSES are of large projection, flying buttresses being extensively used. (8) The type of VAULTING used in this style, known as fan vaulting, was a complete departure from the forms which obtained in the preceding periods. (9) The FOLIAGE is of a more conventional type than that of the Decorated period. *See* DECORATED.

Perpends (*Build.*) The vertical joints on the face of brickwork.

Perron (*Architect.*) A French term denoting (1) an external flight of steps at the entrance to a building, giving access to a storey which is raised above the level of the ground. (2) A balcony landing in a similar position with a flight of steps at each end.

Perseids (*Astron.*) A shower of meteors or shooting stars which appears to "shoot" from the constellation of Perseus. The shower recurs every year in the month of August.

Persian (*Leather*). Sheep and goat skins tanned in India with Turwahr bark are imported in large quantities to this country, and are known as PERSIAN SHEEP or PERSIAN GOAT.

Persian Green (*Dec.*) A name sometimes used in connection with Oriental decoration to designate the pure, bright, or vivid green known in the form of a pigment as "emerald green" (*q.v.*) It is almost identical in hue with the primary green in the solar spectrum.

Persians (*Architect.*) *See* ATLANTES.

Persienne (*Build.*) A frame or shutter attached to the outer side of a window, and having slips of wood fixed in the same way as a louver board (*q.v.*)

Personal Equation (*Phys., etc.*) An error due to the idiosyncrasies of a particular observer or experimenter. In a trained observer this error becomes nearly constant, and can be eliminated or accurately allowed for in calculations based on the observations.

Perspective (*Art*). The art of representing by a drawing made on a flat surface solid objects or surfaces not lying in the plane of delineation; the representation of objects as they appear to the eye. In painting, the art of conveying the impression of depth and distance by correct drawing and judicious colour tones and shadows.

——, **Ærial.** The suggestion or expression of distance in a picture by the medium of atmosphere. "The expression of space."—*Ruskin.*

——, **Linear.** The branch of perspective that deals with form and magnitude.

Persulphates and Persulphuric Acid (*Chem.*) *See* POTASSIUM COMPOUNDS *and* SULPHUR COMPOUNDS.

Perturbations (*Astron.*) Variations in the path or orbit of a planet, due to the attractions of other bodies as they approach or recede.

Pesante (*Music*). Heavily, firmly.

Pestle (*Paint.*) An instrument, generally in the form of a truncated cone, the base being a plane surface. Used for grinding pigments.

Pet Cock (*Eng.*) A small tap fitted to the ends of cylinders in steam engines to enable water to escape before the engine is started.

Peterhead Granite. *See* BUILDING STONES.

Petersburg Standard (*Carp. and Join.*) A measure of timber. 120 pieces 12 ft. × 11 in. × $1\frac{1}{2}$ in. = 165 cubic ft.

Petit's Wheel (*Chem. Eng.*) Used in stearine manufacture. A jacketed drum cooled by the circulation of refrigerated brine. The lower portion of the drum dips into a bath of melted fatty acids, and, as it revolves, crystals of stearine separate and are removed before the periphery passes into the bath again. Compare SEEDING.

Petrol. *See* PETROLEUM.

Petrol Engine *or* **Motor.** Under this term are included engines in which the motive power is obtained by the combustion or explosion in the cylinder of vapour derived from an oil or spirit of a more volatile nature than those used in Oil Engines proper (*q.v.*) As such engines are very frequently driven by the mixture of light oils known in the trade as petrol, the name Petrol Engine or Motor has been commonly applied to them in England and France; in the United States they are more often termed Gasoline Motors. They are distinguished from oil engines by the much greater speed at which they run, their consequent smaller size (for any given horse power), and their adaptability to circumstances in which great portability is essential In the most usual types there is no bedplate, the cylinder being bolted to a crank case, which also carries the bearings of the crank shaft.

The main principles of the construction of a small motor (such as is used on motor cycles) are shown in fig 1, which represents a cross section of a single cylinder engine with air cooling; a side view is given in fig. 2. A is the cylinder, in which moves the piston B; the connecting rod C is attached to the piston by a cross head D, and to a crank formed by a pin E, which is fixed to the two wheels F, F. These wheels form the flywheels of the engine, and are mounted on a divided shaft, of which the two halves G and H are supported in bearings in the side of the crank chamber K. The latter is often composed of aluminium castings, bolted to the cylinder at L, and attached to the frame by a lug M. The shaft G carries the pulley by which motion is transmitted to the driving rim of the back wheel of the cycle. The shaft H transmits motion to the HALF SPEED SHAFT N through a pair of toothed wheels O, which cause N to revolve at half the speed of H. The half speed shaft carries two cams, P and Q, shown on a larger scale in fig. 4. The cam P acts on the rod R, and opens the EXHAUST VALVE S, which is closed again after the cam passes the position in which it engages the end of R by a spring on the valve rod. T is the ADMISSION VALVE, also kept closed by a spring on its spindle; U is the SPARKING PLUG (given on a larger scale in fig. 5). The cylinder A and cylinder head V are provided with projecting ribs, which afford a large radiating surface, by means of which the cylinder is cooled. The tube W communicates with the VAPOURISER or CARBURETTOR, in which the explosive mixture is produced, by mixing vapour derived

from petrol or motor spirit with air; this apparatus is either a SPRAY CARBURETTOR or a SURFACE CARBURETTOR (*q.v.*) X is the EXHAUST PIPE leading to the SILENCER, a chamber from which the products of combustion escape into the air through a number of openings. This arrangement deadens the sound produced by the sudden release of the gases. The action of this engine is as follows: At the commencement of the cycle or series of operations the valves S and T are both closed; the piston descends, and the vacuum created in the clearance space V causes the valve T to be opened by the pressure of the mixture (*i.e.* the explosive gas) in the tube W. The CHARGE of explosive gas is thus drawn into the cylinder during the descent of the piston; as the latter approaches the end of its stroke the valve T closes, and during the up stroke, which is the second stroke of the cycle, the mixture is compressed, both valves remaining closed. As the next down stroke (the third stroke of the cycle) commences, the mixture is fired or ignited by a spark produced at the gap between the projecting wires at the end of the sparking plug U. The explosion causes an impulse to be given to the piston, which moves downward, performing its WORKING STROKE. At the end of this stroke the shaft N has turned round into such a position that the cam P engages the end of the rod R, which it raises, and so opens the exhaust valve S. During the second up stroke (or fourth stroke of the cycle) the products of combustion escape by the pipe X, and at the end of the stroke the cam P ceases to act on the rod R, which drops back into its original position, and the valve S closes, ready for the cycle of operations to begin over again. The production of the spark requires further explanation. A diagram of the electrical connections is given in fig. 3. A is the accumulator, usually consisting of two cells, giving an E.M.F. of about four volts when charged. From one terminal of this a wire goes to one terminal B of the primary of an induction coil (*q.v.*), from the other terminal of which C, a wire, leads to D, where the current enters the CONTACT BREAKER (fig. 4). It now flows from D along an insulated conductor H to the platinum tipped screw E, at which point the circuit has to pass from the

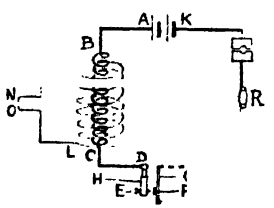

FIG. 3.—DIAGRAM OF ELECTRIC CIRCUIT.

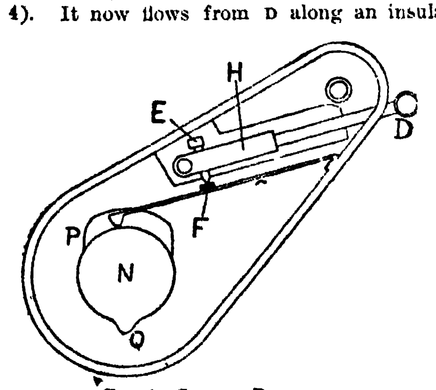

FIG. 4.—CONTACT BREAKER.

screw to the TREMBLER or spring G, on which is fixed a small platinum contact piece F. Between E and F there is a small gap, across which the current is unable to pass until the trembler is raised by means of the cam Q on the half speed shaft. The position of the cam is so adjusted that the contact is made at the time when the working stroke of the engine is commencing. At this instant the current can flow from E to F, through the trembler G, and through the frame of the machine to a switch R (fig. 3) contained in one of the handles of the machine. From this switch an insulated wire carries the current through a plug switch J back to the terminal K of the accumulator, thus completing the primary circuit. The secondary circuit, in which the spark is actually produced, is simpler; M and L are the terminals of the secondary of the induction coil, and are connected to the two platinum wires N and O of the SPARKING PLUG shown on an enlarged scale in fig. 5. A well insulated wire from one terminal of the secondary, L, runs to a metal cap A, fixed at the end of a porcelain cylinder B; through this runs a wire, terminating in the bent elbow O. The plug has a metal mount C, by means of which it can be screwed into the aperture provided at the head of the cylinder (fig. 1). This metal carries the other wire N, which is therefore connected to the engine and frame of the machine, through which the secondary circuit is completed. The portions of both circuits which are formed by the frame are shown in fig. 3 by broken lines. The primary current, which only commences to flow when the circuit is completed by the movement of the contact breaker, is interrupted suddenly when the cam Q (fig. 4) releases the end of the trembler G, and this sudden interruption of the primary current induces an electromotive force in the secondary circuit, which is sufficiently high to cause a spark to leap across the gap N O between the wires of the sparking plug. The primary current can be cut off entirely, and the sparking stopped either by the handle switch R (fig. 3) or by the plug switch J. When the rider dismounts for a time, or leaves the machine, it is usual to take out the plug from the latter switch and keep it in the pocket; in the absence of the plug the current cannot be accidentally turned on. The exact instant at which the spark occurs is of great importance. When the engine is running fast, ignition must occur earlier than when running slowly. The timing of the spark is effected by turning the contact breaker through an angle by means of a rod attached at one end to the case of the contact breaker, and at the other to a small handle placed within easy reach of the rider. *See* MOTOR CYCLES. By this means the cam Q (fig. 4) comes into contact with the spring G earlier or later, as may be required, and therefore the time at which the spark occurs can be controlled.

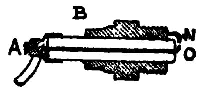

FIG. 5. SPARKING PLUG.

Larger engines are constructed on a somewhat different plan, though the main principles are essentially the same. Two or four cylinders are often employed, or in some cases even more. Diagrams of a two cylinder engine (De Dion type) are given in figs. 6 and 7. The cylinders are each surrounded by a water jacket or space through which flows water, shown by dotted lines. From the jackets the water is led by pipes to a RADIATOR or cooler, an arrangement of tubes provided with external gills of metal, whose function is to increase the radiating surface. The water is then returned to a tank or reservoir,

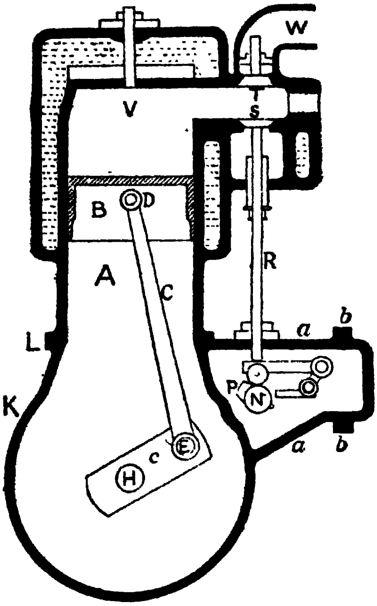

Fig. 6.

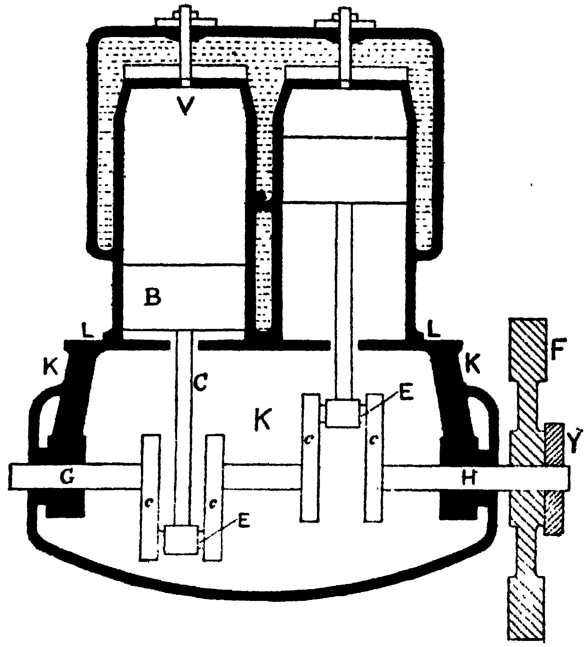

Fig. 7.

Two-Cylinder Water-Cooled Engine.

from which it again flows to the water jackets, the flow being maintained in most cases by a pump worked by the engine. The cranks *c*, *c* are forged or built up, and the flywheel is fixed on a projecting end of the crank shaft outside the cylinder. There is no driving pulley, but the power is transmitted either by some form of clutch Y (fig. 7) or in other cases by gearing on the crank shaft. The half speed shaft N is contained in a chamber *a*, *a* outside the crank chamber K, and carries two separate cams, one to each cylinder. Each cam actuates the rods, which open the corresponding exhaust valve of the cylinder to which it belongs. Access to the chamber can be obtained by removing the cover, which is bolted on by lugs *b*, *b*. The arrangements for producing the spark differ somewhat from those in a single cylinder engine. The commutator is shown in fig. 8. A is the half speed shaft, carrying a cam plate B, provided with two projections C and D, and two recesses E and F. The cams engage the two ends of a rocker G, which carries a spring H, on which are platinum contact pieces at K. In the position shown the cam C is in action, displacing the spring or trembler H till it makes contact with the insulated terminal L. After a quarter of a revolution, C will have moved into the position now occupied by D, and

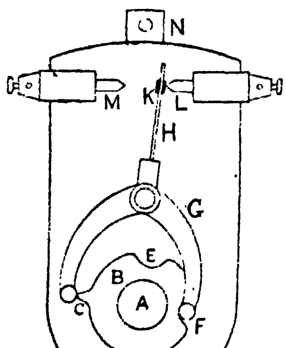

Fig. 8.—Contact Breaker of Two-Cylinder Engine.

the latter will have engaged the other arm of the rocker at F, bringing the spring H into contact with the terminal M. Two coils are used, one end of the primary of each being connected to each of the terminals M and L, and the secondaries to the sparking plugs of the respective cylinders. The spark is timed by turning the contact breaker by means of a lever attached to the lug N, as in the case of the one cylinder engine previously described.

Petrol engines are also constructed to work with a Two Stroke Cycle. They are somewhat less efficient than the four stroke type, but may be made of simpler construction, and also to run slower; they are suitable for small launches and motor boats, in which they are connected directly to the propeller shaft without any intermediate gearing. Their mode of action may best be followed by commencing with the working stroke. The charge of gas is fired by a spark and the piston is driven forward; as it nears the end of the stroke it uncovers a port or opening in the side of the cylinder, which opens directly into the exhaust pipe, and the products of combustion commence to escape. The piston after advancing still further uncovers a second port, which communicates with a space containing the explosive gas, which has already been slightly compressed (*vide infra*), and therefore commences to flow into the cylinder. A projecting plate, or **Deflector**, on the piston deflects this stream of gas towards the top of the cylinder, thereby preventing it from escaping by the exhaust port, and further helping to sweep the burnt gas out of the cylinder. At the instant the working stroke ends, the cylinder is thus mainly filled by the fresh mixture; during the return stroke compression commences immediately the piston has passed the two open ports, and is completed at the end of the stroke, when ignition again occurs, and a fresh working stroke begins. As there is an explosion every revolution, the contact breaker can be

fixed on the main shaft, and no gear wheels and half speed shaft are required. The preliminary compression of the charge requires special arrangements; in some two stroke engines this is effected by a pump driven by the engine and communicating directly with the admission port. In another type the compression is produced in the crank chamber. During the up or return stroke of the piston the charge is drawn into the crank chamber through an admission valve which closes immediately the down or working stroke commences, and the piston itself compresses the charge; when the piston has passed the admission port the gas enters the latter through a tube or channel leading from the crank chamber. The only valve in this type of engine is the one by which the mixture enters the crank chamber, and that valve is of the simplest construction and automatic in action. If the purity of the mixture could be maintained and loss of unburnt gas through the exhaust port prevented, a two stroke engine should give approximately double the power (per stroke) of a four stroke engine of the same dimensions; but in practice these conditions are never fulfilled, and the power is little, if any, greater than that of a four stroke engine of the same size.

Petroleum Engines. *See* OIL ENGINES.

Petroleum, Mineral, *or* Rock Oil. An oily liquid found in the earth in many different parts of the world. From it are made several important and useful commodities, such as the well known illuminating oil, gasoline, naphtha, benzoline, and other oils which are more or less volatile; lubricating oils, vaseline, and paraffin wax. The supply of petroleum to England is almost wholly confined to the United States and Russia. A little crude oil is imported, and is refined in the neighbourhood of Chester, but nearly all of the petroleum products are received ready for use.

The origin of petroleum has been the subject of much speculation among scientific men, and various hypotheses have been advanced to account for it. The hypothesis which has obtained general acceptance is that petroleum is wholly derived from organic matter, often from a mixed animal and vegetable origin with a considerable preponderance of the former in the case of European petroleums and of the latter in that class of which Pennsylvania petroleum is a type. The oil as it comes from the earth varies in colour from a pale oil to a thick black substance, and in density from about 0·500 to 0·975. The chemical composition also varies largely, and is usually quite complex, comprising the series of hydrocarbons known respectively as the paraffin and the olefine series. In some examples nearly the whole series has been found to be present, while in others the olefines may be entirely missing. The quantity of carbon and hydrogen varies from 87·0 and 12·0 respectively, in the case of oil found in Java, to an average of 84·0 of carbon and 14·0 of hydrogen in Pennsylvanian oil. The method of obtaining the oil varies, but often consists of sinking wells which sometimes are 1,200 to 1,500 ft. deep. Usually the sides of the wells are lined, in order to prevent water percolating through, but this is not always necessary. In some cases, as soon as a well is sunk to a certain level, there is a great gush of oil, which may last for some days; but as a rule pumps are required to bring the oil to the surface. It is then conducted to storage tanks, and in a few cases put into barrels for conveyance to the refinery, but more often it is forced through pipe lines to central stations, where it is refined. These pipe lines are in some cases 6 in. in diameter, and as much as three hundred miles in length. A series of pumping engines are stationed along the line, about four being required in every hundred miles.

The refining of petroleum consists of a system of fractional distillation. The crude oil is introduced into a still of simple form connected with a condenser, an apparatus consisting of an elaborated coil upon which sprays of cold water descend. Fires being lighted under the still, the lighter vapours are first driven off, and are condensed in the coil or condenser. The first oil so obtained is crude naphtha, which is afterwards subjected to further distillation for the production of gasoline, benzene, and refined naphtha. The second product of the distillation of the crude petroleum is the source of the different burning oils. These are afterwards refined by agitating with sulphuric acid and caustic soda or ammonia solutions, the impurities uniting with the acid to form a tar, which is afterwards run off.

A third series of heavy oils are obtained from the still, and these are principally used for lubricating purposes after the wax has been withdrawn. The process of obtaining the different varieties of oil, although spoken of here as resulting in three separate classes, may be further divided up or arranged to produce directly a much greater number of oils according to the properties of the crude oil under treatment.

In the production of paraffin oils (*q.v.*) the process is essentially the same, excepting that the supply of crude oil, instead of being obtained from wells, is derived from bituminous shale by burning it in suitable retorts. In either case the distillation of the crude oil is proceeded with until there is nothing left but a little refuse in the shape of coke, and even this is of service for making fires on yachts and for domestic purposes, as it burns very brightly and gives off no smoke whatever. In some cases the coils used for condensing the vapours consist of a vertical network of coils of pipes through which the vapours pass, and are cooled in their progress simply by the action of the atmosphere. In others a shower or spray, produced by passing water from a tank through perforated plates so as to discharge over the coil, is used. Another form of condenser employed in the Scotch oil refineries consists of a long series of coils partly immersed in water. At various points upright water pipes are provided, at the end of which are pivoted crosspieces perforated with small holes. The holes on one arm of the crosspiece look the opposite way to those on the other, so that the force of the water causes these crosspieces to revolve, thus discharging the water upon the coils in the familiar manner of a revolving lawn sprinkler. The effect is to condense the vapours much quicker than by the atmosphere.

The heavier petroleum oils contain a considerable amount of paraffin wax, which is extracted by means of a refrigerating apparatus, in which brine is cooled by means of ammonia to about 10° F. below freezing point. The oil is first passed through D-shaped atmospheric coolers fitted with stirrers which assist the process by constantly presenting a fresh surface to the cold air. The oil is then brought into contact with the cold brine, when the wax solidifies. It is then passed through filter presses and subjected to a pressure of about two tons to the square inch. This squeezes out most of the oil, and leaves behind in the presses the crude wax, which in this condition is called "PARAFFIN SCALE." In Scotland considerable

quantities of this scale are refined, including that which is derived from the shale oil and that which is imported from America. The first process of refining the scale is to melt it in a tank heated by steam, and then to run it into shallow metal trays, where it is allowed to cool. The trays are then taken to the "sweating room," where the wax is placed on strips of hemp cloth, cocoanut matting, or other open fabric, supported in trays which are slightly inclined, and are fitted with channels so that the oil which is sweated out of the wax can run away. The heat varies from 80° to 100° F., and in from eight to twenty-four hours the process is complete. The melting point and absence of colour determine to a great extent the quality of paraffin wax, and the various grades are obtained by "sweating" at different temperatures. The oil which exudes from the wax is usually passed through a filter press, when it yields a further supply of scale, which in turn yields wax of a lower melting point. Paraffin wax is largely used by candle manufacturers, by taper makers, for making imitation parchment paper, and as an insulating agent in electrical work. Vaseline is another petroleum product, and is of great use in medicine. *See* VASELINE.

LIQUID FUEL, which is gradually coming into extensive use on steamships, locomotives, and stationary engines, consists of the residue of petroleum after the lighter and burning oils have been withdrawn by distillation. Most of the petroleum lubricating oils (*see* LUBRICANTS) are mixed with various other oils, animal or vegetable, or both. Thus an oil suitable for lubricating dynamos may be made by mixing cocoanut oil with mineral oil of specific gravity ·908 and ·885. PETROL employed in motors is a mixture of various light petroleum distillates, and should have a specific gravity of about ·7. Volatility and homogeneity of boiling points are, however, the most reliable tests of the quality of petrol.

Nearly every country has very stringent laws regulating the storage and sale of the lighter petroleum oils. In England oils giving off an inflammable vapour at over 73° F. when tested by the Abel close test apparatus are practically free from restrictions; but in most other countries the flashing point (*q.v.*) is higher, commonly 100° F. Various attempts have been made to amend the English law in this respect, but a section of the oil trade have thus far successfully opposed the proposal. The paraffin oil trade—a term generally used in connection with the Scotch shale oil industry—have always produced illuminating oils of high flashing point.—A. S. J.

Petrology *or* **Petralogy** (*Geol.*) The branch of geological science which is concerned with the study of rocks. Strictly speaking, the word denotes the study of the larger features of rocks as they occur in the field, without regard to their intimate structure as revealed in the laboratory by means of the microscopic examination of thin sections of the rocks under polarised light or by other means. This latter study, which has now attained to great importance, was originally, and should still be termed, Lithology.

Peu (*Music*). A little.

Phaleræ (*Archæol.*) Bosses or discs, generally of precious metal, worn by the Greeks and Romans upon helmets, and sometimes on breastplates. Phaleræ were also attached to the harness of horses, and were worn by Roman slaves.

Pharynx (*Zool.*) The cavity at the back of the mouth leading to the ŒSOPHAGUS, and also to the GLOTTIS or opening of the windpipe.

Phase (*Phys.*) If a particle be describing a Simple Harmonic Motion, and the displacement be defined by the equation $x = r \sin \theta$, then the angle θ (which is equal to ωt) is termed the PHASE. The angle θ may be measured from any fixed radius of the Circle of Reference. *See* SIMPLE HARMONIC MOTION.

Phaseolus (*Botany*). A genus of *Leguminosæ*, including the various species of beans.

Phase Rule (*Chem.*) (1) PHASE: Let some salt and water be placed in a stoppered bottle, and let there be more salt than the water can dissolve, and let the amount of salt and water be insufficient to fill the bottle. Then, the bottle being closed, we shall have present in it a homogeneous solid—the undissolved salt; a homogeneous liquid—the saturated solution of salt; and a homogeneous gas—vapour of water and some air. Each of these is called a phase. Suppose now sugar and ether are added to the contents of the bottle, the sugar being more in amount than can be dissolved by the water, and that the bottle is still not full. Then there are two solid phases—salt and sugar; two liquid phases—an aqueous solution of salt and sugar and a layer of ether; one gaseous phase containing air, water vapour, and ether vapour. Thus in any system every homogeneous solid in the system is a phase, so also is every homogeneous liquid, while there can only be one gas phase. (2) COMPONENTS: Every independently variable substance in a system is a component. Suppose the bottle to contain only salt, water, and water vapour, then there are two components. Again, imagine a sealed flask containing solid ammonium chloride and exhausted of air. Let it be heated to such a temperature that a part of the ammonium chloride vaporises and forms ammonia and hydrochloric acid gas. In this case there is only one component, viz. ($NH_3 + HCl$); for the ammonia cannot be present except there is an equivalent of the acid gas, and the composition of the gas phase is identical with that of the solid phase. But if ammonia gas were introduced into the system, then it would become a system of two components. (3) DEGREES OF FREEDOM: The *only* conditions which can effect a change of the equilibrium in a system according to the phase rule are temperature, pressure, concentration of components. The number of these remaining to be fixed before the state of the system considered becomes fixed and determinate is called the degrees of freedom of the system. Let P, C, and F denote respectively the number of phases, components, and degrees of freedom in any system which is *in equilibrium*, then the phase rule is

$$P + F = C + 2.$$

From this it is clear that in a system in equilibrium of one component there can never be more than two degrees of freedom nor more than three phases. Example: If ice, water, and water vapour exist together in equilibrium, the system has no degrees of freedom (invariant system), and any change of temperature, pressure, or concentration would mean that at least one phase must disappear. Suppose there are two components; then four phases can exist in equilibrium, but in this case the system is invariant: three phases could exist together with one degree of freedom (univariant system), etc. Example: Let the two components be sodium sulphate and water; then four phases which could exist together in equilibrium would be anhydrous sodium sulphate, Glauber's salt ($Na_2SO_4 10H_2O$), a solution of sodium sulphate of a particular concentra-

tion, water vapour at a definite and fixed pressure —say p.mm. Let the vapour pressure be reduced to p′.mm. and remain constant at this; then the system will change until a new equilibrium is set up, and the change will be very complex—the solution must become more concentrated, and this would involve the solid phases, one at least of which would disappear—while thermal changes also must occur. The state of a system is conveniently represented by diagrams. The above two component systems can be represented by two diagrams.

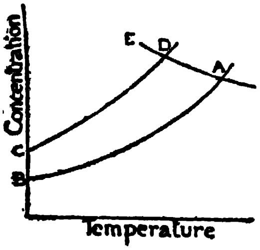

Diagram 1.

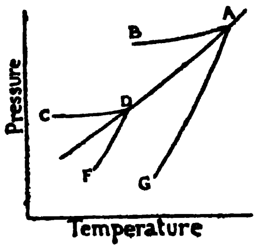

Diagram 2.

The first of these represents the solubilities of Na_2SO_4 (E D A), of $Na_2SO_47H_2O$ (C D), of $Na_2SO_410H_2O$ (A B). The second represents the vapour pressures of the solution of Na_2SO_4 (A D), of the solution of $Na_2SO_410H_2O$ (A B), of the solid $Na_2SO_410H_2O$ (A G), of the solution of $Na_2SO_47H_2O$ (C D), of the solid $Na_2SO_47H_2O$ (D F). The equilibrium of the four phases referred to above is indicated by the point A (quadruple point) in the two diagrams. It is clear there is another quadruple point D, where the four phases—solid Na_2SO_4, solid $Na_2SO_47H_2O$, solid of Na_2SO_4 of a particular concentration, water vapour at a particular pressure denoted by the point D in Diagram II.—can exist in equilibrium. The phase rule is of great service in studying the various hydrates of salts and the formation of salt deposits, such as those at Stassfurt, and in studying alloys such as the copper tin alloys and the carbon iron alloys. It will be noticed that the phase rule does not distinguish between physical and chemical changes, and that it takes no account of the mass of any phase; but the mass must not be so small that surface tension effects interfere with the changes.

Phases of the Moon (*Astron.*) Apparent changes in form of the illuminated portion of the moon turned towards the Earth, due to the moon's motion round the Earth.

Phase Splitter (*Elect. Eng.*) A device for producing a difference of phase between two alternating currents which were originally in the same phase, or which were derived from a single alternating current. A phase splitting device is often used in starting a single phase alternating current motor.

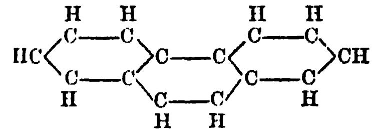
Phellogen (*Botany*). *See* CAMBIUM.

Phenacetin (*Chem.*) Paracetamidophenetole, $CH_3CONHC_6H_4OC_2H_5$. A white crystalline (scales) solid; melts at 135°; very sparingly soluble in water; soluble in alcohol and glycerine. It is used in medicine to relieve pain. Strong sulphuric acid converts it into ethyl acetate and paramidophenol,

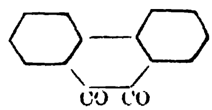
$$CH_3CONHC_6H_4OC_2H_5 + H_2O = CH_3COOC_2H_5 + H_2N \cdot C_6H_4OH.$$

It is prepared from paranitrophenol; the potassium salt of the latter, on boiling with alcohol and potassium ethyl sulphate, gives paranitrophenetole, which on reduction gives paramidophenetole; and this compound when boiled with glacial acetic acid gives phenacetin.

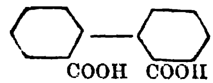
Phenanthrene.



A white crystalline solid (plates); melts at 99°; slightly soluble in water; easily soluble in ether, benzene, and hot alcohol; its solutions have faint blue fluorescence. Forms a picrate which melts at 140°. Forms substitution products with chlorine, nitro-derivatives with nitric acid, and sulphonic acids with sulphuric acid. On oxidation with chromic acid it gives phenanthraquinone,



a yellow crystalline (needles) solid, which melts at 198°. This compound on further oxidation gives diphenic acid,



and diphenic acid when heated with soda-lime gives diphenyl, $C_6H_5 - C_6H_5$. These reactions show that phenanthrene is a diphenyl derivative, and as phenanthrene can be obtained by passing dibenzyl or stilbene through a red-hot tube, its constitution must be represented as above.

$$\begin{array}{c} C_6H_5 \cdot CH_2 \\ | \\ C_6H_5 \cdot CH_2 \end{array} \rightarrow \begin{array}{c} C_6H_4 \cdot CH \\ | \quad\quad \| \\ C_6H_4 \cdot CH \end{array} \leftarrow \begin{array}{c} C_6H_5 \cdot CH \\ \| \\ C_6H_5 \cdot CH \end{array}$$

It occurs in crude anthracene, from which it can be separated by carbon disulphide—in which it is more soluble than anthracene—and purified by conversion into the picrate. Morphine is a phenanthrene derivative.

Phenetole (*Chem.*) $C_6H_5OC_2H_5$. The ethyl ether of phenol. It is a colourless oil which boils at 172°. It may be obtained by the action of ethyl iodide on potassium phenate.

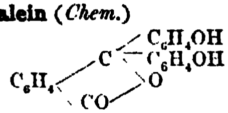
Phenol (*Chem.*) C_6H_5OH, Carbolic acid. Forms colourless prisms; melts at 42°; boils at 183°; is volatile in steam; has a characteristic smell; blisters the skin; is very poisonous; largely used as a disinfectant. Soluble in water (1 part in 14 parts water); more soluble in the usual organic solvents, alcohol, ether, benzene, etc. It is deliquescent. When exposed to air and light it turns red. Chlorine and bromine yield symmetrical trichlor- and tribrom-phenol, $C_6H_2Br_3OH$; in presence of a halogen carrier chlorine will yield higher chlorinated products, while in alkaline solution it breaks the benzene ring. Sulphuric acid probably forms phenyl sulphuric acid, $SO_2\langle^{OC_6H_5}_{OH}$; but this undergoes rearrangement to ortho- and para-phenol sulphonic

acids, $HOC_6H_4SO_2OH$. Salts of phenyl sulphuric acid are known, and potassium phenyl sulphate, $SO_2\langle^{OC_6H_5}_{OK}$, occurs in urine. Nitric acid gives a mixture of ortho- and para-nitrophenol; stronger acid gives picric acid (*q.v.*) The phenyl group confers slight acid properties on the hydroxyl hydrogen atom, so that phenol unites with powerful bases to form salts: *e.g.* with caustic soda and caustic potash it forms sodium and potassium phenates, C_6H_5ONa and C_6H_5OK; but it will not react with a carbonate. Like an alcohol, phenol forms ethers with other alcohols; *e.g.* potassium phenate and methyl iodide give phenylmethyl ether (anisole), $C_6H_5OCH_3$ (*see also* PHENETOLE); with acids (better, acid-chlorides) it forms esters, *e.g.*:

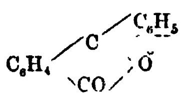
$$C_6H_5OH + ClOC.CH_3 = \underset{\text{Phenyl Acetate.}}{CH_3COOC_6H_5} + HCl$$

Ferric chloride imparts a violet colour to its solution. Concentrated sulphuric acid, followed by a solution of a nitrite, gives a deep red colour with phenol, which turns blue with alkali (Liebermann's Reaction). For other reactions relating to phenol, *see* SALICYLIC ACID, PICRIC ACID, NITRO COMPOUNDS, NITROSO COMPOUNDS. The chief source of phenol is coal tar. *See* GAS MANUFACTURE, p. 248. It can be obtained from benzene-sulphonic acid by fusion with caustic potash; also by boiling diazobenzene sulphate (*see* DIAZO REACTIONS) with water.

Phenolphthalein (*Chem.*)



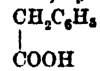
Small yellowish white crystals; melts at 250°; insoluble in water; soluble in alcohol. It is prepared by heating together 5 parts phthalic anhydride, 10 parts phenol, and 4 parts concentrated sulphuric acid for several hours at 115 to 120°. The product is extracted by boiling with water, the insoluble part dissolved in caustic soda solution, and the phenolphthalein precipitated from this solution by neutralisation with acetic acid and a little hydrochloric acid. That it has the above constitution is shown by its preparation from phthalophenone,



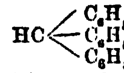
by successive nitration, reduction, and diazotisation. *See* PHTHALEINS. Phenolphthalein is a valuable indicator (*q.v.*); it is specially useful in the titration of weak acids by strong alkalis; it should not be used with weak bases. Excess of a strong alkali decolorises it. For its use as an indicator and the theory of its action, *see* INDICATORS.

Phenols (*Chem.*) A class of compounds derived from benzene or from homologues of benzene by replacing one or more hydrogen atoms of the benzene nucleus by hydroxyl groups. For examples *see* PHENOL, PICRIC ACID, THYMOL, CRESOLS, CATECHOL, HYDROQUINONE, RESORCIN, PYROGALLOL, PHLOROGLUCIN.

Phenyl (*Chem.*) The name given to the group C_6H_5, derived from benzene by removal of any one atom of hydrogen. The group has no independent existence. The word is much used in naming benzene derivatives, *e.g.*



Phenylacetic Acid.

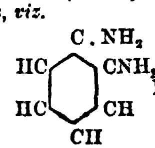


Triphenylmethane.

Phenylene (*Chem.*) A name given to the group C_6H_4, which is derived from benzene by the removal of any two of its hydrogen atoms. When the two hydrogen atoms removed are adjacent, the residue is called orthophenylene; when next but one to each other, metaphenylene; when opposite, paraphenylene. The group has no independent existence.

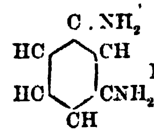
Phenylenediamines (*Chem.*) There are three of these compounds, *viz.*

Orthophenylene-diamine



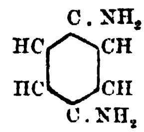
M.P. 102°. B.P. 252°.

Metaphenylene-diamine



M.P. 63°. B.P. 287°

Paraphenylene-diamine

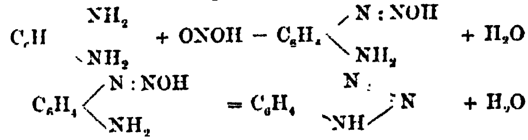


M.P. 147° B.P. 267°.

They are all white crystalline (plates) solids; soluble in water; more soluble in alcohol and ether. They are diacid bases. *The ortho-compound* Benzanilide is nitrated, the product saponified and distilled in steam, when orthonitraniline distils over; this is reduced by caustic soda and zinc dust.

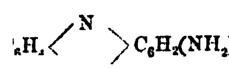
$$C_6H_5NHCOC_6H_5 \rightarrow C_6H_4NO_2NHCOC_6H_5 \rightarrow C_6H_4NO_2NH_2 \rightarrow C_6H_4(NH_2)_2$$

The orthonitraniline can also be prepared by heating orthonitrophenol with ammonia under pressure. With nitrous acid it gives azimidobenzene:



Azimidobenzene.

On oxidation it gives unsymmetrical diaminophen-



The meta-compound is obtained by reduction of metadinitrobenzene with tin and hydrochloric acid. *See* NITROBENZENE. With nitrous acid it yields Bismarck Brown (*q.v.*) *The para-compound* is obtained by nitrating acetanilide in presence of much sulphuric acid at a low temperature; the paranitracetanilide is hydrolysed, and the resulting paranitraniline reduced by tin and hydrochloric acid. It is also obtained by heating phenylhydrazine with hydrochloric acid at 200°. For its reaction with ferric chloride and sulphuretted hydrogen *see* LAUTH'S VIOLET. It is

oxidised by manganese dioxide and sulphuric acid to quinone. A hypochlorite gives quinone dichlorimide, $ClN:C_6H_4:NCl$. Its dimethyl derivative (paradimethylphenylenediamine) is used in the preparation of methylene blue (*q.v.*), and is prepared by reducing nitrosodimethyl aniline. *See* NITROSO COMPOUNDS, INDAMINES, SAFFRANINE.

Phenylhydrazine (*Chem.*) $\genfrac{}{}{0pt}{}{C_6H_5}{H}{>}N.NH_2$

Colourless prisms or plates; melts at 23°; boils at 246°, with decomposition; peculiar smell; sparingly soluble in water; easily soluble in alcohol, ether, etc. It is a base, forming well crystallised salts, *e.g.* phenylhydrazine hydrochloride, $C_6H_5NH:NH_2HCl$. It reduces Fehling's solution. Zinc dust and hydrochloric acid reduce it to aniline and ammonia. Boiled with copper sulphate or ferric chloride, it yields benzene. With aldehydes and ketones it yields hydrazones (*q.v.*) With sugar it yields osazones (*q.v.*) For its reaction with acetoacetic ester, *see under* ETHYLACETOACETATE. It is very important as a reagent for aldehydes, ketones, and sugars; also in the preparation of antipyrine (*q.v.*) It is prepared by diazotising aniline with hydrochloric acid and sodium nitrite (*see* DIAZO REACTIONS), and reducing the diazobenzene chloride with tin and hydrochloric acid; this gives phenylhydrazine hydrochloride, which is filtered off, dissolved in water, decomposed by potash, and extracted with ether. The ether is distilled off, and the base fractionally distilled under reduced pressure.

Phenylisocyanate (*Chem.*) $C_6H_5N:CO$, Carbanil. A colourless liquid; boils at 166°; penetrating smell. It reacts with compounds containing hydroxyl and amino groups to form substituted ureas, *e.g.*

$$2C_6H_5N:CO + HOH = (C_6H_5.H.N)_2CO + CO_2$$

$$C_6H_5N:CO + NH_3 = \begin{matrix} C_6H_5.HN \diagdown \\ \quad CO. \\ H_2N \diagup \end{matrix}$$

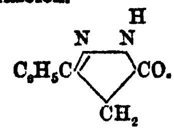
Hence it is used in determining the presence of these groups in compounds, and also sometimes in isolating such compounds from mixtures. It is prepared by acting on diazobenzene chloride (*see* DIAZO REACTIONS) with potassium cyanate and finely divided copper; also by heating phenyl mustard oil (*see* MUSTARD OILS) with mercuric oxide.

Phenylisocyanide (*Chem.*) C_6H_5NC, Phenylcarbylamine. A colourless liquid; boils at 166° and polymerises; boils unchanged under reduced pressure; powerful and offensive smell, which causes sickness; on keeping it turns blue in colour and resinises. On heating at 220° it undergoes rearrangement to phenyl cyanide, C_6H_5CN; on reduction it yields methyl aniline. It is obtained by heating aniline with chloroform and alcoholic potash.

$$C_6H_5N\begin{matrix}\diagup H \\ \\ \diagdown H\end{matrix} + \begin{matrix}Cl\diagdown \\ \\ Cl\diagup\end{matrix}C\begin{matrix}\diagup Cl \\ \\ \diagdown H\end{matrix} + 3KOH = C_6H_5NC + 3KCl + 3H_2O.$$

This reaction is used as a test for chloroform or aniline, as the smell of the isocyanide is unmistakable.

Phenylpropiolic Acid (*Chem.*) $C_6H_5C:C.COOH$. A white crystalline solid; melts at 136°; heated to 120° with water it gives phenylacetylene, $C_6H_5C:CH$, and carbon dioxide; on reduction with sodium and alcohol it gives cinnamic acid; with hydrazines it forms pyrazole derivatives, *e.g.* hydrazine hydrate gives 3-phenylpyrazolon.



It is obtained from dibromcinnamic acid (*see* CINNAMIC ACID) by boiling with alcoholic potash. The ortho-nitro phenylpropiolic acid is similarly obtained from orthonitrocinnamic acid dibromide; alkaline reducing agents, *e.g.* grape sugar and caustic potash, convert it into indigo.

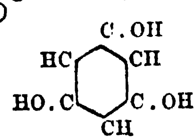
Pheon (*Her.*) The barbed iron head of spear or arrow, engrailed on the inner side, generally with point downwards.

Phigaleian Marbles (*Sculp.*) The name given to the sculptured frieze of the cella of the Temple of Apollo at Phigalia, in Arcadia. It was brought to this country early in the nineteenth century, and is now in the British Museum. Represents contests between the Centaurs and Lapithæ. *See* ELGIN MARBLES.

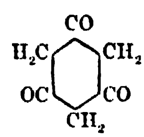
Phlexine. *See* DYES AND DYEING.

Phloridzin (*Chem.*), $C_{21}H_{24}O_{10}$. White crystalline solid (needles); melts at 108°; sparingly soluble in cold water, easily soluble in hot water and in alcohol. Lævorotatory. Hydrolysed by acids to glucose and phloretin. The latter is the phloroglucinol ester of paraoxyphenylpropionic acid. $HOC_6H_4CH_2.CH_2.COOH$. When phloridzin is administered it gives rise to a condition known as phloridzin diabetes. In this condition far more glucose is excreted in the urine than can be accounted for by the hydrolysis of the phloridzin: and phloretin itself, which contains no glucose residue, can produce phloridzin diabetes. It is supposed therefore that the glucose arises from protoplasmic metabolism. Phloridzin occurs in the root bark of a number of common fruit trees, such as the apple, cherry, pear, and plum; it can be extracted from these barks by dilute alcohol.

Phloroglucinol (*Chem.*) (1 : 3 : 5-trihydroxybenzene)



tautomeric form :—



(1 : 3 : 5-triketohexamethylene).

Crystallises in colourless prisms with two molecules of water; loses its water at 100° and melts at 218°; soluble in water, alcohol, and ether; sweet taste. Its aqueous solution is coloured violet by ferric chloride, and is resolved by passing in chlorine into dichloracetic acid and tetrachloracetone. Its alkaline solution absorbs oxygen and reduces Fehling's solution. Phloroglucinol yields a triacetate with acetyl chloride. With hydroxylamine it reacts in the tautomeric form and yields a trioxime. In the form of Gunsberg's reagent it is used as a test for free hydrochloric acid in the gastric juice. When the reagent (2 parts phloroglucinol, 1 part vanillin, 30 parts

rectified spirit) is warmed with the liquid to be tested, it gives a red colour—sensitive to 1 part acid in 10,000. It is also used, mixed with hydrochloric acid, as a test for pentoses, with which it gives a red colour with a characteristic absorption band. It is formed when quercetin, gamboge, dragon's blood, and other resins are fused with caustic potash. To prepare it, resorcin (*q.v.*) is fused with caustic soda, or symmetrical trinitrobenzene is reduced by tin and hydrochloric acid, and the resulting double salt of triamidobenzene and tin hydrochlorides hydrolysed by caustic soda. It is also obtained by fusing ethylphloroglucin tricarboxylate with caustic potash. *See* MALONIC ACID.

Phobos (*Astron.*) The inner satellite of Mars.

Phone. A colloquial contraction for Telephone.

Phonograph. A machine for recording and reproducing definite sounds. To produce a RECORD, the voice or sound to be recorded is made to set in vibration a light diaphragm, carrying a sharp tracing point or style, which makes contact with a cylinder coated with wax. This cylinder is caused to revolve, and the recorder to slowly travel from one end of the cylinder to the other. As it does so the movement of the style cuts a groove, whose depth corresponds to the vibrations of the diaphragm. If the sharp point be replaced by a smooth ended needle, which is allowed to rest in the groove, the motion of the cylinder will cause the style, and therefore the diaphragm, to reproduce its original vibrations, and thereby reproduce the sounds which caused these vibrations with more or less fidelity. The instrument is frequently sold under the name GRAPHOPHONE, and large numbers of records of all kinds can be obtained. In the GRAMAPHONE the records are formed on a flat rotating disc, but the essential principle remains unaltered except that records cannot be made by the user.

Phonolite (*Geol.*) In its original sense it meant any rock of eruptive origin which clinked or gave forth a kind of metallic ring when struck with a hammer. At the present day the term is restricted to an eruptive rock (generally, if not always, of trappean mode of occurrence, *i.e.* intrusive), which consists of a lithoidal ground mass agreeing in mineral constitution with Syenites and Trachytes (*q.v.*), but which contains the mineral Nepheline.

Phormium (*Botany*). The generic name for New Zealand flax.

Phorone (*Chem.*)

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!>\!C:CH-CO\cdot\cdot CH:C\!<\!\begin{matrix}CH_3\\CH_3\end{matrix}$$

Yellow prisms (it contains the group $-\underset{\|}{C}-\overset{O}{\overset{\|}{C}}-\underset{\|}{C}-$ like quinone); melts at 28°; boils at 197°; smells like geranium; soluble in alcohol and benzene. Boiled with dilute sulphuric acid it yields mesityl oxide and acetone; heated with strong sulphuric acid, mesitylene. Like a ketone, it unites with sodium hydrogen sulphite, forms an oxime, and unites with hydrocyanic acid (KCN solution and HCl). It is obtained, along with mesityl oxide (*q.v.*), by the action of hydrochloric acid on acetone, and is separated by fractional distillation from the mesityl oxide, which only boils at 132°.

Phosgene Gas (*Chem.*) An old name for CARBONYL CHLORIDE (*q.v.*)

Phosgenite (*Min.*) A chloride and carbonate of lead, $PbCl_2 . PbCO_3$. White or grey, sectile; from Cromford in Derbyshire, Elgin, Cornwall, etc. *Also called* CROMFORDITE.

Phosphate of Iron (*Min.*) *See* VIVIANITE.

Phosphate of Lead (*Min.*) *See* PYROMORPHITE.

Phosphate of Lime (*Min.*) *See* APATITE.

Phosphates (*Chem.*) Salts of orthophosphoric acid, H_3PO_4. *See* under PHOSPHORUS COMPOUNDS. The individual phosphates, when they are of importance, are described under the corresponding metal. *See* SODIUM COMPOUNDS, CALCIUM COMPOUNDS, MAGNESIUM COMPOUNDS.

Phosphatic Nodules (*Geol.*) These are often, but erroneously, spoken of under the name of COPROLITE. They consist essentially of calcareous matter, containing a sufficiently high percentage of phosphoric acid to be of commercial value in the manufacture of artificial manures. The phosphoric acid seems to be, in nearly all cases, of organic origin; but the precise mode of formation of the nodules is not yet well understood. Important deposits of phosphate of lime arise from the prolonged action of guano upon limestone islands in the rainless regions of the Pacific. Others may be due to the decomposition on the ocean floor of large numbers of fish which have been killed by a sudden change of temperature of the sea water in which they lived.

Phosphides (*Chem.*) Compounds formed by the union of phosphorus and one other element, *e.g.* calcium phosphide. *See* CALCIUM COMPOUNDS *and* HOLMES'S SIGNAL.

Phosphine (*Chem.*) A name for phosphoretted hydrogen. *See under* PHOSPHORUS COMPOUNDS.

Phosphines (*Chem.*) Compounds derived from phosphine (phosphoretted hydrogen) by replacing the hydrogen by alcohol radicals, *e.g.* $P(C_2H_5)_3$ is triethyl phosphine, $PH_2C_2H_5$ is ethyl phosphine.

Phosphomolybdic Acid (*Chem.*) *See* MOLYBDENUM AND ITS COMPOUNDS.

Phosphonium Compounds (*Chem.*) The name phosphonium is given to the group PH_4, from analogy with the group NH_4, which is called ammonium. PHOSPHONIUM CHLORIDE, PH_4Cl, does not exist under the ordinary conditions of temperature and pressure. It is formed by the union of phosphoretted hydrogen and hydrogen chloride either at −25° or under a pressure of 20 atmospheres at the ordinary temperature. PHOSPHONIUM BROMIDE, PH_4Br, is a white crystalline solid which dissociates into phosphoretted hydrogen and hydrogen bromide at its melting point, *viz.* 30°; it is decomposed by water into the same substances, and it is formed from them by direct union at the ordinary temperature. PHOSPHONIUM IODIDE, PH_4I, is a shining crystalline solid; easily sublimes on warming; boils at 80°, and dissociates into phosphoretted hydrogen and hydriodic acid; decomposed by water into the same substances; warmed with caustic potash it gives phosphoretted hydrogen. *See* PHOSPHORUS COMPOUNDS. It is formed by dissolving phosphorus and iodine in carbon disulphide in a retort, evaporating the solvent in a stream of carbon dioxide, and gently heating the residue, with gradual addition of water. The phosphonium iodide sublimes. The carbon dioxide is to exclude air, and materials and apparatus must be dry. Phosphonium iodide is used in

the preparation of organic derivatives of phosphorus, such as triethylphosphine $P(C_2H_5)_3$. *See* PHOSPHORUS COMPOUNDS.

Phosphor Bronze (*Met.*) Bronze containing 2 to 5 per cent. of phosphorus. It is very hard and durable, and suitable for parts of machinery exposed to shocks. As its electrical conductivity is good, it is employed for telephone wires, etc., being much stronger than pure copper.

Phosphorescence (*Phys.*) Certain substances, after exposure to light, exhibit a degree of luminosity for some time. This property is termed PHOSPHORESCENCE. The sulphides of calcium, barium, and strontium are examples.

Phosphoretted Hydrogen (*Chem.*) *See* PHOSPHORUS COMPOUNDS.

Phosphorus (*Chem.*) P. Atomic weight, 31. A colourless crystalline solid; but ordinarily it is slightly yellow and translucent; melts at 44°, and sublimes below this temperature in an atmosphere which does not act on it; boils at 290°; it has a vapour density corresponding to the formula P_4 at 1,000°, and to the formula P_2 at 1,750°. Phosphorus is insoluble in water, slightly soluble in ether and a number of oils, easily soluble in carbon disulphide. It is very poisonous, and on this account is used as a vermin killer. The "phosphorus paste" used for this purpose consists of fat mixed with a little phosphorus, and usually flour and sugar and a colour. Its vapour also is dangerous, as it attacks and destroys the jawbones of people such as matchmakers, who are constantly exposed to its action. Phosphorus unites directly with many elements. With oxygen it unites with extreme ease in presence of moisture, but not at all in the total absence of moisture. The luminosity of phosphorus seen in the dark or in a feeble light is due to a low temperature flame arising from the slow combustion of the phosphorus in moist air or oxygen; in oxygen at atmospheric pressure phosphorus is not luminous, but becomes so on reducing the pressure or on warming. The glow of phosphorus is prevented by the presence of small quantities of easily oxidisable gases and vapours. A piece of phosphorus left exposed to air will take fire spontaneously on standing; on warming, it ignites at 60°, forming chiefly the pentoxide; on this account phosphorus is kept under water. The products of this slow oxidation are phosphorous oxide, phosphoric oxide, ozone, and hydrogen peroxide; the two oxides unite with water, and give phosphorous and phosphoric acids. Phosphorus readily unites with all the halogens; iodine put upon phosphorus sets it on fire in air; phosphorus dropped into bromine instantly unites with it with a loud explosion, and it burns spontaneously in chlorine and fluorine. Placed in solutions of salts of metals with easily reducible oxides, phosphorus precipitates the metal, which in some cases unites with the phosphorus to form a phosphide, *e.g.* it precipitates silver from silver nitrate—Stas prepared pure silver in this way; it precipitates copper from copper sulphate, and the copper unites with the phosphorus to form a phosphide. For the action of alkalis and nitric acid, *see* PHOSPHORUS COMPOUNDS. Ordinary phosphorus under the influence of heat and certain catalytic agents (a trace of iodine or phosphorus tribromide) changes to the red modification. This red phosphorus consists of very small crystals, and is insoluble in those solvents which dissolve ordinary phosphorus, is not poisonous, takes fire at a much higher temperature in air, and in general reacts slowly with those elements and compounds which react rapidly with ordinary phosphorus, and has a much lower vapour pressure and higher melting point than ordinary phosphorus. As yellow phosphorus changes with extreme slowness at the ordinary temperature into the red modification, it is probable that the red form is a polymer of the ordinary form. To obtain the red form in quantity, ordinary phosphorus is heated out of air at 250° or over; at 300° the change is very rapid. Over 350°, when the vapour pressure of the red form becomes very appreciable, this form is reconverted into the yellow form. Red phosphorus is soluble in a solution of caustic potash in diluted alcohol, and hydrochloric acid reprecipitates it from this solution. Yellow phosphorus is used in tipping ordinary matches; red phosphorus is used on the rubber and not on the tip of the match in making safety matches. Phosphorus occurs naturally as phosphates. *See under* APATITE; CALCIUM COMPOUNDS; PHOSPHORITE; WAVELLITE. It also occurs in bone (*see* BONE ASH) and in nerve tissue (*see* LECITHINS). Phosphorus is obtained by heating an intimate mixture of calcium phosphate, carbon, and sand in an electric furnace with carbon electrodes, and condensing the phosphorus vapour under water in copper vessels; the yield is about 86 per cent. It can be obtained in the laboratory by heating a mixture of aluminium powder (2·5 equivs.), sodium metaphosphate (6 equivs.), and silica (2 equivs.) in a porcelain boat contained in a piece of combustion tubing, in a stream of dry hydrogen. The phosphorus is condensed in a receiver attached to the combustion tube:

$$6NaPo_3 + 10Al + 3SiO_2 = 3NaSi_2O_3 + 2Al_2O_3 + 6P.$$

Phosphorus Compounds. WITH HYDROGEN: *Phosphoretted hydrogen* or *phosphine*, PH_3; a colourless gas; melts at −134°; boils at −85°; characteristic smell (variously described as like that of putrid fish or like garlic); very poisonous; slightly soluble in water; takes fire in air on slight heating or in oxygen on sudden reduction of pressure, and forms metaphosphoric acid and water, $4PH_3 + 16O = P_4O_{10} + 6H_2O = 2H_2P_2O_6 + 4H_2O$; decomposed to phosphorus and hydrogen on heating. It has feebly basic properties, and unites directly with hydriodic acid and hydrobromic acid at the ordinary temperature and pressure, but only at −25° with hydrochloric acid. When passed into solutions of salts of many metals, the metal or a phosphide is precipitated. It is obtained by heating phosphorus with a strong solution of an alkali—

$$P_4 + 3KOH + 3H_2O = \underset{\text{Pot. Hypophosphite.}}{3KH_2PO_2} + PH_3$$

In this case the gas is mixed with hydrogen, and another hydride, P_2H_4, which makes it spontaneously inflammable. A similar impure product arises from the action of calcium phosphide on water. The pure gas is obtained by the action of a solution of caustic potash on phosphonium iodide; the gas is only pure when the action is slow. OTHER HYDRIDES: A liquid hydrogen phosphide, P_2H_4, is obtained along with the gaseous hydride PH_3, when the latter is prepared by the action of caustic potash on phosphorus or water on calcium phosphide. It is separated from the gas by passing the gas through a tube cooled to 0°. It is a colourless liquid, which boils at 57° (735 mm.); immediately catches fire in air; decomposed by light, by heating above its boiling point, and by hydrochloric acid into a *solid* hydride and phosphoretted hydrogen, $5P_2H_4 = 2P_2H + 6PH_3$. The solid hydride is yellow, catches fire in air on heating,

and is decomposed into phosphorus and hydrogen on heating out of air. WITH HALOGENS: Phosphorus unites with all the halogens directly. The trifluoride PF_3 and pentafluoride PF_5 are gases. The *trichloride* PCl_3 is a colourless liquid; boils at 76°; fumes in air owing to its decomposition by water vapour. Water decomposes it, forming phosphorous and hydrochloric acids, $PCl_3 + 3HOH = 3HCl + H_3PO_3$. It behaves in a similar manner with organic compounds which contain hydroxy groups; for this reason it is an important reagent in organic chemistry, *e.g.* $3CH_3CO.OH + PCl_3 = 3CH_3COCl + H_3PO_3$. It is obtained by passing dry chlorine over phosphorus; the product contains pentachloride, which is removed by standing for a while over phosphorus and then distilling. The *pentachloride* PCl_5 is a yellowish white solid with powerful smell; sublimes without melting at the ordinary pressure; fumes strongly in air, owing to decomposition by water vapour. On heating it dissociates, so that its vapour is a mixture of chlorine and trichloride. When water acts slowly on it, phosphorus oxychloride is formed, $PCl_5 + H_2O = POCl_3 + 2HCl$; but the oxychloride itself is easily decomposed by water, so that with much water phosphoric acid is formed, $POCl_3 + 3HOH = PO(OH)_3 + 3HCl$. With organic or inorganic compounds containing hydroxy groups it reacts in a similar way; with organic compounds containing the carbonyl group($-CO-$) the oxygen is replaced by two chlorine atoms—hence it is an important reagent for the detection of these groups. Examples:

$$SO_2\langle{}^{OH}_{OH} + PCl_5 = \underset{\text{Chlorsulphonic Acid.}}{SO_2\langle{}^{OH}_{Cl}} + POCl_3 + HCl$$

$$\underset{\text{Acetone.}}{(CH_3)_2CO} + PCl_5 = (CH_3)_2CCl_2 + POCl_3$$

It is formed by the action of chlorine on the trichloride. The *tribromide* PBr_3 resembles the trichloride, and is prepared by mixing carbon disulphide solutions of phosphorus and bromine and distilling off the solvent. The *pentabromide* PBr_5 is a yellow crystalline solid obtained by direct union of bromine with the tribromide. A *heptabromide*, PBr_7, a red crystalline solid, decomposed into bromine, phosphoric and hydrobromic acids by water, is formed by mixing the pentabromide and bromine, and heating in a sealed tube at 90°, when the heptabromide sublimes. A *di-iodide*, P_2I_4, and tri-iodide are known; but the existence of a penta-iodide is doubtful. Many *oxyhalogen compounds* are known. The *oxyfluoride* POF_3 is formed by direct union of the trifluoride and oxygen; it is a gas. The *oxychloride* $POCl_3$ is a liquid; melts at $-1.5°$; boils at 107°. It fumes in air, owing to the presence of water vapour. Water decomposes it. *See* above. It is prepared by the action of anhydrous oxalic acid on the pentachloride,

$$\begin{matrix}COOH\\ |\\ COOH\end{matrix} + PCl_5 = CO + CO_2 + 2HCl + POCl_3;$$

also by heating the pentachloride and pentoxide in a sealed tube; by the action of potassium chlorate on the trichloride; by the action of ozone on the trichloride. It is used, like the trichloride, in organic chemistry. WITH SULPHUR: The *pentasulphide* P_2S_5 a pale yellow crystalline solid; melts at 275°; boils at 518°; decomposed by water, $P_2S_5 + 8H_2O = 2H_3PO_4 + 5SH_2$. It is used in organic chemistry in the preparation of sulphur compounds. *See* DIKETONES; LÆVULINIC ACID; MERCAPTANS. It may be prepared by heating red phosphorus and sulphur together in the proper proportions and distilling the product in a stream of carbon disulphide. WITH OXYGEN AND OXYGEN AND HYDROGEN—OXIDES AND ACIDS: *Phosphorous oxide*, P_4O_6, is a white crystalline solid; melts at 22·5°; boils at 173°; its vapour density corresponds to the formula P_4O_6; soluble in ether, carbon disulphide, benzene, and chloroform; burns in air and with great brilliancy in warm oxygen to phosphoric oxide; with cold water it slowly forms phosphorous acid, and with dilute alkalis phosphites. With warm water the action is energetic, and red phosphorus, spontaneously inflammable phosphoretted hydrogen, and phosphoric acid are produced. It is formed when phosphorus burns in a restricted supply of air. *Phosphorosophosphoric oxide*, $P_4O_6.P_4O_{10}$, is a colourless, shining, crystalline solid; dissolves slowly in water with hissing sound, and forms a mixture of phosphorous and metaphosphoric acids; on heating, it sublimes without melting and without decomposition. It is obtained by heating phosphorous oxide in an exhausted tube, when phosphorus distils away first and is followed by the phosphorosophosphoric oxide. Its vapour density at 1,400° is 229. *Phosphoric oxide*, P_4O_{10}, is ordinarily a soft white powder, but can be obtained in crystals by sublimation; on heating, it sublimes without melting; its vapour density at 1000° corresponds to a formula not less than P_4O_{10}; it combines with water with great energy, forming metaphosphoric acid, $P_4O_{10} + 2H_2O = 2H_2P_2O_6$. On this account it is used as a drying and dehydrating agent; thus, when added to nitric acid it withdraws water, and nitrogen pentoxide is formed. To obtain it, phosphorus is burnt in a free supply of air or oxygen previously dried by sulphuric acid; the product contains some phosphorous oxide, which may be removed by vapourising it in a current of oxygen and passing the mixed gases over heated spongy platinum. *Hypophosphorous acid*, H_3PO_2. *See* HYPOPHOSPHOROUS ACID. *Phosphorous acid*, H_3PO_3, is a crystalline solid; melts at 74°; it is very deliquescent. When heated it gives phosphoretted hydrogen and phosphoric acid, $4H_3PO_3 = 3H_3PO_4 + PH_3$. It is a powerful reducing agent; its solution absorbs oxygen from the air, and reduces salts of gold, silver, mercury, and copper to the metallic state. With phosphorus pentachloride it gives phosphorus trichloride, $H_3PO_3 + PCl_5 = PCl_3 + 3POCl_3 + 3HCl$. It is a tribasic acid, but the third hydrogen atom is difficultly replaced by metals. Its salts, the phosphites, are not important. The acid is obtained by the action of cold water on phosphorous oxide; by the action of the trichloride on water; or by heating the trichloride with crystallised oxalic acid. *Phosphorosophosphoric acid* (Hypophosphoric acid), $H_4P_2O_6$, is a white crystalline solid; melts at 55°; decomposes on heating into phosphoric acid and phosphoretted hydrogen; it is a weak reducing agent; it is tetrabasic. The acid is formed, along with phosphorous and phosphoric acids, when phosphorus is exposed to the action of moist air. When the liquid which results from this prolonged exposure is partly neutralised by caustic soda, the sparingly soluble sodium salt, $Na_2H_2P_2O_6$, crystallises out. A solution of this salt is decomposed by lead acetate, and the precipitated lead salt decomposed by sulphuretted hydrogen. The solution is concentrated in a vacuum. PHOSPHORIC ACIDS: *Orthophosphoric acid*, $H_3PO_4 = PO(OH)_3$: a white crystalline solid; melts at 42°; it is difficult to crystallise, and is usually met with as a thick syrupy liquid. It is extremely soluble in water. On heating to 213° it

forms *Pyrophosphoric acid*, $H_4P_2O_7$, $2H_3PO_4 = H_2O + H_4P_2O_7$. Orthophosphoric acid is tribasic. It is obtained by the action of phosphorus pentachloride (*q.v.*) on water; usually by boiling red phosphorus with nitric acid. On the large scale an impure acid is made by the action of sulphuric acid on bone ash (*q.v.*), $Ca_3(PO_4)_2 + 3H_2SO_4 = 3CaSO_4 + 2H_3PO_4$. *Pyrophosphoric acid*, $H_4P_2O_7$, is an indistinctly crystallised solid. It is soluble in water, and its solution slowly—quickly when warmed or in presence of a strong acid—changes to orthophosphoric acid; it is a tetrabasic acid. The silver salt is white. It is obtained as mentioned above or from its sodium salt (which is formed by heating common sodium phosphate) by precipitation with lead acetate, and decomposition of the lead salt with sulphuretted hydrogen. *Metaphosphoric acid*, $H_2P_2O_6$ (Glacial phosphoric acid), a glassy or ice-like solid; deliquescent; vapour density accords with the formula $H_2P_2O_6$; its solution changes just like that of the pyrophosphoric acid, to orthophosphoric acid; it gives a white silver salt, and coagulates albumin. It is obtained by strongly heating either of the two preceding acids; also by the action of water on phosphoric oxide. The more important phosphates are described under the compounds of the corresponding metals. Phosphorus unites with alcohol radicals just as nitrogen does to form compounds like the amines. Thus, triethyl phosphine, $P(C_2H_5)_3$, and tetra-ethyl phosphonium iodide, $P(C_2H_5)_4I$, are obtained by heating phosphonium iodide with ethyl iodide under pressure.

Phosphotungstic Acid (*Chem.*) *See* TUNGSTEN AND ITS COMPOUNDS.

Photo Chemical Effects. Chemical changes produced by the action of light. *See* PHOTOGRAPHY, *etc.*

Photochromy. The reproduction of colours by photography. *See* PHOTOGRAPHY IN COLOURS.

Photochronograph (*Astron.*) A small apparatus fitted to the eye end of a transit instrument for recording photographically the transit wires, the time, and the star trail.

Photo Engraving. The production of engraved plates by means of photographic processes. Trade terminology has divided photo engraving into three classes. (1) PROCESS: The production of typographic printing blocks (halftone blocks) from ordinary photographs, wash drawings, etc. (2) PHOTO ENGRAVING: The production of relief plates for use with type, from black and white subjects in *pure line*. (3) PHOTOGRAVURE: Intaglio plates on copper (afterwards faced with steel) for the reproduction of paintings, etc., in monochrome. The first and second have displaced wood engraving and, to some extent, lithography. The third has largely replaced mezzotint engraving and steel plate engraving. The reproduction of subjects in pure line is practically coeval with the art of photography, the Ordnance Survey Department having employed photo engraving for the reproduction of maps and plans soon after the introduction of photography. The production of halftone engravings was not accomplished until about half a century later. (1) HALFTONE ENGRAVINGS: In reproducing photographs or wash drawings the result is obtained by breaking up the continuous tone of the original into stipple or grain, the process being as follows: A *negative* is made from the original on a wet collodion plate or on a dry gelatine plate, the former being much more commonly used; but at a short distance in front of the sensitive plate is placed a transparent screen, formed of two sheets of glass cemented together with Canada balsam, both sheets being ruled and placed so that the lines cross each other. The lines are absolutely opaque, and vary in number according to the purpose for which the work is required, *e.g.* 80 lines per square inch are used for a coarse grain block, and up to 200 or more for fine art illustrations. The screen causes the highlights of the original to be represented on the negative as round transparent dots, which gradually enlarge as the tone of the original darkens. A pure halftone resembles a chessboard pattern of opaque and transparent perfect squares. Continuing the ratio of tone, the transparent squares gradually enlarge, until the darkest parts of the original are represented by minute opaque pin points. A copperplate, prepared by polishing with charcoal or precipitated pumice powder, is then sensitised by coating with an even film of bichromated fish glue. Light acting upon this compound renders the substance insoluble in cold water. A positive image is therefore obtained by placing the negative in contact with the sensitised metal surface, and exposing in a pressure frame to the electric "arc" or sunlight, the length of time varying from one to thirty minutes, according to the degree of sensitiveness of solution, the quality of negative, and the actinic power of the light. After exposure, the plate is put into a tray of cold water to develop, and every part of the film upon which light has not acted, owing to the opaque portions of the negative, is readily dissolved. The result is an invisible positive image, rendered insoluble by the light passing through the transparent parts of the negative. The image is at once made apparent by staining the film with a weak solution of aniline dye, which is allowed to flow over it. After drying, the metal plate is slowly and evenly heated to a temperature of about 340° to 400° C., the insoluble image of soft glue being thereby converted into a hard carbonised film. When cool the plate is immersed in an etching mordant of ferric perchloride, ranging in strength from 25° to 48° Beaume, the carbonised image resisting the dissolving action of the mordant, whilst the intervening spaces and points of bare metal are readily attacked. From two to five minutes are sufficient to etch the plate to a suitable depth, so that the image may be left in relief. Theoretically, an impression from this plate should be a facsimile of the original; but the process has to be modified to meet certain technical difficulties, one of these being that the lighter tones of the original are rendered more or less dull through the interposition of the cross lined screen, thus causing a diffused shadow to be thrown over those parts on the negative. This is remedied by passing the plate on to a "Fine Etcher," who, being possessed of some artistic ability, covers those tones which, on the copperplate, are correspondingly correct with the original, with an acid-resisting varnish. It is then again immersed in the etching mordant. If necessary, the process is repeated by covering the next lighter tones and further etching. The intervening spaces between the carbonised film are thus gradually etched wider, until the highest lights of the original are (if white) represented by minute pin points, or, in some cases, etched or cut away altogether. An impression on paper may be obtained by inking the plate with a gelatine roller charged with letterpress ink and passing it through a press. After cutting away the surplus edges by special machinery, the plate is mounted on oak or mahogany wood, and

planed to a certain gauge, so that any block may be printed with any type matter in an ordinary typographic machine. (2) A similar method is used for reproducing LINE DRAWINGS, but the absence of tone does away with the necessity of using a screen. The metal generally used is zinc, and the etching mordant, nitric acid, varying in strength from one or five to twenty parts water. The sensitive film also differs in that bichromatised albumen is generally used. After coating the plate with the sensitive solution and exposing to light, the plate is inked over by means of a gelatine roller with a very thin film of lithographic transfer ink, and developed by placing in a tray of cold water, the action of light on the albumen film also rendering it insoluble. By gently rubbing with a tuft of cotton wool, that part unacted upon by light is washed away, leaving an insoluble image of the line drawing thinly coated with a greasy film of ink. Finely powdered bitumen is then dusted over, and adheres to the ink. After carefully washing off excess of powder and drying, the plate is gently heated, the bitumen melting and forming with the ink a firm acid resisting image. After cooling, the image is obtained in slight relief by immersing for a short time in a weak aqueous solution of nitric acid (one part to twenty parts water). The image is further protected by rolling over another coating of fatty ink by means of a lithographic "nap" roller, and dusting with resin and resinous powder, commercially known as "Dragon's blood." After heating sufficiently to melt the resinous film and cooling, the plate is further etched, the process being repeated with increasingly stronger acid until the image is in sufficient relief for printing in press. A different resist from that used for copper is employed because the high temperature necessary to carbonise a film of fish glue would change the structure and properties of zinc, the latter metal being readily powdered at a temperature of 300° and melting at 420° C. (3) PHOTOGRAVURE: This is a general term for the various processes for producing plates for printing purposes which are the reverse of (1) and (2), *i.e.* the engraving is in *intaglio* instead of "in relief." As in the case of (1) and (2), bichromatised gelatine is the medium by which the plate is produced. A cloud of bitumen dust is allowed to settle on a plate placed inside a cabinet, the grains of bitumen being afterwards fixed to the plate by heat. The bichromatised gelatine film is now placed over this surface, and the subject printed upon it through a glass positive. The hardening process is effected by means of light, the unhardened portions being afterwards washed out. *See* (1) HALFTONE ENGRAVING. The plate is next immersed in perchloride of iron for the purpose of being etched, and is finally finished by a retoucher. Plates may also be prepared by using a grain screen instead of bitumen powder; but the result is not so satisfactory in the case of fine work. Photogravure reproduces the tones of the original drawings, etc., much more satisfactorily than the processes previously described, but the cost of producing the plates is much greater. A commercial TRICOLOUR ILLUSTRATION is produced by superimposing three prints one over the other from three halftone blocks, yellow, red, and blue, in their respective colours, resulting in a correct colour rendering of the original from which the blocks were made. The method generally employed is that known as the "direct" process. Three light filters, usually of dyed collodion, representing the three primary colours—red, green, and violet (*see* COLOURS)—are placed successively behind the lens, and three separate negatives, made on dry gelatine plates or collodion emulsion, are taken from the coloured original, the cross lined screen being placed in front of the sensitive plate, as in the case of black and white tone work. The red filter transmits all rays of light reflected from the original with the exception of its complementary colour, blue. A positive print made from this negative and etched on copper is therefore printed in the press with blue colour. The green filter has a similar action in suppressing the complementary colour, red, the block made from this negative being printed with red. The violet filter likewise suppresses the yellow, the subsequent block being printed in that colour. To prevent patterning of the screen in the three superimposed colour prints on paper, the angle of screen is so arranged that the lines for the yellow negative are crossed by those of the red at an angle of 60°, and by those of the blue at 120°. This is generally attained by adopting a revolving copy board, so that the original, instead of the screen, can be moved to the required angle for each negative. The method for etching and finishing the block is identical with that in use for ordinary black and white work.

Photographic Camera. A photographic camera consists essentially of a dark chamber. At the back is placed the sensitive plate, and in the front is the lens by which the image is projected on to the sensitive plate. The simplest type is the FIXED FOCUS CAMERA, which may be merely a rectangular box, the plate being supported by some suitable device at the end. Most cameras, however, possess some arrangements for focussing, or varying the distance between the lens and plate in order to secure a sharp image. The body is then made in two or more parts, one of which may slide in and out of the other; or the two parts may be connected by a bellows, a light-tight folding portion composed of leather kept in shape by internal strips of cardboard or other stiffening material. The operation of focussing is effected in this case by moving the front, to which the lens is attached by means of a rack and pinion. The open back carries a ground glass FOCUSSING SCREEN, on which an image is produced which is visible to the operator. When this image is in focus, the opening of the lens is closed by a cap or shutter; the screen is replaced by a DARK SLIDE, a flat box carrying the plate, shut in by a sliding cover. When placed in position the slide is withdrawn, and the surface of the plate occupies the position previously occupied by the surface of the screen. On opening the shutter or cap of the lens the image is produced on the plate. The best types of camera have a RISING and FALLING FRONT, whereby the lens may be raised or lowered, and also a SWING BACK, by which the dark slide and the contained plate may be brought into a vertical position if it be necessary to tilt the camera. This prevents the distortion of the image which would otherwise occur by pointing the camera upward or downward, and is essential in photographing architectural objects. A FOLDING CAMERA is one in which the bellows can be compressed into a small space, bringing the back and front close together, in order that great portability may be obtained. A MAGAZINE CAMERA is one in which a number of plates or films are contained, some mechanical device being fitted to enable a fresh plate to be placed in position after an exposure has been made, and the exposed plate to be removed to a position in which it will no longer be acted on by

light. Various devices are now in use by which DAYLIGHT LOADING is effected, *i.e.* a fresh supply of films can be introduced and the exposed ones removed without a darkroom. There are two main ways of doing this. In the first method the films are cut to size and arranged in a pile like a pack of cards, each film being separated from the next by a sheet of black paper; the whole pile is protected by a light-tight covering, which can be removed after the films are introduced. In the second, which is the more popular method, the film is made in a continuous sheet, and rolled up on a reel in contact with a sheet of black paper, of which the ends are left long enough to furnish several turns round the outside of the spool, in order to exclude light. The spool is placed inside the camera, and the film wound off on to another reel as required for each exposure. When all the film has been exposed, the second reel is full, and the film is again protected by several layers of the black paper, enabling the exposed film to be removed with safety. *See also* PHOTOGRAPHY *and* PHOTOGRAPHY IN COLOURS.

Photographic Telescope (*Astron.*) A telescope so arranged that the photographic plate replaces the eye.

Photography. The art of obtaining images by the chemical agency of light upon sensitive substances. The darkening effect of light on silver chloride was noticed by the alchemists in the sixteenth century, and furnished a good example of photographic action, the nature of which was afterwards investigated by Scheele. The first attempts to practically utilise the darkening of silver salts by light appears to have been made by Wedgwood and Davy about 1802. A sheet of white paper or leather was coated with a strong solution of silver nitrate and dried, the objects intended to be copied being either placed in contact or their shadows projected upon it. Upon exposure to sunlight, the parts protected by the objects remained white, while those surrounding them darkened under the influence of the sun's rays. Experiments of this and similar natures were, however, rendered comparatively valueless from the want of means for fixing the images, and so preventing any further action of light from taking place, the unaltered silver salt remaining in the white portions of the paper gradually darkening. In many cases, however, the action of light is invisible, and agents technically known as developers have to be employed to bring the minute change effected by light to the cognisance of our senses. In the Daguerreotype process, where an invisible action of light is produced on a silvered copperplate, rendered sensitive by exposure to the vapour of iodine, the development is accomplished by means of mercury, the vapour of this attaching itself to the substance altered by light, but whether from a physical or chemical cause is uncertain. In the process patented by Fox Talbot in 1841, under the name of Calotype, in which the sensitive material consists of silver iodide formed upon paper, the development was effected by means of gallic acid, a method discovered by the Rev. J. B. Reade. Owing to the suggestion of M. Le Gray, of Paris, of the possible use of collodion in photography, and its practical application by Scott Archer in 1851, such a stimulus was given to the progress of the art that it soon began to assume the importance it has since attained. In this collodion process, a glass plate, coated with collodion containing iodides and bromides of metals or alkalis, is immersed in a solution of silver nitrate, a sensitive surface consisting of iodide and bromide of silver being thus formed. The plate is then exposed wet in the camera, and the image afterwards developed by means of an acid solution of pyrogallol or sulphate of iron, the silver reduced from the silver nitrate present being deposited upon the parts altered by light. Although very fine photographs can be obtained upon wet collodion, the necessity of preparing the plates at the moment required, and obtaining the finished results without delay, are disadvantages, and the process (except in the case of certain classes of work) has long been superseded by the use of gelatino bromide dry plates, the sensitiveness and keeping properties of the latter rendering them available in cases that are practically impossible with the former. With dry plates and those which do not contain silver nitrate, a method of developing the invisible image, known as alkaline development, is employed, in this case the developer directly acting upon those parts affected by light, and so reducing the sub-salt of silver forming the invisible image to metallic silver. This in its turn combines with silver bromide to form mechanically fresh sub-bromide, which becomes reduced by the developer as before. And if the image be a negative one, such as results from exposing a plate in the camera under ordinary conditions, it would, when viewed by transmitted light, show all the lights and shades in the objects represented, reversed. After the image has been developed, an operation technically known as fixing is employed to remove the unaltered silver salts from the film. In the wet collodion process this is usually accomplished by means of potassium cyanide, but in the case of gelatine plates sodium thiosulphate (hypo) is used instead, owing to the danger of cyanide attacking the half tones. It frequently happens, especially with gelatine plates developed with some of the recent developers, that the negative after fixing is found to be too thin for printing, and resort has to be had to intensification. There are various methods in use for this purpose, those with mercury usually being employed with gelatine plates. The image, being bleached in a solution of mercuric chloride or bromide, is well washed, and converted into a grey or black colour by means of a solution of sodium sulphite, ammonia, silver cyanide, or a ferrous oxalate developer, this latter offering the extra advantage of permanency in the intensified image. Of methods for reducing the opacity of negatives, that with potassium ferricyanide and hypo is perhaps most generally used, although for reducing the contrasts in them a 2 per cent. solution of ammonium persulphate is found valuable. From the observations of Dr. Vozel in 1873, that the addition of dyes to silver salts increased their sensitiveness to certain colours, we owe a discovery of very considerable importance, and one which has since received practical application in the use of orthochromatic plates. In order, however, to obtain any appreciable difference in the results when using them for ordinary work by daylight, a yellow screen must be employed to cut off some of the blue rays, as the sensitiveness to blue and violet still predominates. The selection of this screen is a matter of importance, since if it be too deep in colour it may cut off the blue and violet entirely. For the best results it should be one that is adjusted to the plate. When this is not the case, it is perhaps advisable that the one chosen should not require an increase of exposure of more than six or eight times. A screen can often be employed

with advantage in hand camera work, although in most cases it must not more than double the ordinary exposure required. Of the various printing processes, those in which the image is printed out on gelatino chloride, collodio chloride, or albuminised papers, and afterwards toned with gold, are largely used, while the numerous development papers offer the great advantage of rapidity in the production of the prints. For permanency, however, platinum and carbon stand unrivalled. Modifications of the carbon process have been introduced under the names of Artigue and Ozotype, in which the image is printed direct upon its final support. The former, however, while yielding very fine results, requires a good deal of care in manipulation, while the latter only needs that necessary in carbon printing generally. —E. S.

Photography in Colours. The methods by which objects can be represented photographically in colours may be classed under two heads: (1) The direct method, in which a light-sensitive substance is capable of reproducing the colours which fall upon it. (2) The indirect method, which is dependent upon the superposition of coloured images (usually three), and which is known as the three colour process. DIRECT METHOD: The colours are due either (1) to interference, as in the case of the Becquerel and Lippmann process, or (2) when paper coated with silver chloride is used, such as Seebeck employed, are of a pigmentary nature. In this process of Dr. Seebeck, which dates back to 1810, a solar spectrum was projected upon paper prepared with moist silver chloride, and an image obtained somewhat resembling the spectrum colours. The chief worker, however, in this subject, M. Edmond Becquerel (the first published account of whose work appeared in 1848), obtained his best results upon chlorinated silver plates, the particular method of chlorination adopted being that in which the chlorine was produced by the electrolysis of dilute hydrochloric acid, the nascent chlorine uniting with the silver. This method had the advantage of greater control over the thickness of the film of chloride formed, as when the violet colour was assumed for the second time the silver plate was removed from the bath, washed in distilled water, and dried at a gentle heat, the plate being then sensitive to all spectrum tints. The colours are, according to Wiener, partly pigmentary and partly due to interference. A great disadvantage attending this process was that the coloured images could not be fixed. By far the most important method of producing direct photographs in colour is that due to Professor Gabriel Lippmann, and first announced by him in 1891, and is based on the theory and work of Zenker and Wiener. The process, which is very simple, consists in employing a plate of glass coated with a perfectly transparent sensitive film of silver bromide in gelatine, together with suitable colour sensitising dyes, and having in contact with the film during exposure in the camera a metallic mirror in the form of a layer of mercury. The latter is for the purpose of reflecting the light back upon itself. This gives rise to stationary waves within the film, with the result that, after development and fixing, the image is formed of a laminated deposit of silver, separated by transparent layers of gelatine, the thickness of each transparent layer being equal to half the wave length of the light used during exposure. When these photographs are viewed by white light incident normally upon them, waves equal in length to those used during exposure will be reflected back to the eyes, and thus the film will appear of the same colour as the light to which it had been exposed. When viewed obliquely the colours change, red becoming successively yellow, green, and blue. To enhance the brilliancy of these photographs, and at the same time eliminate disturbing surface reflections, a shallow glass prism is usually cemented to the film with Canada balsam. The INDIRECT METHOD of colour photography is based on the theory of Dr. Thomas Young, who found that any colour could be produced by the mixture in various proportions of three colours properly chosen. Professor Clerk Maxwell, who supported this theory, appears to have first suggested how to carry it into practice by the aid of photography in a lecture delivered at the Royal Institution on May 17, 1861. The particular colours to employ, and the proportions in which they must be mixed to represent all intermediate spectrum hues, was first determined by Maxwell, and are shown in his famous diagram of colour mixture curves. These curves have quite recently (1899) been re-determined by Sir William Abney, whose results differ somewhat from the former; and the three simple colours which, when mixed in suitable proportions, will reproduce to the eye the sensation of every other spectrum colour, have been found to be: a red situate about the lithium line in the red; a green near the E line in the green; and a blue violet about the blue lithium line. In order, therefore, to obtain a three colour photograph of the spectrum, three photographs must be taken, in each of which photographic action must be so distributed that it would be represented graphically by the respective curves in one of these diagrams. In order to realise this in practice, the negatives are taken through light filters (colour screens), which should transmit light in accordance with the colour curves; such light filters, if they enable correct colour records of the spectrum to be obtained, should answer equally well in the case of landscapes, or coloured objects generally, since their colours are only mixtures of spectrum colours. As these filters require to be adjusted to suit the sensitiveness of the plates employed, they can only be described in general terms as being red, green, and blue violet in colour. Positives made from the negatives taken by their use, when backed by media allowing only pure colour to pass, will, when their images are superimposed on a screen, reproduce the colours of the original; but if prints are to be produced, the prints must be made in colours which are complementary to the three colour sensations. These principles appear to have been recognised by Louis Ducos du Hauron in 1868. To Mr. F. E. Ives, however, must be given the credit of bringing the process to the state of perfection it has now reached. He pointed out the necessity of using screens which transmit pure colour only for correct synthesis, as distinct from the colour curve screens used in taking the negatives; and by means of his ingenious viewing apparatus the kromscop completed a most perfect method of composite heliochromy. When finished prints for use as transparencies or projection in a single lantern are required (a system of three colour photography brought to such perfection by Sanger Shepherd and Messrs. Lumière), the positives are usually made upon gelatino bromide celluloid films sensitised with bichromate, and after development and fixing are stained the complementary colours in aqueous solutions of dyes. In the case, however, of the positive from the red record negative, it is found better to make this upon a lantern plate, and convert it into the required blue colour with potassium ferricyanide, followed after washing with ferric

chloride. The films are then cemented together between glasses, and form a finished transparency in colours. A method suggested by Dr. Hauron in 1869 for obtaining the three colour records on one plate, and put into practice by Professor Joly, of Dublin, consists of exposing the photographic film in contact with a glass plate placed in front of it, ruled in transparent coloured inks, with red, green, and blue violet lines. These coloured lines, which correspond to the colour filters used in taking the record negatives in Ives's process, number about 260 to the inch, and the order in which they are ruled is repeated throughout the plate, which by transmitted light appears of a light grey colour. Negatives taken through such a screen will be crossed by a series of lines of deposited silver corresponding to the amount of light which acted through the respective lines, and a positive made from such a negative when placed in contact, and "correct register" with a similar lined screen, but ruled in colours which stimulate respectively the three colour sensations of the eye, will, when viewed directly, show the image in colours. A variation of the three colour process, due to Professor R. W. Wood, which does away with the necessity of using coloured screens or pigments for the finished pictures, consists in employing three diffraction gratings, each ruled with such a number of lines to the inch that, when superposed in front of a lens, they will send red, green, and blue light to the same spot on a screen behind it, which by their mixture will convey to the eye the sensation of white light. To produce a picture in colours by this method three negatives are taken through red, green, and blue violet colour filters as usual, and from these positives are made on lantern plates. A piece of glass coated with bichromated gelatine (or albumen) is placed with its sensitive film in contact with a grating bearing 2,000 lines per inch, and the whole covered with the positive representing the action of the red light. An exposure of a few seconds to sunlight will impress the lines of the grating on the bichromated film under the transparent parts of the positive. The second grating, consisting of 2,400 lines per inch, and the positive, representing the action of the green light, are now substituted for the others, and a second exposure given. The same is then repeated for the blue, using a grating having 2,750 lines per inch, and the positive which represents the blue. The plate is then washed for a few minutes in warm water, and on drying the image appears as a coloured photograph when placed in front of a lens and viewed through an aperture in a screen. The finished picture, which is perfectly transparent, merely consists of a diffraction grating on gelatine, with variable spacing. Some progress has also been made towards realising in practice Wiener's idea for an ideal colour sensitive surface, in which three films stained red, blue, and yellow with fugitive dyes, are combined to form a black or neutral tint. Such a surface will, with prolonged exposure, under a coloured transparency, yield a more or less perfect reproduction of the coloured image. A means of thoroughly fixing these images, however, still remains to be found.—E. S.

Photometers. A photometer is an instrument for comparing the illuminating powers of two sources of light. All such instruments in common use depend upon the fact that the eye is capable of judging with considerable accuracy when two surfaces adjacent to each other are equally illuminated. It is necessary that the illumination observed shall be due to the two sources only, and therefore all other light must be excluded, the measurements being made in a darkened room or other enclosure, the inside of which should be blackened, to prevent reflected and diffused light from interfering with the observations. The source of light to be tested is usually fixed at one end of a horizontal bench or bar, termed the PHOTOMETER BENCH or BAR, which is graduated in inches or centimetres; at the other end is fixed a standard light, which may be a STANDARD CANDLE, PENTANE LAMP, METHUEN SCREEN, etc. (*q.v.*) At a point between the two lights is fixed the PHOTOMETER proper. Let I be the intensity of one of the two sources, then at a distance d the intensity of illumination is $\frac{I}{d^2}$. If I_1 and I_2 be the relative intensities, d_1 and d_2 the distances of the two sources from the photometer, then when the latter is receiving the same amount of light from each source,

$$\frac{I_1}{d_1^2} = \frac{I_2}{d_2^2}, \text{ or } \frac{I_1}{I_2} = \frac{d_1^2}{d_2^2}$$

The form of photometer most used in practice is BUNSEN'S PHOTOMETER (*q.v.*) Observations with this instrument are usually made with the aid of two mirrors placed behind the screen, and inclined at 90° to each other and at 45° to the screen; by this means both sides of the screen may be viewed at the same time, and the position of the photometer with reference to the two sources adjusted with considerable accuracy until the spot appears of the same brightness as the rest of the surface of the screen. JOLY'S PHOTOMETER consists of two flat plates of translucent paraffin wax placed in contact, with a sheet of tinfoil between them. When placed between two sources of light and viewed edgewise, each plate appears to be illuminated; when both appear equally bright, the intensities of the two lights are proportional to their distances from the screen. The LUMMER-BRODHUM PHOTOMETER consists of an opaque white screen, one side of which is illuminated, by each of the sources of light which are being compared. An ingenious arrangement of mirrors and reflecting prisms enables the central portion of one surface of the screen, and the outer portion of the other, to be viewed at one time. If the two sides of the screen are not equally illuminated the eye sees a bright patch surrounded by a dark zone, or *vice versa*. Adjustments are made until the inner and outer zones are equally illuminated. When this is the case the two surfaces must be equally illuminated, and therefore the intensities of the two sources are proportional to the square of their distances from the screen. A simpler arrangement, which possesses the advantage that it may be used in a room which is not quite dark, is RUMFORD'S SHADOW PHOTOMETER. This consists of an opaque rod, a shadow of which is cast on a white screen by each of the two lights, which are moved backwards and forwards until the intensities of the shadows are the same. The intensities of the lights are then proportional to the square of their distances from the screen.

Photometry (*Light*). The comparison of the intensity of a given source of light with a standard source by means of a PHOTOMETER (*q.v.*)

Photomicrograph. A photograph of a microscopic object obtained by attaching the camera to the microscope tube.

Photospectro Heliograph (*Astron.*) An instrument for recording photographically a picture of the

sun's disc and limb in colour of one wave length or monochromatic light. The "K" line of calcium is the light usually employed.

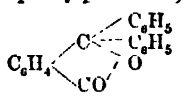
Photosphere (*Astron.*) The sun's visible surface.

Phototype. A general name for copying processes based upon photography. *See* BLUE PRINT.

Phrase (*Music*). The subdivisions of a musical sentence or period are called phrases, two or more of which form a period.

Phrygian Mode (*Music*). *See* MODES.

Phthaleins (*Chem.*) Substitution products of phthalophenone (diphenylphthalide),

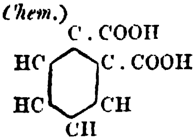


But the Phthaleins are not usually prepared from phthalophenone; they are prepared by heating phenols with phthalic anhydride in presence of a dehydrating agent, such as sulphuric acid or zinc chloride. For examples of phthaleins, *see* PHENOL-PHTHALEIN, FLUORESCEIN, EOSINE. That phthalophenone has the constitution assigned to it is proved by its synthesis by Friedel and Craft's reaction (*q.v.*) from phthalylchloride and benzene:

$$C_6H_4 <\begin{matrix} C.Cl_2 \\ CO \end{matrix}> O + 2C_6H_6 = C_6H_4 <\begin{matrix} C(C_6H_5)_2 \\ CO \end{matrix}> O + 2HCl$$

Also phenol-phthalein (*q.v.*) can be synthesised from phthalophenone by nitration, reduction, and diazotisation. The RHODAMINES (*q.v.*) are also Phthaleins.

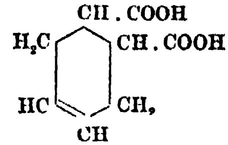
Phthalic Acid (*Chem.*)



A colourless crystalline solid (prisms); melts at 203° if quickly heated, and forms the anhydride with loss of one molecule of water:

$$C_6H_4 <\begin{matrix} COOH \\ COOH \end{matrix} = C_6H_4 <\begin{matrix} CO \\ CO \end{matrix}> O + H_2O.$$

Sparingly soluble in cold water; readily soluble in hot water and in alcohol. It is a dibasic acid, forming two classes of salts and esters. Heated with soda lime it gives first benzoic acid, then benzene. It is prepared by oxidising naphthalene tetrachloride with nitric acid. *See* p. 447. It is also prepared, in the form of its anhydride, on a large scale for the preparation of indigo. *See* INDIGO. Phthalic acid can unite with two, four, or six hydrogen atoms, and so give rise to many hydrophthalic acids; thus, theoretically it would give six dihydrophthalic acids. Of these, four are known: the $\Delta^{3,5}$-dihydrophthalic acid (*see* NOMENCLATURE) can exist in two forms, known as the cis- and trans-forms. The cis-$\Delta^{3,5}$-dihydrophthalic acid has the two carboxyl groups on one side of the benzene ring, while the trans- acid has them on opposite sides. The cis- acid readily forms an anhydride; the trans-acid forms an anhydride with difficulty, and the anhydride formed is that of the cis- acid. The trans-$\Delta^{3,5}$-dihydrophthalic acid is obtained by reduction of phthalic anhydride in acetic acid solution by sodium amalgam; it passes into the cis- acid on heating with acetic anhydride. Three tetrahydrophthalic acids are known, of which the Δ^4 compound,



is known in the cis- and trans- modifications. The hexahydro acid is known in the cis- and trans- forms, and the latter, which contains an asymmetric carbon atom, can be resolved into its optically active components by means of quinine. *The anhydride of phthalic acid*,

$$C_6H_4 <\begin{matrix} CO \\ CO \end{matrix}> O,$$

forms long, shining, needles; melts at 128°; boils at 284°; slightly soluble in water; very soluble in alcohol and ether. On heating, it easily sublimes. Alkalis readily form salts of phthalic acid with it. With one molecular proportion of phosphorus pentachloride on heating it gives phthalyl chloride, which behaves in many of its reactions as if it has the constitution

$$C_6H_4 <\begin{matrix} C.Cl_2 \\ CO \end{matrix}> O;$$

e.g. with zinc and acetic acid it yields phthalide,

$$C_6H_4 <\begin{matrix} CH_2 \\ CO \end{matrix}> O$$

See also PHTHALEINS. Heated with phenols, the anhydride gives Phthaleins (*q.v.*) The anhydride is obtained by heating phthalic acid alone or with acetyl chloride. *Phthalimide*,

$$C_6H_4 <\begin{matrix} CO \\ CO \end{matrix}> NH,$$

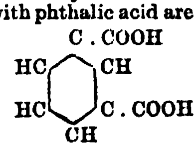
is a white crystalline solid (prisms); melts at 229°; soluble in ether; sublimes on heating. With alcoholic potash it forms a well crystallised potassium salt, potassium phthalimide,

$$C_6H_4 <\begin{matrix} CO \\ CO \end{matrix}> NK$$

This salt reacts with alkyl iodides, forming alkyl phthalimides, which are converted by alkalis into phthalates and primary amines:

$$C_6H_4 <\begin{matrix} CO \\ CO \end{matrix}> N.C_2H_5 + 2HOK = C_2H_5NH_2 + C_6H_4 <\begin{matrix} COOK \\ COOK \end{matrix}$$

For a very important reaction of phthalimide, *see* INDIGO. Phthalimide is obtained by heating phthalyl chloride or phthalic anhydride in a stream of ammonia gas. Isomeric with phthalic acid are isophthalic acid,



and terephthalic acid; the former is not an important compound, the latter is treated by itself. Neither of the isomers of phthalic acid forms an anhydride.

Phyllite (*Geol.*) A rock of argillaceous composition, and usually of sedimentary origin, which

has been subjected to dynamic metamorphism, with the result that the microscopic fragments of potash felspar occurring in the parent rock have been paramorphosed into flakes of Muscovite, which have a common orientation throughout the rock, and thus facilitate its separation into thin sheets in the same manner as slates. These scales or flakes of mica usually impart a peculiar silky lustre to the face of a phyllite which has been split up by mechanical means.

Phylloporphyrin (*Chem.*) $C_{16}H_{18}N_2O$. A decomposition product of chlorophyll. It forms short reddish violet prisms; soluble in chloroform; less soluble in ether or alcohol; gives red fluorescent solutions. It shows an absorption spectrum of seven bands, which closely resembles that of hæmatoporphyrin from hæmoglobin (*q.v.*), and it appears to differ from this substance only in containing two oxygen atoms less; corresponding to this phylloporphyrin is insoluble in aqueous alkalis, while hæmatoporphyrin is readily soluble. Like hæmatoporphyrin (*see* HÆMOGLOBIN), it yields as products of oxidation and reduction respectively hæmatinic acid and hæmopyrrol. The compound mesoporphyrin (*see* HÆMOGLOBIN) is intermediate between phylloporphyrin and hæmatoporphyrin.

Physical Astronomy. The branch of astronomy dealing with the composition, temperature, etc., of heavenly bodies. It owes its existence almost entirely to observations by the spectroscope. *See* SPECTRUM ANALYSIS.

Physical Isomerides. A name given to compounds which have the same constitutional formula, and therefore the same chemical reactions, but have different physical properties. The difference in physical properties is caused by the different spacial arrangements of the atoms or atomic groups in these compounds. *See* STEREOISOMERISM.

Physics. The term Physics originally referred to the study of Nature and natural phenomena in general; it is now restricted to the study of the properties of matter and of natural forces and phenomena which are neither organic nor chemical in their nature. There is no hard and fast boundary line, however, between physical and chemical phenomena.

Physio-Chemical Engineering. ORIGIN AND HISTORY: Throughout this Dictionary a number of definitions are given under the classification of *Chem. Eng.*, and some explanation of this classification is necessary. The term is a shortened form of what is really Physio-Chemical Engineering, a profession, or branch of the engineering industry, which has only been recognised during the last fifteen or twenty years. Strictly speaking, it is an offshoot of engineering which has arisen out of the needs of the chemical industry, and finds a parallel in electrical engineering, though perhaps there is more engineering than electrical knowledge required for the latter, while in chemical engineering there is need for a more general knowledge of each component. On the other hand, so-called chemical engineering is of a more complex nature than the name implies, and for this reason it is thought preferable to deal with the subject under Physio-Chemical Engineering. The present Society of Chemical Industry started as a Society of Chemical Engineers, but the title was thought to be too exclusive at that time. The need for a chemical engineer arose out of the industrial developments of chemistry. Processes were worked out in the laboratory, but when it came to working on a manufacturing scale, glass vessels and indiarubber tubing were inapplicable. The mechanical engineer had to devise and construct as best he could suitable plant and apparatus with which to carry out processes on a large scale. In time it became evident that many processes were impracticable for want of better chemical plant. The chemist consulted the engineer, and the latter endeavoured to construct what was needed. Seeing the scope afforded, some men specialised and made themselves acquainted with all that engineers were doing or had done, and applied the knowledge so acquired. Hence the chemical engineer. Since then there has been much controversy as to what are the qualifications of a chemical engineer. There is little doubt, however, that a knowledge of chemistry and physics is of more importance than detailed knowledge of mechanical engineering, though a practical acquaintance with the latter is a great help, and some knowledge essential. DEFINITION: To define Physio-Chemical Engineering is obviously no easy task. The definition must necessarily be rather involved, as it includes a knowledge of chemistry, physics, civil and mechanical engineering. Perhaps the most concise definition is this: The adaptation of materials to methods, in doing which the three chief qualifications are common sense, observation, and ingenuity. APPLICATIONS: Physio-Chemical Engineering deals with the manipulation, control, and transport of the gases, liquids, and solids which result from or are essential to chemical reactions on a manufacturing scale. These bodies may be hot or cold, inert or corrosive, volatile or stable, as well as explosive or inflammable. An accurate knowledge of their chemical and physical properties is necessary before suitable plant for their manipulation can be evolved. In the same way constructional details have to be modified to meet the various methods for their solution, decomposition, lixiviation, precipitation, filtration, evaporation, distillation, concentration, or condensation. This involves a study of the materials which will withstand the forces exerted by such gases, liquids, and solids while undergoing chemical change and the consequent variations in their physical conditions. It will be seen, therefore, that Physio-Chemical Engineering is a very extensive branch of engineering, and is not easily defined, more particularly as in this relationship chemistry and engineering are so largely interdependent. Undoubtedly to the chemical engineer is due the evolution of certain plant and apparatus which otherwise might never have been thought of. The filterpress, centrifugal dryer, steam trap, and Montejus or acid egg, are four striking examples. In the first two the engineer turned well known forces to account. The development of steam coils for heating in all branches of chemical industry created a demand for an effectual means of removing condensed steam without letting live steam escape; while in the transport of corrosive fluids the lead-lined acid egg took the place of the old type of pump, with compressed air substituted for the plunger or piston. As the result of these changes the engineer on the mechanical side perfected the existing air compressing and exhausting engines, and enabled the manufacturer to use compressed air, vacuum pans, and multiple effect evaporation with economy. Yet chemical knowledge is largely fundamental in effecting improvements. In the aniline dye industry the supply of concentrated vitriol to almost every department of the works is necessary. Cast iron pipes and compressed air exist, but it needs the reassurance of the chemist that cast iron is

practically unattacked by strong vitriol (although dissolved by weak) before the engineer is able to employ the two, and so transport the acid to any part of the works with ease and safety. In the same way the chemist has co-operated with the engineer in producing acid-resisting alloys or other material for taps, valves, packings, washers, and other engineering accessories suitable for chemical plant. Disintegrators, mechanical agitators, steam jet heaters and agitators have also been adapted to the special requirements of chemical engineering. The soap industry, however, affords an excellent example of how purely engineering skill has been devoted to the production of special plant (for which only a knowledge of physics and engineering was essential), notably in connection with the cooling, drying, shredding, and milling of soap. The introduction of carborundum also affords an instance of how the electro chemist comes to the aid of the chemical engineer by providing an acid and heat resisting material for furnace linings and allied uses. It is not possible in a short review such as this to do more than indicate thus the varying phases of chemical engineering, in order to show how comprehensive the term is, and consequently so difficult to define. In the future it is probable that the term will become as generic as that of civil engineering, and include a number of industries in which chemical plant is used, but which are known by the name of the actual product produced. For instance, the gas engineer is largely a chemical engineer, or should be: but, owing to the present magnitude of this particular industry, the title of Gas supplants the more general one of Chemical. LITERATURE: There is very little available literature *per se*, as most of it is to be found in articles contributed to almost all classes of technical journals. Chemical engineering itself, even then, is seldom kept separate from works' management, organisation, and administration, but is dealt with only in so far as equipment bears upon these subjects. As for text books they can hardly be said to exist. For many years trade catalogues constituted the nearest approach to anything of the kind, and even now are often the best source of information. Of late the pick of such catalogues has been collected, classified, and occasionally supplemented by notes, and then presented in this condensed form as a handbook. Useful as this handier form undoubtedly is, the fact remains that condensed catalogues interspersed with a smattering of Trautwine and Molesworth are the only chemical engineering literature that exists, apart from scattered articles, most of which are very restricted in scope and aspect. Thus its bibliography reflects and confirms the heteroclitic nature of Physio-Chemical Engineering. The important influence which it does, and must, exercise on the technics of the future may result in its ultimately assuming a more definite and conventional position as a business or profession.

C. H. N.

Physostigmine (*Chem.*) *See* CALABAR BEAN.

Piacere, A (*Music*). At pleasure.

Piacevole (*Music*). Agreeably, pleasantly.

Pianette (*Music*). A small pianoforte.

Piangendo, Piangevole (*Music*). In a plaintive manner.

Pianissimo (*Music*). Very soft. Abbreviation, *ppp* (or *pp*).

Piano (*Music*). Soft. Abbreviation, *p*.

Pianoforte (*Music*). *See* MUSICAL INSTRUMENTS (STRINGED).

Piatti (*Music*). The Italian name for cymbals. *See under* MUSICAL INSTRUMENTS.

Piazza (*Architect.*) A rectangular open space surrounded by buildings or colonnades.

Pibroch (*Music*). The Scottish military music of the bagpipe.

Pica (*Typog.*) Type between English and small pica in size. The body of this type is generally used as the standard for leads, measures, etc. *See* TYPES.

Piccolo (*Music*). (1) *See* MUSICAL INSTRUMENTS (WIND). (2) An organ stop. *See* ORGAN, p. 441.

Picea (*Botany*). The genus of *Coniferæ* comprising the spruce fir (*P. excelsa*), yielding turpentine, resin, and timber, and the silver fir (*P. alba*).

Pick. A pickaxe, the familiar tool used in excavation, mining, etc.

—— *or* **Shoot** (*Textile Manufac.*) A throw of the shuttle carrying weft through the shed or opening between warp threads.

Picker *or* **Driver** (*Textile Manufac.*) A device fitted in shuttle box for propelling the shuttle.

Picker Leather. Leather specially tanned for the making of picker bends used in cotton spinning, etc.

Picking (*Weaving*). The second primary movement of the loom, *viz.* the propulsion of the shuttle across the loom sley and through the warp shed (*q.v.*) In the power loom this is generally effected by cam movement operating on picking arms or levers. There are two distinct methods: (1) Overpick; (2) Underpick. *See* LOOM.

Pickle. An acid solution used for cleansing the surface of metallic objects. *See* PICKLING.

Pickling (*Chem. Tech.*) Candle wicks are pickled to prevent them burning too fast, and also avoid their leaving too much ash. Borax, sal-ammonia, and phosphate of ammonia solutions are some of those employed. The wicks are steeped, wrung out, and dried. This treatment has done away with "snuffing."

—— (*Eng.*) Removing the hard skin on metal castings by immersion in dilute sulphuric or nitric acid; also used as a general term for processes in which an acid (or occasionally another liquid) is allowed to act on metals for the purpose of cleaning, etc.

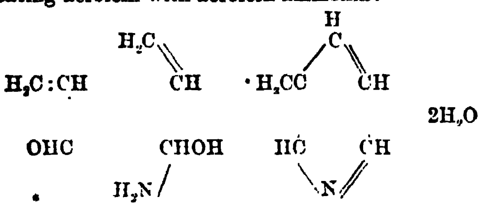
—— (*Leather Manufac.*) Sheep skins, after the wool has been removed, are pickled for export. The most common method in use is soaking the pelts in a weak solution of sulphuric acid, to which is added an excess of salt. Formic acid may be substituted for the sulphuric. *See also* CURING.

—— (*Met.*) The immersion of steel, etc., plates in dilute vitriol (*q.v.*) to remove scale and oxide prior to galvanising, or otherwise coating with a protective covering.

Picks (*Cotton Manufac.*) The term is applied to the weft threads in a cloth; sometimes termed SHOTS.

Picks (*Print.*) Blots or patches caused by dirty ink or pieces of paper or roller composition filling up the face of the letter. They are picked out with a needle or sharp pointed bodkin.

Picolines (*Chem.*) The monomethyl pyridines. *See* PYRIDINE. α-PICOLINE is a liquid; boils at 130°; on oxidation it yields picolinic acid. It is formed on heating the methyl iodide compound of pyridine in sealed tubes. It can be prepared from crude pyridine by dissolving in hydrochloric acid, and precipitating with mercuric chloride. The resulting double salt is decomposed by caustic soda. β-PICOLINE is a liquid; boils at 143°; on oxidation it gives nicotinic acid. It is obtained by heating acrolein with acrolein ammonia:

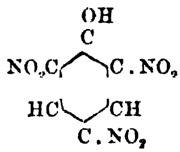


Also by heating glycerine with acetamide—

$$2CH_2OHCHOHCH_2OH + CH_3CONH_2 = C_5H_4CH_3N + CH_3COOH + 5H_2O$$

δ-PICOLINE is a liquid; boils at 144°; on oxidation it gives isonicotinic acid. It is formed along with the α-picoline when pyridine methiodide is heated in a sealed tube. It occurs in coal tar.

Picric Acid (*Chem.*) (Symmetrical trinitrophenol.)



Sometimes called carbazotic acid. Yellow crystalline solid; melts at 122°; sparingly soluble in cold water; fairly soluble in hot water. It is an acid, liberating carbon dioxide from sodium carbonate. Burns quietly on ignition; the fused acid explodes powerfully on detonation; it also explodes with great violence when heated with an oxidising agent such as red lead. It enters into the composition of a number of smokeless explosives, such as lyddite. It unites with many hydrocarbons directly, *e.g.* with anthracene and naphthalene, and the compounds so formed are useful in identifying hydrocarbons. With phosphorous pentachloride it forms picrylchloride, $C_6H_2(NO_2)_3Cl$. It is extensively used as a dye; it dyes unmordanted wool and silk a greenish yellow colour. Picric acid is formed by the action of nitric acid on many organic substances—*e.g.* resins, leather, wool, silk. It is prepared by dissolving phenol in strong sulphuric acid, and acting on the mixture of ortho- and para-phenol sulphonic acids so formed with strong nitric acid. *See also* DYES AND DYEING *and* EXPLOSIVES.

Picrotoxin (*Chem.*) The active principle of the Indian Berry (*Cocculus indicus*). Silky crystals; melts at 192° to 200° with change; sparingly soluble in cold water; fairly soluble in hot water; readily soluble in alcohol. Lævorotatory; dissolves in strong sulphuric acid with golden yellow colour; reduces Fehling's solution. It is poisonous; its solutions have a bitter taste. It appears to be a mixture of two substances, *viz.* Picrotoxinine, $C_{15}H_{16}O_6$, and Picroline, $C_{15}H_{18}O_7$.

Pie (*Typog.*) Unsorted or "broken" type indiscriminately mixed.

Piece Mould. *See* CAST (*Sculp.*)

Piecework. A system by which workmen are paid for their labour at so much for each job or piece of work, instead of being employed at a fixed rate per hour.

Pieno (*Music*). Full.

Pier (*Build.*) (1) A pillar of brick or stone. (2) The part of a wall which is made thicker, forming a vertical projection. (3) The solid parts between openings in a wall, *e.g.* where a window or door intervenes. (4) The support to which a gate is hung. *See also* ARCH.

—— (*Civil Eng.*) A breakwater or jetty built out into the sea, serving to form a harbour, a landing place, or a marine promenade.

Piezometer (*Phys.*) An instrument for experiments on the elasticity of liquids; the latter are subjected to an increase of pressure, and the resulting diminution of volume observed.

Pig (*Glass Manufac.*) An iron grooved support for the blowing or working rods. It is placed immediately in front of the mouth of the Pot, and upon the Pat.

—— (*Met.*) The bars in which various metals are cast at the conclusion of the processes of smelting. Iron is always cast in pigs weighing about a hundredweight, when it is run out of the blast furnace.

Pig Bed (*Met.*) A layer of sand in front of a blast furnace, in which open moulds are made for casting the pigs. The main channel along which the molten metal runs from the furnace is termed the Sow.

Pig Boiling (*Met.*) A method of puddling iron (*q.v.*), in which basic oxidisers are added to the metal in the furnace to remove the carbon, etc., as opposed to "dry puddling," in which oxidation is effected solely by the air in the gases, to which the metal is subjected in the reverberatory furnace.

Pigeon Holes (*Typog.*) Wide spaces between words are derisively called pigeon holes, it being the duty of a compositor to avoid them when possible.

Pig Iron (*Met.*) Iron as it comes from the smelters. It is roughly classified according to its suitability for conversion into wrought iron, steel, castings, etc. *See also* IRON.

Pigments (*Dec.*) The class of bodies, either white or coloured, which, when reduced to a fine powder and mixed with oil, japan, water, or other vehicle, form a paint (*q.v.*) Pigments are both of mineral and organic origin, white lead and ochre being examples of the former, and ivory black and gamboge of the latter. A classification of pigments may be made either according to their colour, chemical character, or their lasting properties when exposed to light and air or to the action of lime. The following lists are arranged on the last mentioned plan: Pigments which are accepted as PERMANENT: Colcothar, Indian Red, Light Red, Red Ochre, Red Oxide, Rouge, Scarlet Red, Venetian Red, Vermilion

(doubtful), Cobalt Blue, Prussian Blue, Ultramarine, Cadmium Yellow, Sienna, Yellow Ochre, Chrome Green, Cobalt Green, Terra Verte, Umber, Vandyke Brown, Lampblack, Ivory Black, Carbon Black, Barytes (Sulphate of Barium), Blanc Fixe, Charlton White, China Clay, Gypsum Lithopone, Orr's White, Satin White, Strotian White, Whiting, and Zinc Oxide. NOT PERMANENT, *i.e.* pigments more or less affected by exposure to light or sulphuretted hydrogen: Carmine, Cochineal Lake, Crimson Lake, Derby Red, Orange Red, Red Lead, Royal Red, Scarlet Lake, Signal Red, Vermilionette, Mineral Blue, Chrome Yellow, Naples Yellow, Chrome Red, Emerald Green, Green Lake, Scheele's Green, Verdigris, Sulphate of Lead, and White Lead. As a constituent of paint a pigment plays an important part. It gives solidity and strength to the film of oil, and increases its thickness; hence forms a better protection to the surface to which it is applied. It also renders the film less porous. Of white pigments which form the base of most paints the chief virtue is opacity or body (*q.v.*) It is principally because white lead possesses this quality in so eminent a degree that it is so largely used as a paint. Some pigments, such as barytes, are very deficient in this quality, but being quite inert and very durable they make good paints when mixed in small proportions with white lead.

Pigskin (*Bind.*) The tanned hide of the domestic swine. Much used for binding in the Middle Ages. Dr. Dibdin stigmatises pigskin in book binding as "the eternal engenderer of mould and mildew." It has again come into use for books that are much handled, *e.g.* for the backs of books in public lending libraries.

Pigtail Twist. A laboratory appliance for quickening the filtration of liquids where a vacuum pump is not available. It is a piece of glass tubing the same diameter as the stem of the filter funnel, with a single coil near one end. The shorter length is coupled to the funnel by indiarubber tubing. The weight of liquid in longer limb creates a "pull" on the contents of the funnel.

Pilaster (*Architect.*) A column attached to a wall from which it projects one-sixth to one-fourth of its width. The anta or pilaster used in Greek work was always treated quite differently from the detached columns, but in Roman and Renaissance work the details of the pilaster-capital and base are the same as those of the columns. The term pilaster is occasionally used to denote a detached square column. A pilaster is also known as a parastata. *See* PILASTER STRIPS.

Pilaster Strips (*Architect.*) Vertical strips of ashlar in the rubble walling of Anglo-Saxon work. *See* ANGLO-SAXON ARCHITECTURE.

Pile (*Civil Eng., etc.*) A heavy piece of timber of square section, pointed and shod at the end, driven into soft or wet ground to form foundation for masonry or part of a wall, as in the case of a cofferdam, etc.

—— (*Elect.*) (1) A primitive form of battery, due to Volta, consisting of a series of alternate discs of copper and zinc, separated by discs of cloth damped with dilute acid. (2) A THERMOPILE (*q.v.*)

—— (*Her.*) One of the ordinaries, in the form of a long thin wedge with the point downwards.

Pile (*Met.*) A number of bars of puddled iron (*q.v.*) arranged one on top of each other ready to be heated and welded together; the mass thus formed is again rolled out into bars, which are much stronger than the original bar, as the grain or fibre of the iron can be caused to run in different directions, according to the method in which the bars are piled.

—— (*Textile Manufac.*) The fibre on the surface of cloth. It may be obtained by raising, in cloths which have been felted; or developed in weaving by using wires over which the warp threads are passed and cut; or left in loops, as in Axminster and Brussels carpets, respectively.

Pile Cap (*Civil Eng.*) A horizontal beam connecting the heads of adjoining piles.

Pile Driver (*Civil Eng.*) Mechanism for driving piles into the ground. It consists essentially of a heavy weight, termed a MONKEY, which is allowed to fall from a considerable height on to the head of the pile. It is guided in its fall by two uprights, forming part of the frame of the pile driver. The weight is raised either by hand or by power.

Pile Hoop (*Civil Eng.*) A hoop or band of iron, fixed on the upper end or head of a wooden pile to prevent the timber from splitting under the blows of the falling weight or monkey of the pile driver.

Pile Screw (*Civil Eng.*) The screw at the end of a SCREW PILE (*q.v.*)

Pile Shoe (*Civil Eng.*) An iron point fixed to the end of wooden piles to enable them to enter the ground.

Piling (*Met.*) The arrangement of bars and slabs of malleable iron or steel to form bundles or "piles," which are reheated and welded into a solid mass from which sheets, rails, and merchantable iron are rolled. Experience and skill are needed in the selection of metal and method of piling for various purposes.

Pillar (*Architect.*) A disengaged column used to support an arch. Its proportions always differ from those of the orders when used in Roman or Renaissance architecture. *See* CLUSTERED PILLAR.

—— (*Mining*). A column or mass of ore or rock left *in situ* in order to support the roof of the working.

Pillar and Stall System (*Mining*). *See* MINING.

Pillar Drill (*Eng.*) A drilling machine carried by a vertical central column or pillar.

Pillar File (*Eng.*) A thin narrow file, usually with a SAFE EDGE (*q.v.*)

Pillow Block (*Eng.*) A PLUMMER BLOCK (*q.v.*)

Pilot Engine (*Civil Eng.*) An engine run in front of a train to ascertain that the line is clear, signals in working order, etc.

Pilot Lamp (*Elect. Eng*). An incandescent lamp which is used to indicate roughly when the voltage of a dynamo, storage battery, etc., has its proper value.

Pilot Wires (*Elect. Eng.*) Wires leading from a particular point in a circuit to enable tests of the voltage, etc., at the point to be made at a testing station.

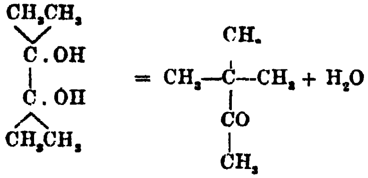
Pily *and* **Pily Bendy** (*Her.*) A shield divided pile wise, also with piles and bends; the latter term is then used. *See* PILE *and* HERALDRY.

Pin (*Carp. & Join.*) (1) A piece that fits into the socket of a dovetail. (2) A short wooden rod of small diameter, used in a variety of ways.

—— (*Eng.*) A general term for a small cylindrical piece of metal, especially one forming the fulcrum of a lever, or small fixed axle for a wheel or pulley.

Pinacoid (*Min.*) A crystal form which lies parallel to two of the axes of the crystal.

Pinacoline (*Chem.*) $CH_3.CC.C(CH_3)_3$. A colourless liquid; boils at 106°; smells like peppermint. On reduction it forms pinacolyl alcohol, $CH_3CHOH.C(CH_3)_3$, which is a liquid smelling like camphor; on oxidation it gives trimethylacetic acid, $(CH_3)_3C.COOH$. It is formed when pinacone is heated with dilute sulphuric acid—



Pinacone (*Chem.*)

$$\begin{array}{l}(CH_3)_2C.OH \\ \quad\;\; | \\ (CH_3)_2C.OH\end{array} \qquad \text{(Tetramethylglycol.)}$$

White crystalline solid; melts at 38°; boils at 172°; soluble in alcohol and in ether; dissolves in boiling water, and crystallises with $6H_2O$; the crystals melt at 42°. Heated with dilute sulphuric acid it loses one molecular proportion of water, and undergoes a remarkable intramolecular change to Pinacoline (*q.v.*) Pinacone is obtained by the reduction of acetone with sodium. *See* KETONES. Pinacone is the simplest member of a whole series of tetra-alkyl glycols, which are called by the general name Pinacones.

Pinacotheca. A picture gallery.

Pincers. In carpentry a tool provided with jaws for gripping the head of a nail which it is desired to withdraw from wood. Also applied in other trades to tools, constructed on a similar principle, used for gripping different objects.

Pinch Bar (*Eng.*) A crow bar.

Pinchbeck. An alloy of copper, zinc, and tin, something like gold in appearance. Formerly used in the manufacture of cheap jewellery. Named after the inventor, Christopher Pinchbeck.

Pinched Post (*Paper*). A sheet of drawing or writing paper measuring 18½ by 14¾ inches.

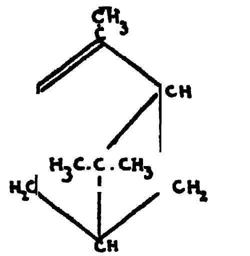
Pin Cop (*Cotton Spinning*). *See* COP.

Pin Drill (*Eng, etc.*) A drill or bit having a small cylindrical projection in the centre of its cutting end, which serves as a guide when a small hole (into which the pin fits) is being drilled out to a larger size.

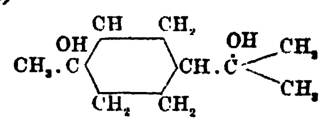
Pine. *See* WOODS.

Pineapple (*Botany*). The well known fruit of the tropical plant *Ananas sativus* (order, *Bromeliaceæ*) consists of a succulent mass formed by the coalescence of the fruits of a mass of flowers.

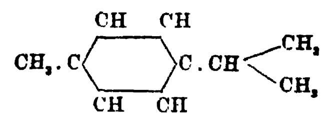
Pinene (*Chem.*) (A Terpene.)



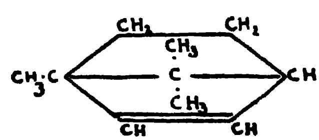
A colourless liquid; boils at 155°; volatile in steam; smells like turpentine; it is known in a dextrorotatory (45°), a lævorotatory, and an optically inactive form; insoluble in water; soluble in ordinary organic solvents. It has a very large number of reactions which are important in the chemistry of the terpenes (*q.v.*) A few are: (1) It adds one molecular proportion of bromine, forming a *dibromide*; it adds a like amount of hydrogen chloride, forming a *hydrochloride* (artificial camphor); it adds a like amount of nitrosyl chloride, forming *pinene nitrosochloride*; it adds twice the amount of hypochlorous acid, forming a dichlorhydrin with splitting of the bridged ring; it adds two molecules of water under the influence of dilute sulphuric or nitric acids, forming *terpin hydrate*, which has been synthesised and shown to have the constitution (*see* TERPENES)



When the dibromide is heated, it gives cymene; pinene itself on heating with iodine also gives cymene—

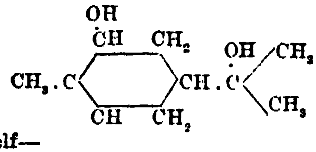


When the hydrochloride is heated with sodium acetate and acetic acid at 200°, it does not yield pinene again, but an isomeric terpene called camphene.

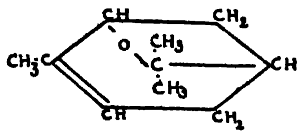


The hydrochloride from dextropinene is inactive; that from lævopinene is lævorotatory. The nitrosochloride, on heating with alcoholic potash, loses hydrochloric acid and forms nitrosopinene, which can be reduced to an amine, and the pinylamine hydrochloride on heating gives a good yield of cymene. The nitrosochloride is important as a means of identifying pinene; for this purpose it is prepared by acting on the pinene with glacial acetic acid, ethyl nitrite, and hydrochloric acid in the cold: the nitrosochloride crystallises out. (2) A very large amount of work has been done on the oxidation

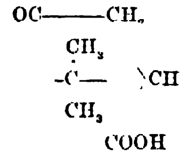
products of pinene. It is oxidised in air under the influence of sunlight to pinol hydrate.



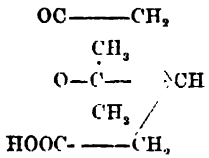
Pinol itself—



is always formed in small quantity in addition to the nitrosochloride, when nitrosylchloride acts upon pinene. When pinene is oxidised with nitric acid it yields terephthalic acid (*q.v.*) and terebic acid—



The same acid is formed when pinol is oxidised with nitric acid or with permanganate. When pinene is oxidised with chromic acid it yields terpenylic acid:



The same acid is formed when pinol hydrate is oxidised with potassium permanganate. Both terebic and terpenylic acids have been synthesised. It will be seen that every reaction is in harmony with the formula given for pinene, so that although pinene has not been synthesised its formula may be regarded as established. Pinene is the principal constituent of turpentine, and the dextropinene occurs in American and Burmese turpentine, and the lævopinene in French turpentine. Pinene also occurs in many other essential oils, *e.g.* those of rosemary, pine, juniper, camphor, laurel, lavender, mace, parsley, sage, etc It can be obtained from terpentine by distillation.

Pinholing (*Dec.*) This defect in varnished work is only found on the best class of work, which has been rubbed down with felt and powdered pumice-stone, and is due to the ground pumice not having been properly washed off.

Pinion (*Eng., etc.*) A small toothed wheel. The term does not denote any particular size or form of wheel.

Pin Mark (*Typog.*) A small circular indentation on the side of a type, made in the process of casting by a small pin in the mould. *See* TYPEFOUNDING.

Pinnacle (*Architect.*) A feature which frequently forms the termination of a buttress in Gothic architecture. It was used with the object of adding weight to the buttress, thus assisting the latter in resisting thrusts. It generally consists of a shaft terminating in a small spire. *See* FLYING BUTTRESS.

Pinny (*Met.*) Metal containing spicules or small fragments of metal, harder than the rest, is said to be "pinny."

Pint. *See* WEIGHTS AND MEASURES.

Pinus (*Botany*). A large and important genus of *Coniferæ*, yielding timber, resin, turpentine, tar, and other products.

Pinxit. This Latin word, or the abbreviation *pinx.*, following the name of an individual on a painting or engraving, indicates that such person is the painter. The Latin word *sculpsit*, or the abbreviation *sculp.*, indicates the engraver.

Pipe Bending (*Eng., etc.*) In bending pipes of soft or malleable metal the cavity is first filled with sand, resin, fusible metal, etc., or by driving a bobbin or follower into the bore; the pipe is then bent by hammering or by the direct application of force in some convenient way. The material in the bore prevents a collapse of the pipe at the bend; it is removed when the bending is completed.

Pipeclay. Kaolin or china clay (*q.v.*). It is used in forming both moulds and patterns in some kinds of castings, and for very many economic purposes, *e.g.* cleaning or whitening soldiers' belts, gloves, etc.

Pipe Cutter (*Eng., etc.*) A tool consisting of a bar bent into a hook which grasps the pipe, and a sharp-edged disc of hardened steel which travels round the outside of the pipe. By applying considerable pressure this steel disc cuts into the metal.

Pipe Moulding. Cast iron pipes are usually made in considerable quantities at a time; the smaller sizes are moulded from an iron pattern, the larger ones are struck (*q.v.*) The mould is commonly vertical.

Pipe, Organ. *See* MUSICAL INSTRUMENTS.

Pipe Ovens *or* **Stoves** (*Met.*) A series of pipes enclosed in a chamber or oven heated by a fire or by furnace gases; air is driven through the pipes to become heated before being supplied to a blast furnace worked with a hot blast.

Piperaceæ (*Botany*). A lowly order of Dicotyledons of economic interest, as the genus *Piper* supplies the condiment pepper and Cubebs and Matico. The Betel leaf used in Areca nut chewing is derived from *Piper betle*.

Piperazine (*Chem.*) $NH\left<\begin{matrix}CH_2-CH_2\\CH_2-CH_2\end{matrix}\right>NH$

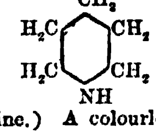
White crystalline solid (tables); melts at 104°; boils at 145°; soluble in water; its solution is a good solvent for uric acid, and is used in medicine, but its value is doubtful; powerful alkali; obtained by heating ethylene diamine hydrochloride, or by heating aniline with ethylene dibromide, forming the nitroso-compound of the product of this reaction, and boiling the nitroso-compound with alcoholic potash—

$$2C_6H_5NH_2 + 2C_2H_4Br_2 = C_6H_5N\left<\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}\right>NC_6H_5 +$$

$$4HBr \rightarrow ON.C_6H_4N\left<\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}\right>N.C_6H_4NO \rightarrow$$

$$HN\left<\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}\right>NH$$

Piperidine (*Chem.*)



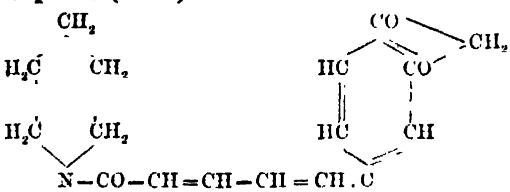
(Hexahydropyridine.) A colourless liquid; boils at

106°; smells like ammonia and pepper; soluble in water; powerful base, forming salts; it is a secondary base, for it yields a nitroso-compound with nitrous acid, and gives methyl piperidine with methyl iodide. Not attacked by boiling concentrated nitric acid; heated with concentrated sulphuric acid, it yields pyridine. It is prepared from piperine (*q.v.*) by boiling with alcoholic potash; also from pyridine by reduction with alcohol and sodium amalgam; also by heating pentamethylenediamine (*see* CADAVERINE) hydrochloride

$$CH_2 \begin{matrix} \diagup CH_2 - CH_2NH_2HCl \\ \diagdown CH_2 - CH_2NH_2HCl \end{matrix} =$$

$$CH_2 \begin{matrix} \diagup CH_2 - CH_2 \diagdown \\ \diagdown CH_2 - CH_2 \diagup \end{matrix} NH . HCl + NH_4Cl$$

Piperine (*Chem.*)



(an alkaloid). A white crystalline solid (prisms); melts at 129°; insoluble in water, soluble in alcohol and ether; it is a very weak base; with concentrated sulphuric acid it gives a blood-red coloration which vanishes on addition of water (test). Boiled for twenty-four hours with alcoholic potash, it is resolved into piperidine (*q.v.*), which can be distilled off, and piperic acid. Piperine can be reproduced from these by making the chloride of piperic acid and allowing this to act on piperidine in solution in benzene. When piperic acid is oxidised it yields piperonal (*q.v.*), and the acid can be synthesised from piperonal thus: Piperonal is carefully heated with aldehyde and dilute caustic soda—

$$C_6H_3 \begin{matrix} \diagup O_2CH_2 \\ \diagdown C \overset{\diagup H}{\underset{\diagdown O}{}} \end{matrix} + CH_3 . CHO =$$

$$C_6H_3 \begin{matrix} \diagup O_2CH_2 \\ \diagdown CH : CH . CHO \end{matrix} + H_2O$$

Piperonyl Acrolein.

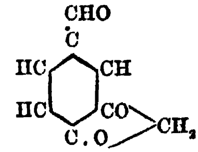
This aldehyde undergoes Perkin's reaction (*q.v.*) with acetic anhydride and sodium acetate—

$$C_6H_3 \begin{matrix} \diagup O_2CH_2 \\ \diagdown CH : CH . CHO \end{matrix} + CH_3COOH =$$

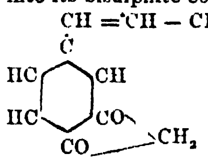
$$C_6H_3 \begin{matrix} \diagup O_2CH_2 \\ \diagdown CH : CH - CH : CH - COOH \end{matrix} + H_2O.$$

The product is piperic acid. Thus piperine is an alkaloid which can be completely synthesised. Piperine occurs in black pepper, white pepper, long pepper to the extent of 8 to 9 per cent. It is obtained from the ground white pepper by mixing it with slaked lime and water, boiling for 15 minutes, and evaporating to dryness on the water bath. The dry powder is extracted with ether, and the crude alkaloid crystallises out on concentrating the ethereal solution. It is recrystallised from alcohol till pure.

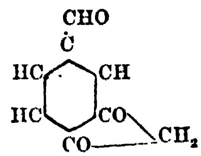
Piperonal (*Chem.*)



(Protocatechuicaldehyde methylene ether). Also called Heliotropine, because it smells like heliotrope. A white crystalline solid (prisms); melts at 37°; soluble in alcohol, ether, hot water. Its chemical behaviour is that of an aldehyde, *e.g.* it gives piperonylic acid, $CH_2O_2C_6H_3COOH$, on oxidation; piperonyl alcohol, $CH_2O_2C_6H_3CH_2OH$, among other products, on reduction; and it yields an oxime which melts at 110°. It is formed from protocatechuic aldehyde and methylene iodide by the action of an alkali: it is also formed by the oxidation of piperic acid (*see* PIPERINE) by potassium permanganate. In quantity for use as a perfume it is prepared from isosafrol. *See* SAFROL. The isosafrol is oxidised by potassium dichromate and dilute sulphuric acid, the product distilled in steam, the distillate extracted with ether, and the piperonal purified by conversion into its bisulphite compound.



Isosafrol.



Piperonal.

Pipe Sleekers (*Moulding*). Tools used in smoothing the interior of moulds for pipes, etc.

Pipe Tap (*Eng., etc.*) A screw tap (*q.v.*) for cutting gas threads; often termed a GAS TAP.

Pipe Tongs (*Eng., etc.*) Tongs with jaws adapted to holding and screwing up wrought iron pipe or barrel. The inner surface of the jaws is curved to fit the pipe, and furnished with grooves or serrations to secure a firm grip.

Piqué (*Textile Manufac.*) A cloth with ribs or welts running from selvedge to selvedge, produced by the insertion of thick weft or wadding between a fine face cloth and the back warp.

Pirameter. An instrument for measuring the amount of draught resistance of a road to a vehicle.

Pirl Finish (*Woollen and Worsted Manufac.*) A style of finish applied to fine cloths of a Venetian type in which clearness and brightness are the chief characteristics.

Pirn (*Cotton Manufac.*) A bobbin, tube, or quill used for winding weft yarn on to, so as to fit into the shuttle.

—— *or* **Quill** (*Silk Manufac.*) A hollow bobbin carried in shuttle on which the weft is wound.

Piscina (*Architect.*) A shallow basin placed in a niche near the altar in a church. A pipe is carried from the basin to the exterior of the building, the piscina being intended to receive the water used by the priest for washing his hands and rinsing the chalice used in the Communion Service.

Pisolite (*Geol.*) A coarse variety of oolite (*q.v.*) with the separate grains, in many cases, as large as peas. Like normal oolite, this type seems to be, in nearly all cases, due to deposition around a nucleus of successive layers of carbonate of lime secreted and left by an alga.

Piston (*Eng.*) In general a movable partition fitting closely into the bore of a hollow cylinder. The piston of a steam engine is a disc, firmly attached to the piston rod, and provided with grooves on its circumference into which are fitted piston rings (*q.v.*) or some other form of steam-tight packing. In gas and petrol engines the piston is usually a tubular casting closed at one end, and the connecting rod is attached to the piston without any intermediate piston rod. *See* GAS ENGINE, *etc.*

—— (*Music*). A valve used in brass instruments, enabling the tube to be lengthened, and lowering the pitch of the sound. *See* VALVE HORN, p. 435.

Piston Packing (*Eng.*) The material placed round a piston to make a steam-tight or an air-tight fit.

Piston Ring (*Eng.*) One of the metal rings fitted on a piston to make it steam tight. They are turned to a diameter slightly larger than that of the cylinder, and are then cut across and opened out sufficiently to enable them to be passed over the piston till they fall into one of the grooves cut on the periphery of the piston. When the piston is put in place the rings press closely against the bore of the cylinder. The joints or cuts in the rings should be arranged so that they do not come opposite to each other, in order that the possibility of leakage may be reduced to a minimum.

Piston Rod (*Eng.*) The cylindrical rod which communicates the motion of the piston to the connecting rod.

Piston Rod Gland (*Eng.*) The short tube which fits into the stuffing box (*q.v.*) in the cylinder cover, and presses the packing against the piston rod in order to make a steam-tight joint.

Piston Spring (*Eng.*) A piston ring (*q.v.*), or in some cases a steel spring placed in the groove round the piston to press the ring outward against the cylinder.

Piston Valve (*Eng.*) A valve consisting of a small piston and cylinder; in the side of the latter are the openings, which are opened and closed by the movement of the piston past them. Piston valves are occasionally used in steam engines instead of the ordinary Slide Valve (*q.v.*)

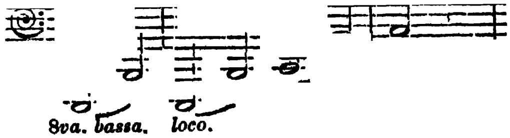
Pitch. The solid hydrocarbon residue left after the final distillation of certain organic substances, *e.g.* coal tar. It is used for caulking joints, etc., and occasionally as fuel. *See* GAS MANUFACTURE, PATENT FUEL, PETROLEUM, RESINS, *etc.*

——, **Burgundy** (*Botany*). A resinous exudation from the stem of the spruce fir, *Picea excelsa* (order, *Coniferæ*). The chief supply comes from Austria, Baden, and Switzerland. It resembles colophony, and is used medicinally for making plasters.

——, **Coal Tar** (*Dec.*) This is sometimes used instead of Volges pitch as a substitute for natural asphaltum. It is obtained by distillation of coal tar, and is of two kinds—soft pitch and hard pitch. The latter is too brittle for ordinary use. Soft pitch is thinned down with naphtha for varnish makers' use. It is also used to mix with coal dust to make briquettes.

Pitch (*Build., Eng., etc.*) (1) The angle of inclination of a roof, a flight of stairs, etc. (2) The distance between the centres of a number of holes, bolts, rivets, etc. (3) The distance a screw-thread advances in a single turn, measured along a line parallel to the axis. (4) The distance between the centres of wheel teeth, measured on the pitch-line.

Pitch (*Music*). The acuteness or gravity of a sound, determined by the rapidity with which the vibrations follow one another. The nomenclature of the different octave pitches is



CCC to BBB. Triple Great or 32 ft. 8ve. *CCCC to BBBB.*	CC to BB. Double Great or 16 ft. 8ve. *CCC to BBB.*	C to B. Great or 8 ft. 8ve. *CC to BB.*	c to b. Small or 4 ft. 8ve. *C to B.*

c^1 to b^1 once marked or 2 ft. 8ve. *c to b.*	c^2 to b^2 twice marked or 1 ft. 8ve. *c^1 to b^1.*	c^3 to b^3 thrice marked or 6 in. 8ve. *c^2 to b^2.*	c^4 to b^4 four times marked or 3 in. 8ve. *c^3 to b^3.*

In organ nomenclature, however, it is usual to talk of these octaves differently, as shown in the lower line of italics above. The standard of pitch in England unfortunately varies considerably. The two recognised pitches in use at the present time (1905) are the following: (1) The Old Philharmonic or high concert pitch, A,  = 455, and C,  540 double vibrations per second at 68° Fahrenheit. This pitch was introduced into England at the old Italian Opera, and adopted as the Kneller Hall or military pitch. Feeling is strongly against this extremely high pitch, which is 34 double vibrations per second more for A than in Handel's time; but unfortunately, partly because of the expense of providing new instruments for the bands, and partly because of an idea that more brilliancy is obtained with a high pitch, the retention of this high pitch is persisted in by military bands. (2) The other recognised pitch is the New Philharmonic, or Diapason Normal, A = 439 and C = 522 double vibrations per second. This pitch has been adopted not only by the Philharmonic Society, but also by the Royal Academy of Music, the Royal College of Music, the Guildhall School of Music, the Queen's Hall Orchestra, the Italian Opera, etc. The orchestral instruments are tuned to the French diapason normal A = 435, it being found that as soon as the instruments warm up the pitch rises four vibrations to A = 439; therefore, to meet this natural sharpening, the organ and pianoforte (the steel strings of this latter instrument having so great a tension—*see* PIANOFORTE, p. 430—are unaffected by the temperature of the building during a concert) are tuned to A = 439, as otherwise these instruments would soon be out of tune with the orchestra. Besides these two recognised pitches, there is the Medium, A = 446, and C = 530. In

England pianoforte tuning is done from a C tuning fork, the A tuning fork being more useful for orchestral and other stringed instruments.—W. W.

Pitch (*Typog.*) A line, imaginary or real, drawn across the coffin or bed of a printing machine to indicate the place at which contact is first made when the forme passes beneath the cylinder. The distance from the edge of the bed may be measured by a gauge.

Pitchblende (*Min.*) A complex uranate of uranyl, lead, and other metals, usually thorium, often metals of the lanthanum and yttrium groups, and containing traces of radium. Cubic, the crystallised varieties being known as Uranniobite, Bröggerite, Cleveite, and Nivenite. The crystallised varieties are rare. The commoner massive variety is of a dull grey black colour, and has a peculiar pitchlike lustre. Its density is high—the massive variety about 6·4 and the crystallised variety as high as 9·7. It contains 70 to 80 per cent. of the oxides of uranium, with about 10 per cent. of lead, 5 per cent. silica, and 3 per cent. ferrous oxide, besides traces of many other elements. Also known as Uraninite. It is found in several mines in Cornwall; abroad at Kongsberg in Norway, Marienburg, Schneeberg, Johanngeorgenstadt, and Wiesenthal in Saxony, Joachimstal and Przibram in Bohemia, Retzbanya in Hungary, Adrianople in Turkey, Middletown and Haddam in Connecticut, etc. In Bohemia uranate of sodium is made from it. The oxide of uranium prepared from it is used to give the well known opalescent green colour to glass. As a porcelain pigment the oxide gives a yellow tint in the enamelling furnace and a black colour in the baking furnace. The mineral is now of great interest as the chief source of radium.

Pitchboard (*Carp. and Join.*) A triangular shaped piece of board, used for setting out stairs.

Pitch Chain (*Eng.*) A metal chain, such as that used in cycles for transmitting motion from one toothed wheel to another.

Pitch Circle (*Eng.*) Two ordinary toothed wheels gearing with one another may be replaced in theory by two circles rolling in contact, termed the Pitch Circles; the ratio of the diameters of these two circles is inversely as the angular velocities of the two gear wheels. *See also* WHEEL TEETH.

Pitch Cone (*Eng.*) A pair of bevel wheels can be replaced in theory by a pair of cones rolling in contact with each other, the axes of the cones intersecting and coinciding with the axes of the bevel wheels. These cones are the pitch cones of the two wheels.

Pitcher. A granite set. A small paving stone.

Pitching Pieces (*Build.*) The carriage pieces supporting winding stairs.

Pitch Line (*Eng.*) In the case of a toothed rack, the pitch circle (*q.v.*) becomes a straight line, which may be termed the PITCH LINE. The name is, however, often used for the pitch circle of an ordinary wheel.

Pitch of Chains (*Cycles, etc.*) The distance between the centres of two successive pins in a chain.

Pitch of Poles, Windings, etc. (*Elect. Eng.*) The distance between the centres of poles, armature conductors, etc., measured along the pitch line.

Pitch of Wheels (*Eng.*) The distance from the centre of one tooth to the centre of the next.

Pitchpipe (*Music*). A small reed pipe made of metal which sounds the different notes of the scale when the wind is drawn through by the mouth, according to the length of the vibrating portion. The lengths are marked off at the end. It is known as Eardley's chromatic pitchpipe.

Pitchstone (*Geol.*) An eruptive rock with a resinous fracture and lustre, usually of sub-acid or even of sub-basic composition, which has cooled from the molten state under but little pressure and at a comparatively rapid rate. Hence it has passed direct into a sub-vitreous state. Most, if not all, pitchstones occur as Trappean rocks. One of the best known examples is the Pitchstone of Corriegills, Arran, in which the microscope reveals structures of great interest. Another forms the Scuir of Eigg, which may also be intrusive.

Pit Head Gear (*Mining*). The supports of the winding gear (*q.v.*) over the mouth of a shaft.

Pitman (*Eng.*) A CONNECTING ROD (*q.v.*)

Pit Sand (*Build.*) Sand that is dug out of a pit, as distinguished from sea and river sand.

Pit Saw (*Carp., etc.*) A long saw worked by two men, one standing above the wood, the other below, in a pit, termed a SAW PIT. The pit saw is now superseded by saws worked by power.

Pitting (*Dec.*) A defect in varnish which on drying shows small holes over its surface. It is caused by a greasy, damp, or oily surface, or it is caused by applying an elastic varnish over a hard and unyielding ground. Resin varnishes of low grade not infrequently exhibit this defect.

—— (*Eng.*) A common form of corrosion in boilers. It is not peculiar to any special part, except in locomotives, where the largest ring and bottom of the barrel suffer most. Feed water heaters suffer chiefly at the cold water inlet. It takes the form of cones or spherical depressions filled with a yellowish, dusty deposit, consisting mainly of ferric oxide and some organic matter, with mineral salts. The powder forms a blister above the pit, having a thin skin. The skin is chiefly calcium carbonate, ferrous oxide, gypsum, and magnesium carbonate. Bad circulation, very soft, lime free water, and condensation in the upper part of the steam space, when one boiler in a battery is kept standing for long, seem to be the chief causes.

Piu (*Music*). More; as *piu mosso*, more movement, quicker. *Piu forte*, louder: abb. *p.f.*

Pivot. A point, centre, or fulcrum, on which a related part turns or oscillates.

—— (*Clocks and Watches*). The reduced cylindrical end of a small shaft or "arbor": the part that works in the bearing.

Pizzicato (*Music*). A direction used in stringed instrument music to denote that the strings are to be plucked with the finger instead of being bowed.

Place Bricks (*Build.*) Underburnt, soft bricks, only used for inside walls that have to be plastered.

Placer (*Mining*). (1) Gold diggings in general, *i.e.* where surface deposits are washed for gold, etc. (2) Mining by means of a jet of water under pressure

(hydraulic mining), by which loose earth, etc., is washed away, is often termed Placer Mining.

Placer (*Pottery*). A person whose duty it is to place the various wares in their right positions in their respective ovens.

Plagal (*Music*). *See* MODES.

Plagal Cadence (*Music*). *See* CADENCE.

Plagioclase (*Geol.*) A convenient general term employed for all the felspars except Orthoclase, as all but this one cleave at such angles that no two of the adjacent cleavage faces are at right angles to each other. The two chief Plagioclase felspars are the Soda felspar Albite and the Lime felspar Anorthite. Native mixtures of these, in various proportions, constitute a number of intermediate types, of which the Soda Lime felspar Oligoclase and the Lime Soda felspar Labradorite are geologically the most important.

Plain (*Lace Manufac.*) Yarn that has not been "gassed."

Plain Song (*Music*). It is the special music used officially in the Church services, and is so called to distinguish it from measured and figured music. The music is written on four-lined staves with either the (F) or (C) clefs placed on the most convenient line according to the compass of the melody, which usually does not exceed an octave. The notation consists of three shapes, the , the , and the . These have always been known as the long, the breve, and the semibreve; but the investigations of the Solesmes Fathers show that these different shapes are the result of different plain song writing, and do not express difference of time value. It is shown that diamond shaped notes occur in well written manuscripts in descending passages only, and Spanish manuscripts have diamond shaped notes instead of square ones throughout, whilst a tail is added to every *single* note. These notes are used in combination to form certain figures called neums. The plain song melodies are formed from certain scales called modes (*q.v.*), the only accidental allowed being the B flat, and this in order to avoid the interval of the tritone. *See also* MODES *and* NOTES.

Plain Tile (*Build.*) A flat roofing tile, with or without nibs at the back for fixing.

Plain Weave (*Cotton Manufac.*) *See under* LOOM (figs. 2 and 3).

Plan. (1) The view of an object as seen from above. (2) Commonly used for a SECTIONAL PLAN; that is, the intersection of any object, *e.g.* a building with a horizontal plane. If this plane coincide with the level of ground, we get a GROUND PLAN; but drawings showing the outline of different floors are also termed plans.

Planchet (*Coins*). A flat smooth strip of metal from which coins are struck.

Plane. A flat surface, *i.e.* one in which a straight line lying entirely in the surface may be drawn in any direction. The last condition should be noted, for straight lines may be drawn on the surfaces of cylinders, cones, etc., but they cannot be drawn in any direction.

—— *See* WOODS.

Plane, Plane Iron (*Carp.*) *See* PLANES.

Plane of the Ecliptic (*Astron.*) The plane in which the Earth moves round the sun.

Plane of Twinning (*Min.*) *See* TWIN PLANE.

Planer (*Typog.*) A rectangular flat piece of wood with a smooth surface, and generally grooved on the longer edges. Used in conjunction with the mallet for levelling type before it is locked up in the chase.

—— (*Eng.*) *See* PLANING MACHINE.

Planes (*Carp. and Join.*) Planes used in the woodworking trades may be divided into three main classes, according to the nature of the surfaces which they are required to produce, as follows: (1) Planes used in producing plane surfaces of indefinite width, *e.g.* JACK, TRYING, JOINTING, and SMOOTHING PLANES (*q.v.*) (2) Planes for forming plane surfaces of definite and usually small width, *e.g.* RABBET PLANES, PLOUGHS, MATCH PLANES, etc. (3) Planes used for forming curved surfaces, such as ROUNDS and HOLLOWS, MOULDING and BEADING PLANES, COMPASS PLANES, *etc.*

The simple planes in Class 1 are described separately. Those in Class 2 have a narrow iron, the cutting edge of which extends to the extreme outer edge of the body or stock. They are in most cases provided with a FENCE or guide, which is pressed against the edge of the piece of wood which is being worked, and causes the plane to travel parallel to this edge. A RABBET or REBATE PLANE has a cutting iron from ½ to 1½ in. or more in width, and is used for forming a rabbet (*q.v.*) along the edge of a piece of wood. The best forms have a fence. A PLOUGH has a set of irons, from ⅛ in. in width upward; it is used for cutting grooves of various depths and at various distances from the edge of the wood. A vertical stop or fence is fitted to regulate the depth of the groove. A SHOULDER PLANE resembles a rabbet plane in form, but has no fence; the body is usually made partly or entirely of metal, and the cutting iron is set at a very acute angle. It is used in cutting across the grain in finishing off the shoulders of tenons. MATCH or MATCHING PLANES are made in pairs, with irons suitably shaped for forming tongues and grooves, etc., for joining two boards edge to edge.

Planes contained in Class 3 vary very much in the form of the cutting iron, but otherwise are very similar in pattern; they are usually without a fence when made of wood, though the American patterns usually possess one. HOLLOWS and ROUNDS are planes with cutting irons whose edge is an arc of a circle; they are made in pairs, one being concave, the other convex. BEADING PLANES have the cutting edge so shaped as to cut beads of different forms, the sole of each plane being so shaped as to fit exactly to a piece of the finished beading. COMPASS PLANES, VIOLIN MAKERS' PLANES, etc., have a curved sole and cutting edge, and are used in producing various concave and convex surfaces.

All the above planes may be made either of wood or iron; the latter have not come into common use in England, though they possess many advantages. Among these are the freedom from wear, absence of warping and cracking, etc., which prevent the plane from losing its correct shape; the better method of fixing the iron and of adjusting its exact position; the very convenient fences, etc. There are also various forms of iron plane which cannot be made in wood at all, such as a SIDE RABBET PLANE, used for planing the sides of a narrow groove, and a

CIRCULAR PLANE with a flexible steel sole, which can be bent into an arc of a circle, either convex or concave. The radius of this circle can be varied within very wide limits, and the plane used for finishing off circular work, such as carriage wheels.

Planes of Symmetry (*Min.*) Imaginary planes dividing crystals into halves which are symmetrical to one another. The cubic system has nine possible planes of symmetry, the hexagonal division of the rhombohedral system has seven, the rhombohedral division of the same system has four, the tetragonal system has five, the orthorhombic system three, the monosymmetric system, as its name implies, has only one, and the triclinic system has none.

Plane Surface, Production of. (1) MECHANICAL METHOD: Three similar plates of iron are taken, each having a surface which has been rendered approximately plane by means of a planing machine and the ordinary processes of the workshop. One of these is then covered with a film of red lead and oil, and pressed against the second plate; the projecting portions of either plate cause a patch of red lead to be transferred from the first to the second plate, and these projecting portions are removed by scraping. By proceeding in this way it is possible to make the surface of the second plate an exact counterpart of that of the first. In the same way the third plate can also be made a counterpart of the first. If now the second and third plates be compared, they will not be an exact counterpart of each other unless the first was truly plane. By the comparison of the three, taken in pairs, they can ultimately be brought to the same form, which must be a plane surface. When once such a plane surface has been prepared, it may be used as a standard by which other surfaces may be rendered plane. *See* SURFACE PLATE. (2) OPTICAL METHOD: Lord Rayleigh's method of testing the form of a surface is to fix the plate in a vessel filled with water at such a depth that the surface is about ·5 mm. under the water. If the surface be viewed by monochromatic light, any irregularities of the surface are made visible by the production of interference patterns. The projecting portions are removed by grinding or rubbing, and the test repeated until the surface becomes sufficiently regular. The method is capable of producing a very high degree of accuracy.

Plane Table (*Surveying*). An instrument consisting of a drawing-board mounted on a tripod, and with arrangements to enable an observed angle to be laid down direct on a sheet of paper stretched upon it.

Planetary Nebulæ (*Astron.*) Nebulæ which shine with a planetary and often bluish light, and are circular or slightly elliptical in form.

Planets (*Astron.*) Bodies which revolve round the sun in closed orbits, comets excluded.

Planimeter (*Eng., etc.*) An instrument which enables the area of any figure to be measured by merely drawing a tracing point attached to a system of levers round the perimeter of the figure. When the tracing point has completed its path, the extent of the area is recorded on a graduated dial. It is much used for finding the areas of INDICATOR DIAGRAMS.

Planing Machine (*Carp., etc.*) Planing machines for wood are of two distinct types. (1) Those with a fixed plane iron projecting from an opening in a table, over which the wood is drawn by mechanism. (2) Machines with rapidly revolving cutters, which may revolve about a vertical or a horizontal axis.

Planing Machine (*Eng.*) The machine used for the production of large flat surfaces. The work is caused to move in a horizontal plane, so as to be acted on by a fixed cutting tool. The latter is held by mechanism resembling a SLIDE REST (*q.v.*), so that the length and breadth of each cut can be accurately regulated.

Planishing (*Eng., etc.*) Finishing off bright metal work by hammering the surface with a smooth hammer, which is in some cases driven by machinery so as to give a very great number of light blows in a minute.

Plank. A piece of timber over 9 in. wide, generally 11 in., and from 2 in. to 4 in. thick.

Plant (*Eng., etc.*) The collection of machines and other appliances used in any particular workshop, factory, trade, etc.

Plantain (*Botany*). Like the banana, the plantain, *Musa sapientum*, var. *Paradisiaca* (*Musaceæ*), is a native of tropical climates. The plant sometimes reaches a height of 20 feet; the fruit is used as a food, and the fibres of the stem yield valuable material for cordage and paper.

Planted Moulding (*Carp. and Join.*) Moulding prepared from a separate piece of wood and fixed to any piece of joinery. *Cf.* STUCK MOULDING.

Planté's Secondary Battery (*Elect.*) *See* ACCUMULATORS.

Plaque. A decorative piece of terracotta, metal, or other material, shaped like a plate and bearing some ornamental design suited to the material upon which it is executed.

Plasma (*Min.*) A semi-translucent pale green variety of Chalcedony.

Plaster. A mixture of lime and sand. *See* CEMENTS.

Plaster Cast. *See* CAST.

Plaster, Fibrous (*Dec.*) Moulded ornaments made of plaster on a canvas backing, and used for the embellishment of ceilings, walls, etc.

Plaster of Paris. *See* CEMENTS *and* CALCIUM COMPOUNDS.

—— **Painting on** (*Dec.*) In painting with oil paint on plaster made from either Keen's or Parian cement, the paint may be applied within twenty-four hours of the plaster being executed. If, however, plaster of Paris is used, several days must be allowed to elapse. The surface having been rubbed down with sandpaper, the first coat, mixed somewhat thin, may then be applied. After twenty-four hours a second coat may be given, and this should be mixed with rather more oil than the first. Imperfections should be stopped with hard lead stopping, and after another day a third coat may be given, and after a similar interval a fourth coat. It is usual to finish the surface of a painted wall "flat," *i.e.* without gloss, and to stipple the work (*see* STIPPLING) by means of a specially made brush, which is dabbed against the paint while wet, in order to produce an uneven surface.

Plastic (*Arts*). The term applied to substances that are capable of being easily moulded or fashioned into various forms, *e.g.* clay, wax, etc.; appertaining to sculpture and the allied arts.

Plastic Clay (*Geol.*) As the name of a geological formation this is synonymous with the Reading Beds, a local type of development of the middle members of the Lower London Tertiaries. The type prevails not only near the town of Reading, but as far down the Thames Valley as Erith, and also in the Isle of Wight and adjacent parts of the South of England.

Plastic Sulphur (*Chem.*) *See* SULPHUR.

Platanus (*Botany*). A genus of the *Platanaceæ*, a Dicotyledon order. The timber of the Plane (*P. orientalis*) and Buttonwood (*P. occidentalis*) are useful woods.

Platband (*Architect.*) (1) A fascia or band, of small projection. (2) A lintel to a door or window is sometimes referred to as a Plat-band.

Plate. (1) Sheet metal. (2) Silver or gold vessels, cutlery, etc. (3) Electroplated ware. *See* ELECTROPLATING. (4) The term plate is frequently applied to some special portion of a machine or structure, *e.g.* FISH PLATE, etc.

—— (*Engrav., etc.*) A flat sheet of metal upon which some subject is engraved in order that impressions may be obtained. The term is sometimes applied to the printed impression and to illustrations appearing in books. A page of stereotype (*q.v.*)

Plate Armour. *See* ARMOUR.

Plate Columns (*Chem. Eng.*) A special form of reaction tower (such as the Lunge-Rohrmann type, etc.) used in modern methods of vitriol manufacture.

Plate Dowels (*Pattern Making*). Metal dowels used to connect two parts of a pattern which have to be taken apart for withdrawal from the mould.

Plate Edge Planing Machine (*Eng.*) A machine used for planing the edges of large plates used for making girders, etc. The sheet of metal is fixed, and the cutting tool travels along it.

Plate Furnace (*Eng.*) A form of reverberatory furnace used for heating large plates which have to be shaped for boiler work, etc.

Plate Gauge (*Eng.*) (1) Gauges consisting of flat plates used as standards of thickness. (2) Gauges with notches of known width used for gauging the thickness of plates. *See also* WIRE GAUGES.

Plate Girders (*Eng.*) Girders consisting of one large plate forming a WEB (*q.v.*) and having flanges riveted at the top and bottom.

Plate Glass. This is used chiefly for mirrors, large windows, shop fronts, etc. Before being polished it is termed ROUGH PLATE, and is translucent rather than transparent. To be made into polished plate, both sides are ground flat, smoothed and polished. The method of manufacture admits of very large sheets of plate being made. Rough plate is used for lighting, *e.g.* skylights, etc. *See* FURNACES *and* GLASS MANUFACTURE.

Plate Glazing (*Paper Manufac.*) Polishing paper by pressure. The paper is placed between copper sheets.

Plate Machine (*Elect.*) A machine for the production of charges of electricity by the friction between a flat disc or circular plate of glass and pads or rubbers; now little used.

Plate Mill (*Eng.*) A rolling mill with truly cylindrical rollers used for making sheet iron.

Plate Moulding (*Foundry*). Moulding (*q.v.*) in which the pattern is made in two halves, each half being attached to a flat plate on which the moulding box or flask (*q.v.*) is laid while being filled with sand.

Platen (*Eng.*) The flat table on which the material or work lies in planing machines, etc.

Platen Machine (*Print.*) *See* TYPOGRAPHY.

Plate Shearing Machine (*Eng.*) A shearing machine (*q.v.*) with very long cutting edges, for cutting large sheets of metal.

Plates, Iron (*Met.*) Iron plates range from a thickness 0·238 in. (No. 4 Birmingham Wire Gauge) upwards. Thicknesses below this are classified as "sheets." But the thin sheets used for tinning are called Block Plates, of which singles range from No. 4 to No. 20 B.W.G. (·238 to ·035 in.); doubles No. 20 to No. 25 B.W.G. (·035 to ·02 inch); and trebles No. 25 to No. 27 B.W.G. (·02 to ·016 in.)

Plate Tracery (*Architect.*) The form of tracery used in Early Gothic work. It consists of openings of various shapes cut through a flat slab of stone. *See* BAR TRACERY, FLAMBOYANT TRACERY, *and* TRACERY.

Plating. Covering the surface of an object (usually of metal) with a layer or coating of some more valuable metal. *See* ELECTROPLATING.

—— (*Eng.*) The marking, cutting, drilling, etc., of iron plates for boiler or girder work.

Platinoid (*Elect.*) An alloy resembling German silver, to which 1 or 2 per cent. of tungsten has been added. Used for resistance coils.

Platinotype (*Photo.*) A process of photographic printing in which the image is finally formed in platinum black. It is dependent upon the action of light on ferric oxalate, which it reduces to ferrous oxalate. The ferrous oxalate, when dissolved in a solution of potassium oxalate, instantly reduces the platinum from its chlorides and other salts.

Platinum (*Chem.*) Pt. Atomic weight, 195. A silvery white metal; melts about 2000°; specific gravity, 21·5; very malleable and ductile. When melted it dissolves oxygen, but gives it up again on cooling. The heated metal absorbs hydrogen, and a heated platinum tube allows hydrogen to pass through it. *See* OCCLUSION. Platinum causes the union of oxygen with many combustible gases and vapours; when the platinum is finely divided, that is presents a large surface, it can do this at the ordinary temperature; but ordinary platinum wire or foil requires to be warmed first. Thus a warm platinum wire will cause the union of oxygen and hydrogen to occur, and also the union of oxygen with vapour of methyl alcohol; *e.g.* if a warm platinum spiral be held over the surface of some methyl alcohol contained in a beaker, the wire will quickly become red-hot, and if the distance be carefully adjusted, will keep so, the alcohol being meanwhile oxidised to aldehyde. This property of platinum is applied in the construction of automatic gas lighters, and in the "poker" used in poker work, where the hot platinum causes the union of oxygen with the vapour of a hydrocarbon. *See also* SULPHUR TRIOXIDE *under* SULPHUR COMPOUNDS. Very finely divided platinum suspended in water displays properties closely analogous to those of enzymes. *See* ENZYMES, p. 205. Platinum is slowly oxidised on prolonged heating in oxygen; it is not dissolved by any acid.

A solution of potassium cyanide dissolves platinum, slowly in the cold, quickly on heating. Aqua Regia (*q.v.*) dissolves it, forming chloroplatinic acid, H_2PtCl_6. Chlorine converts it into platinum dichloride, $PtCl_2$, or tetrachloride, $PtCl_4$. *See* PLATINUM COMPOUNDS. Platinum is also attacked by fused caustic soda or potash, or salts of these metals, which liberate the oxides on being heated. Easily reducible metals form alloys with platinum, so that compounds of lead, zinc, and antimony should not be heated in platinum vessels. A platinum vessel is injured by heating it in a smoky flame, the carbon probably forming a carbide. Platinum always occurs uncombined in nature, but never pure; the ore contains iron, rhodium, gold, iridium, palladium, osmiridium, and copper. The ore is treated under slight pressure with diluted aqua regia, the clear solution evaporated to dryness, and gently heated to change the palladium and rhodium chlorides to less soluble lower chlorides. The mass is extracted with water, acidified with hydrochloric acid, and ammonium chloride added to precipitate the platinum as ammonium platinic chloride. The metal is obtained from this double chloride by heating it; when this double chloride is *gently* heated it leaves behind "spongy platinum," which is used in the catalytic reactions mentioned above; when the metal is to be cast it is melted in the oxyhydrogen flame. When platinum is required in a still more finely divided form—"platinum black"—the dichloride is warmed with alcoholic potash. For another form of finely divided platinum *see* ENZYMES, p. 205.

Besides the uses mentioned above for platinum it is largely used in making dishes and crucibles intended for use at a high temperature in chemical processes; and in Russia a platinum coinage was in circulation at one time. Platinum wire is used in making small incandescent electric lamps. *See also* PLATINUM COMPOUNDS. About 95 per cent. of the world's platinum comes from the Urals in Russia; the amount from Russia in 1902 was 7,306 kilograms.

Platinum (*Min.*) The native metal of the same name. Cubic, but usually in grains and nuggets up to 21 lb. troy. Colour, white; metallic lustre. Density, 16—19. The mineral contains traces of gold, iridium, rhodium, palladium, iron, osmium, and copper. The platinum varies from 45 to nearly 90 per cent. From the Urals in alluvial gravel, from which some forty tons are raised annually. From South America, Borneo, California, St. Domingo, New South Wales, etc.

Platinum Compounds (*Chem.*) OXIDES: *Platinous oxide*, PtO, is a grey powder obtained by heating platinous hydroxide at a low temperature. On heating, it decomposes into its elements; reducing agents easily convert it into the metal; it has acid properties. The platinous hydroxide is obtained as a black powder by boiling potassium chloroplatinite, K_2PtCl_4, with dilute caustic soda in the proportions of one molecule of the former to two of the latter. *Platinic oxide*, PtO_2, is a black powder which behaves both as a basic and an acid oxide; it is obtained by carefully heating platinic hydroxide. The latter is obtained by boiling a solution of platinic chloride with excess of caustic soda, and heating the precipitate with acetic acid to remove sodium. The white substance so obtained is dried at 100°, when it forms the yellow platinic hydroxide $Pt(OH)_4$. CHLORIDES: *Platinous chloride*, $PtCl_2$, is a greenish brown powder; insoluble in water; soluble in hydrochloric acid, forming chloroplatinous acid, H_2PtCl_4; decomposed on heating. It is obtained by heating finely divided platinum in dry chlorine at 240° to 250°, or by heating chloroplatinic acid at 300°. Platinous chloride unites with carbon monoxide when heated in this gas at 250°, forming three compounds, $PtCl_2CO$, $PtCl_2 2CO$, and $2PtCl_2 . 3CO$. All these compounds are decomposed by water forming hydrochloric acid, carbon dioxide, and platinum. *Platinic chloride*, $PtCl_4$: a yellow or brown crystalline solid; soluble in water; decomposed on heating. When silver nitrate is added to its solution, silver chloroplatinate is precipitated, and not silver chloride; but on warming, the chloroplatinate decomposes, giving silver chloride and a solution of platinic chloride. The aqueous solution is believed to contain the acid H_2PtCl_4O. Platinic chloride is obtained by heating the metal to a high temperature in dry chlorine, or when chloroplatinic acid is heated carefully in chlorine or hydrochloric acid gas; its crystalline hydrate, $PtCl_4 5H_2O$, may be obtained by evaporating the solution from the decomposition of silver chloroplatinate by heating it with water. *Chloroplatinic acid*, H_2PtCl_6, commonly called platinic chloride, is a reddish brown, deliquescent, crystalline solid obtained by dissolving platinum in aqua-regia and repeatedly evaporating with hydrochloric acid on the water bath to remove nitric acid. Its salts are important; the potassium and ammonium salts, K_2PtCl_6 and $(NH_4)_2PtCl_6$, crystallise alike in golden yellow crystals, and are sparingly soluble in water and less soluble in alcohol. Their formation is employed as a qualitative test for and as a means of quantitatively estimating potassium and ammonia. Organic ammonia derivatives behave like ammonium salts; *e.g.* $(C_6H_5NH_2 . H)_2PtCl_6$ is formed from aniline, $C_6H_5NH_2$. The potassium salt on heating gives potassium chloride and platinum; the ammonium salts leave only platinum behind. The sodium salt is very soluble in water. When potassium chloroplatinate is reduced by cuprous chloride, or when chloroplatinic acid is reduced by sulphurous acid, and caustic potash added till neutral *potassium chloroplatinite*, K_2PtCl_4, is formed, this salt is used along with ferric oxalate in photography in the preparation of platinotypes. PLATINOCYANIDES: These compounds are the cyanogen analogues of the chloroplatinites, and may be regarded as derived from platinocyanic acid, $H_2Pt(CN)_4$. This acid is prepared by decomposing its barium salt with its exact equivalent of dilute sulphuric acid, or its copper salt by sulphuretted hydrogen, filtering, and evaporating the solution. It forms crystals the colour of which depends on the amount of water of crystallisation they contain; *e.g.* $H_2Pt(CN)_4 5H_2O$ forms red prisms with blue reflex. Soluble in water and in alcohol; reacts acid to litmus, and decomposes carbonates; decomposes above 140° into platinous cyanide and hydrocyanic acid. *Potassium platinocyanide*, $K_2Pt(CN)_4 3H_2O$, forms yellow prisms, which appear blue when viewed in one direction; it effloresces in air; soluble in water; not decomposed at 600°. It is used in the preparation of other platinocyanides. It is obtained by heating platinum black with potassium ferrocyanide, extracting with water, filtering and crystallising; also by boiling platinum black with a concentrated solution of potassium cyanide; also by boiling ammonium chloroplatinate with caustic potash and a concentrated solution of potassium cyanide till all ammonia is driven off. *Barium platinocyanide*, $BaPt(CN)_4 4H_2O$, crystallises in rhombic prisms with a yellow colour with blue reflex, or a green colour, according to the way they are viewed;

sparingly soluble in cold water, fairly soluble in hot water. It becomes fluorescent (yellowish green) on exposure to ultra-violet light, to Röntgen rays, and to radioactive elements. It is used in making fluorescent screens for experiments on these forms of radiation, and it was by such a screen that Röntgen discovered his rays: "I was working with a Crooke's tube covered by a shield of black cardboard. A piece of barium platinocyanide paper lay on the bench there. I had been passing a current through the tube, and I noticed a peculiar black line across the paper." The black line would be a shadow cast by some object impervious to the rays. This salt is prepared by decomposing the copper salt by baryta water. The copper salt is prepared by precipitation of potassium platinocyanide by copper sulphate; it is also prepared by passing the vapour of hydrocyanic acid into hot water, in which platinous chloride and barium carbonate are suspended until carbon dioxide ceases to be evolved. MAGNESIUM PLATINOCYANIDE, $MgPt(CN)_4 7H_2O$: Crystallises in regular prisms, which exhibit a fine series of colours—red, dark red, green, blue, blue violet, according to the way in which they are viewed. Crystallised from aqueous alcohol, it gives crystals containing $6H_2O$, which are yellow with blue and green reflex. The heptahydrate loses $2H_2O$ at 40° and the resulting pentahydrate is blue; at 100° the dihydrate is formed, which is colourless. It can be prepared by the action of magnesia on platinocyanic acid, or by precipitation of a solution of the barium salt with magnesium sulphate. *Complex nitrites* of platinum are known, such as $K_2Pt(NO_2)_6$. COMPLEX AMMONIA COMPOUNDS: Very many compounds of this kind are known. They may be divided into two chief classes, *viz.* platinous and platinic compounds. In the former, one atom of platinum unites with four molecules or groups to form a complex radical, which may then act with a maximum valency of two. In the latter, one atom of platinum unites with six molecules or groups to form a complex radical, which may then act with a maximum valency of four. THE PLATINOUS COMPOUNDS: Taking as examples the ammonia and chlorine compounds, we have the following:

I. $\left\{ Pt(NH_3)_4 \right\} Cl_2 \rightarrow$ Tetrammine platinous chloride or Platodiammine chloride.

II. $\left\{ Pt{}^{Cl}_{(NH_3)_3} \right\} Cl$ Chlortriammine platinous chloride or Platochlormonodiammine chloride.

III. $\left\{ Pt{}^{Cl_2}_{(NH_3)_2} \right\}$ Platinum dichlordiammine or Platosammine chloride and Platosemidiammine chloride.

In these compounds isomerism can occur in Class III. only. To distinguish between the isomers when the first name is used, the one compound is called a cis-compound and the other a trans-compound. When the other names are used, the platosemidiammine is identical with the cis-arrangement, and the platosammine with the trans-arrangement. Besides ammonia and chlorine, a large number of other radicals can occur in these compounds, *e.g.* amines, pyridine, the sulphonic acid group SO_2OH, nitrate, sulphate groups, etc. It is clear when other groups besides ammonia and chlorine enter into these compounds, isomerism may occur with any of the classes. Examples of these compounds are *Magnus's Green Salt*, which is the platinous chloride compound of tetrammine platinous chloride, and has the formula $[Pt(NH_3)_4]Cl_2 . PtCl_2$. It is obtained by acting on a boiling solution of platinous chloride in hydrochloric acid with ammonia, and is insoluble in water and in hydrochloric acid. When Magnus's green salt is boiled with ammonia, it gives tetrammine platinous chloride, $\left\{ Pt(NH_3)_4 \right\} Cl_2$ (Reiset's first chloride). When this is heated at 250° or evaporated with concentrated hydrochloric acid, it yields the trans-platinum dichlordiammine or platosammine chloride, $\left\{ Pt{}^{Cl_2}_{(NH_3)_2} \right\}$ (Reiset's second chloride). The compound isomeric with this is obtained by the action of ammonia on potassium chloroplatinite; it is the cis-platinum dichlordiammine or platosemidiammine chloride. THE PLATINIC COMPOUNDS: Taking as examples the ammonia and chlorine compounds, we have:

I. $\left\{ Pt(NH_3)_6 \right\} Cl_4$ Hexammine platinic chloride.

II. $\left\{ Pt{}^{Cl_2}_{(NH_3)_4} \right\} Cl_2$ Tetramminechloroplatinic chloride or Platinchlorodiammine chloride.

III. $\left\{ Pt{}^{Cl_3}_{NH_3)_3} \right\} Cl$ Triamminechloroplatinic chloride or Platinchloromonodiammine chloride.

IV. $\left\{ Pt{}^{Cl_4}_{(NH_3)_2} \right\}$ Diammineplatinic chloride or Platinchloroammine or Platinchlorosemidiammine.

Isomerism has been observed in Class IV. Other radicals besides ammonia and chlorine can occur in these compounds. It is doubtful if representatives of Class I. are yet known. The platinic compounds are obtained by oxidation of the platinous compounds. In both the platinous and platinic compounds the elements or groups in the complex radical do not show their ordinary reactions. For example, the platinum is not precipitated by sulphuretted hydrogen; the ammonia is not liberated by boiling with caustic soda; the chlorine is not precipitated by silver nitrate. For an explanation of the structure of these compounds *see* WERNER'S THEORY.

Platinum Standard of Light. The intensity of illumination emitted normally by one square centimetre of platinum at its temperature of fusion. This standard is also termed the VIOLLE standard.

Platinum Temperature (*Phys.*) The temperature obtained by the measurement of the resistance of a platinum thermometer, assuming the increase of resistance to be simply proportional to the temperature. If R_{100} be the resistance at 100° C., R_0 the resistance at 0° C., and R the resistance at the unknown temperature, then the value of the latter on the platinum thermometer, *i.e.* the platinum temperature, is given by the equation

$$pt = 100 \frac{R - R_0}{R_{100} - R_0}$$

The difference between this temperature (pt) and the temperature t on the air thermometer scale is given by the equation

$$t - pt = \delta \left\{ \left(\frac{t}{100}\right)^2 - \frac{t}{100} \right\}$$

in which δ is a constant for the particular platinum thermometer used, and is found by means of an observation of a third known temperature, usually the boiling point of sulphur. *See* MEASUREMENT OF TEMPERATURE.

Platinum Thermometer (*Phys.*) *See* MEASUREMENT OF TEMPERATURE.

Play (*Eng., etc.*) (1) A limited amount of movement, regular or irregular, allowed on certain parts of a machine, etc. (2) Space for motion.

—— (*Mining*). A miner's term for a period of cessation from work with the object of limiting the working time or the output.

Play of Colour (*Min.*) The property of causing light transmitted through the mineral to break up, giving a colour effect; well seen in Opal. It is due to the refraction of the light ray in passing into the crystal from the air and out again.

Plectrum (*Music*). A small implement of tortoise-shell, ivory, or metal used for striking or picking the strings of a mandolin, etc.

Plein Jeu (*Music*). The French term for Full Organ.

Pleistocene (*Geol.*) Synonymous with Post-Pliocene (*q.v.*), Quaternary, and other names. By some geologists the term is employed for the Glacial Period or Age of Snow. During the Pleistocene Period Britain has undergone some important changes of climate, from one during which snow was precipitated instead of rain to a second, in which dry cold winds prevailed, and to a third, much the same as at present. It includes, so far as man is concerned, the Palæolithic Period, the Neolithic Period, and the Ages of Bronze and of Iron.

Pleochroism (*Min.*) The property some minerals have of appearing of different colours when viewed in different directions. Some minerals are Dichroic (*e.g.* Dichroite or Iolite), some even Trichroic.

Pleonaste (*Min.*) A black variety of Spinel (*q.v.*)

Pliers *or* **Plyers** (*Eng., etc.*) A small pair of pincers for handling small articles; used also for shaping wire.

Plinth (*Architect.*) The slab-like member forming the lowest division of a base of a column, pilaster, or pedestal. Greek bases had no plinth. The term plinth is also used to denote a slightly projecting face at the base of a wall, pier, etc.

Pliocene (*Geol.*) The subdivision of the Tertiary Period during which the percentage of recent species of marine mollusca was *more* than that of the extinct species. The period was pre-eminently the Age of Mammals. That it was one of long duration can be shown by the fact that numerous and important geographical, as well as biological, changes took place within the period. Our British Pliocene Rocks occur chiefly in East Anglia. They include the Cromer "Forest Bed" and the various "Crags," such as the Red Crag, Coralline Crag, etc.

Plot *or* **Plat** (*Mining*). (1) A flat place, especially one on which ore is to be laid or piled. (2) A rough bridge with a flat roadway.

Plotting (*Chem. Eng.*) The process of compressing or "squirting" a milled soap into a compact bar by forcing the ribbons of soap through a nozzle. The process is often called plodding, but the term is really derived from the French *pelotage*.

—— (*Eng., etc.*) Drawing a curve or line through a series of points, the position of which has been determined by calculation, experiment, or otherwise.

Plough (*Bind.*) The instrument used for cutting the edges of a book when it is in the lying press. *See* BOOKBINDING.

Plough (*Carp. and Join.*) A tool with a movable fence, for cutting grooves of various sizes in joinery. *See also* PLANES.

—— (*Elect.*) The conductor which makes contact with the live rail in an electric railway or tramway on the slotted conduit system.

Ploughed and Tongued Joint (*Carp. and Join.*) A joint for joining boards together. The edges are grooved and a tongue inserted.

Ploughshare Vault (*Architect.*) A vault in which the cells (*q.v.*) are winding surfaces. It is a form peculiar to Gothic work.

Plug (*Eng., etc.*) (1) A general term for a piece of material of suitable shape, used for filling up a hole. (2) The movable part of a tap or cock. (3) A piece of iron with a male thread to stop the end of a gas or water pipe.

Plug Centre Bit (*Carp.*) A form of PIN DRILL (*q.v.*) used for making holes in wood.

Plug Gauge (*Eng.*) A cylindrical piece of metal accurately turned to a given size and used as a standard of measurement.

Plug Key *or* **Switch** (*Elect.*) A device for making and breaking a circuit by means of a metal plug fitting a recess between two blocks of metal placed close together.

Plug Tap (*Eng.*) A tap used for finishing off an internal screw thread; it is made without any taper (*q.v.*)

Plum. *See* WOODS.

Plumb. *See* PLUMB LINE, PLUMB RULE.

Plumbago. A popular synonym for GRAPHITE (*q.v.*)

Plumbago Crucibles (*Met.*) Crucibles made of a mixture of ground plumbago and clay. They will stand great heat.

Plumb Bob. The weight used at the end of a plumb line; it is often pointed at its lower end.

Plumber Block (*Eng.*) *See* PLUMMER BLOCK.

Plumber's Cloth (*Plumb.*) The pad used for wiping (*q.v.*) lead pipe joints.

Plumber's Iron (*Build.*) An iron used for overcasting (*q.v.*) a wiped joint.

Plumbing. The execution of lead work in building operations, *i.e.* the formation of lead roofs, flashings, domes, finials, breaks, piping, and various work, not necessarily in lead, which is connected with the foregoing.

Plumb Line (*Eng., Build., etc.*) A cord with a metal weight at the end; used to test the position of lines and surfaces required to be vertical. A vertical line.

Plumb Rule (*Build.*) A narrow piece of board with parallel sides and an egg shaped hole at the bottom end for the plumb bob to swing in. Used by masons, bricklayers, and others for determining a perpendicular.

Plumbum, Plumbic, Plumbous (*Chem.*) PLUMBUM is the Latin name for lead. The chemical symbol for lead, Pb, is derived from the word plumbum. The words plumbic and plumbous are sometimes used in naming lead salts.

Plummer Block (*Eng.*) A casting which carries the brasses forming the bearing of a shaft. The brasses fit into a suitably shaped opening in the block, and are held in place by a CAP bolted to the main casting. The latter is furnished with projections or flanges, by which it is itself bolted down to the baseplate, etc.

Plumping (*Leather Manufac.*) A swelling of the leather during the tanning process, generally dependent on the quantity of acid in the tan liquors.

Plunger (*Eng., etc.*) (1) The piston of a hydraulic press (*q.v.*) (2) The solid piston of a force pump. *See* PUMPS. (3) An implement used to form the interior of certain kinds of cheap glassware when cast in a mould.

Plush (*Silk Manufac.*) A form of velvet having a long pile, usually made in power loom, two widths being woven together face to face, the process of cutting them apart creating the pile.

—— (*Textile Manufac.*) A pile fabric in which the pile is longer than velvet and very frequently consists of mohair yarn. Used for decorative purposes.

Plus Thread. A thread cut on a bolt or rod that has been thickened where the thread occurs, so that the diameter of the substance is not reduced by the thread.

Plutonic Rocks (*Geol.*) Eruptive rocks which have consolidated from a fluid state under very great pressure and at a very slow rate. In most cases, if not in all, they probably represent the deeper seated portions of the great masses whose upper parts have been volcanoes. The exposure of Plutonic Rocks at the surface, therefore, implies upheaval and denudation to an enormous extent. Granite, Syenite, Diorite, and Gabbro are the chief varieties. Plutonic Rocks may be classed, in regard to the depth at which consolidation took place, as Sub-Plutonic, Plutonic, and Ultra-Plutonic.

Pluviometer *or* **Pluviameter** (*Meteorol.*) A rain gauge.

Ply. (1) A bend, turn, or plait. (2) A single thickness or strand.

Pneumatic Action (*Music*). A form of action employed in organ construction to lighten the touch. *See* ORGAN, p. 439.

Pneumatic Mechanism. Mechanism actuated by compressed air, however supplied.

Pneumatics. The science dealing with the mechanics of gases.

Pneumatic Tyres. *See* TYRES.

Pochettino (*Music*). A little: slightly.

Pocket (*Build.*) A term of wide application, signifying an opening or hole, *e.g.* the hole left in brickwork or masonry to receive the end of a joist or girder.

—— (*Carp. and Join.*) The rectangular hole cut in the pulley styles of a cased frame to receive the weights.

—— (*Eng.*) A general term for a recess or cavity in any structure.

—— (*Mining*). A cavity containing a mass of ore which does not form a continuous vein.

Pocket Knife (*Carp. and Join.*) A broad tool similar to a chisel, used for cutting the pockets in sash frames.

Pocket Print (*Foundry*). A core print (*q.v.*) which is not permanently fixed to the pattern, but is detached when the latter is lifted, and withdrawn separately.

Poco (*Music*). Little: rather: as *poco a poco*, little by little, gradually; *poco più mosso*, rather faster.

Podium (*Architect.*) A continuous pedestal, either supporting a range of columns or acting as a parapet. Like a pedestal, it consists of a base, die, and cornice. The term podium is also used to denote the wall surrounding the arena of an amphitheatre. *See* PEDESTAL *and* AMPHITHEATRE.

Podophyllum (*Botany*). A genus of the *Berberidaceæ*, *P. peltatum* (May Apple), yields a medicinal resin extracted from the rhizome and rootlets. The plant grows extensively in the eastern part of North America and in the valleys of the Himalayas.

Poikilitic (*Geol.*) Variegated or mottled. A term applied to the pale green decoloration patches which often occur in red marls or sandstones. Being of common occurrence in the New Red Rocks, the presence of this mottling has led to the whole of the New Red (*i.e.* "Permian" and "Trias" together) being classed as the Poikilitic Series.

Point (*Civil Eng.*) A movable rail used in making a connection between one set of railway lines and another. *See* RAILWAYS.

—— (*Typog.*) The unit of a lineal inch from which the various sizes of types are regulated. It is based on the fact that 72 pica ems are equal to a lineal foot, 12 points to 1 pica em, and 6 pica ems to 1 lineal inch. (*See* TYPES.)

—— *or* **Dot** (*Music*). This sign • placed after a note or rest increases its value by one half. If there are more dots than one, each succeeding dot is one half the value of that immediately before it, *e.g.*  equals . A point or dot placed above or below a note indicates that the note is to be divided into half note, half rest, *e.g.*  equals  This is called staccato (*q.v.*)

Point Bar (*Lace Manufac.*) A suitably shaped bar of iron, extending the whole width of the lace machine, to which the "point leads" are screwed. Each point or needle is adjusted in correct line with each carriage in the machine, and a peculiar dipping movement is communicated to the bar which enables the points to enter between the warp and bobbin threads and forward each twist, from its formation at the end of the carriage, through the few intervening inches to the centre or point where the fabric commences to be formed. *See also* POINTS *and* LACE MANUFACTURE.

Point d'Esprit (*Lace Manufac.*) A fine net, with small but well defined spots.

Pointed Work (*Build.*) (1) Masonry dressed with a pointed tool. (2) Brickwork or masonry in which the joints have been finished off by POINTING (*q.v.*)

Pointers (*Astron.*) Two stars in the constellation Ursa Major (the Great Bear) which point to the Pole Star and enable it to be found easily.

Point Holes (*Print.*) Pricks made in the special positions in the margins of a sheet of paper at the moment of printing. When the sheet is reversed the points are placed in the holes and register the work.

Pointing (*Build.*) Forming and finishing the external joints of brickwork and masonry so as to give a neat appearance to the work. The operation is performed by raking out a portion of the mortar between the joints of brick or stone walls in order to replace it by new mortar, which is finished off or smoothed on the surface with a tool.

—— (*Sculp.*) Marking off points on a clay model to facilitate and ensure accurate reproduction in marble, bronze, etc.

Point Net (*Lace Manufac.*) A net made by the aid of a needle.

Point Net Machine (*Lace Manufac.*) A "warp machine" (*q.v.*)

Point Pass (*Textiles*). *See* ENTERING.

Points (*Lace Manufac.*) A series of needlelike instruments arranged with geometrical precision upon a bar called the point bar (*q.v.*) They serve to take up the twist and crosses or intersections in the net.

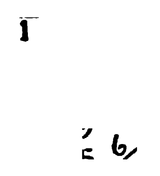
—— (*Print.*) Pins or spurs fastened to the tympan of a hand press, or fixed in the margins of a forme when printed on a cylinder machine, for the purpose of securing register when perfecting the sheet.

Point Screws (*Print.*) A small screw and nut for clamping points to the tympan frame of a hand press.

Points of the Compass. The dial of a compass is divided into four principal quadrants by lines running diametrically across from N. to S. and from E. to W. Each quadrant is bisected by a diameter running N.E. to S.W. and N.W. to S.E. Each of these eight divisions is again divided into four, constituting the thirty-two points of the compass. These points are named as follows:

N.,	N. by E.,	N.N.E.,	N.E. by N.
N.E.,	N.E. by E.,	E.N.E.,	E. by N.
E.,	E. by S.,	E.S.E.,	S.E. by E.
S.E.,	S.E. by S.,	S.S.E.,	S. by E.
S.,	S. by W.,	S.S.W.,	S.W. by S.
S.W.,	S.W. by W.,	W.S.W.,	W. by S.
W.,	W. by N.,	W.N.W.,	N.W. by W.
N.W.,	N.W. by N.,	N.N.W.,	N. by W.

Points of the Shield (*Her.*) The parts denoting the position of any figure. The shield is divided into nine points.



1. Dexter Chief.
2. Middle Chief.
3. Sinister Chief.
4. Dexter Base.
5. Middle Base.
6. Sinister Base.
7. Honour Point.
8. Fesse Point.
9. Nombril Point.

Polar. Belonging or relating to a POLE (*q.v.*)

Polar Axis (*Astron.*) The axis of an equatorial telescope, adjusted to the latitude of the place in question.

Polar Caps (*Astron.*) Some of the planets, *e.g.* Mars and Venus, have white caps at their poles which vary in size according to the planets' seasons.

Polar Climate (*Meteorol.*) The principal characteristics of the climate of the polar or frigid zone, such as the absence of solar rays during a longer or shorter portion of the year.

Polar Distance (*Astron.*) The angular distance of a star from one of the celestial poles. The North and South Polar Distances are abbreviated to N.P.D. and S.P.D.

Polaris (*Astron.*) The North Pole Star, about which all the other stars appear to revolve.

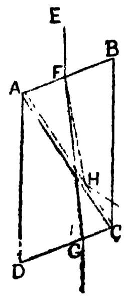
Polarisation in a Dielectric (*Elect.*) Let a unit area be drawn in a dielectric at right angles to any line AB; then the polarisation in the direction AB is the difference between the number of Faraday tubes (*q.v.*) which pass from one side of the area to the other in the direction AB, and the number which pass in the opposite direction, BA.

Polarisation of a Cell (*Elect.*) A temporary decrease in the electromotive force of a cell, owing to certain changes in the substances in contact.

Polarisation of an Electrolyte. The separation of free ions at the electrodes, resulting in the production of an electromotive force in the opposite direction to that producing the separation of the ions.

Polarisation of Light (*Phys.*) Light is said to be POLARISED when the type of the vibration is maintained invariable (*Preston*). In this case every element or particle of the ether describes the same kind of curve in the course of its vibrations; or, more generally, the nature of the disturbance remains permanently unaltered. If the elements are executing vibrations in parallel straight lines, the light is said to be PLANE POLARISED; if the paths are circular, the light is CIRCULARLY POLARISED; if they are ellipses, which are similar and similarly situated, the light is ELLIPTICALLY POLARISED. A beam of plane polarised light has its vibrations confined to a single plane; they are transverse and analogous to the vibrations of a plucked string, all particles of which are executing vibrations in parallel rectilinear paths. Thus the polarised beam is *two sided*, and it is by this property that the existence of the polarisation is detected. Light may be plane polarised in a variety of ways, of which the following are the chief:—(1) BY REFLECTION: Light reflected from any surface is in general partly polarised, *i.e.* the reflected beam is a mixture of polarised and unpolarised, or ordinary, light. The amount of polarisation is a maximum for one particular angle, which is termed the POLARISING ANGLE for the substance. In the case of a transparent substance, when some of the light is reflected from the surface and some is transmitted, the polarising angle is that angle of incidence for which the reflected and the transmitted rays are at right angles; if ϕ be the polarising angle and μ the Refractive Index for the medium, then $\tan\phi = \mu$; this is BREWSTER'S LAW. For glass the angle is about 57°. If, then, ordinary light be incident on a glass plate, or, still better, a pile of plates, at this angle, the reflected ray is plane polarised. (2) BY TRANSMISSION: In the above case it is found that not only the reflected ray, but also the refracted ray, is plane polarised; both portions contain the same amount of polarised light, and their planes of polarisation are at right angles to each other. But whereas the reflected beam is practically completely polarised, the transmitted contains an equal amount of polarised, mixed with a large excess of ordinary light. Each plate acts similarly, hence a sufficient number will completely polarise transmitted rays, when the incident light strikes the surface at the polarising angle. (3) BY DOUBLE REFRACTION (*q.v.*): Both the Ordinary and Extraordinary Ray are plane

polarised in directions at right angles to each other. A pinhole in a card, viewed through a crystal of Calcite, gives two images, the beams of light from each being polarised. A plate of Tourmaline, if cut parallel to the axis of the crystal, will, under the same circumstances, show one image only; two beams are really produced, but the Ordinary beam is absorbed, unless the plate be extremely thin. We thus obtain a single beam of polarised light. For experiments on polarised light we require a device to polarise the light, which is termed a POLARISER, and an ANALYSER, whereby the polarisation may be detected. The two form a POLARISCOPE. Consider a beam which has been plane polarised by any of the means referred to above. Interpose in the path of the beam a second arrangement exactly similar to that by which the light was originally polarised. This forms the Analyser. If the two polarising devices be similarly situated (*i.e.* if the second one be so placed that it will polarise a beam of ordinary light in the same plane as the first does), then the beam passes through both Polariser and Analyser. Now rotate the Analyser; the transmitted beam diminishes in intensity, and becomes completely extinguished when the Analysis has been turned through a right angle. If we suppose the Polariser to be so placed that the vibrations which it transmits are confined to a *horizontal* plane, then the Analyser will be so turned that it only transmits vibrations in a *vertical* plane; therefore, if the vibrations are of a transverse nature, none can pass through the two in succession, and extinction of the beam occurs. The most usual method of polarising light is by means of a NICOL'S PRISM, or, as it is often termed, a NICOL. A crystal of Iceland Spar, ABCD, is cut across along AC, and the two halves cemented together by a film of Canada Balsam. The Index of Refraction of this substance is less than that of the crystal for the Ordinary Ray, but greater than its value for the Extraordinary Ray. When a ray EF entering the prism is split up into two rays FH and FG by double refraction (*q.v.*), it is therefore possible to get rid of the Ordinary Ray by total internal reflection (*q.v.*) at H, while the Extraordinary Ray passes through, and emerges at G as a plane polarised ray.



A Nicol Prism can be used either as a Polariser or Analyser. Various other polarising prisms have been invented, varying chiefly in the methods employed in order to effect a separation of the two rays of polarised light produced in a doubly refracting medium. When the Polariser and Analyser of a polariscope are so placed as to cut off the passage of light, they are said to be "crossed." Any doubly refracting transparent substance placed between the crossed Polariser and Analyser will (except in certain positions) cause light to pass. This is because the velocity of light in the substance varies with direction of path, and the form of the incident vibration hence passes through cycles of change of the Lissajou figure type, but limited to straight line, ellipse, and circle, so that the beam may emerge elliptically or circularly polarised, and then its vibrations cannot be completely stopped by the Analyser. This effect, common to all doubly refracting substances, must be distinguished from the ROTATION OF THE PLANE OF POLARISATION produced by a few crystals, of which quartz is the most important, and by many organic liquids and solutions. In this case the emergent beam is still plane polarised, but its direction of vibration has been rotated through a certain angle. If this rotation is clockwise, *looking along direction the light travels*, it is said to be RIGHT HANDED, and *vice versâ*. It may be distinguished from ordinary double refraction as follows: A plate of any doubly refracting substance cut perpendicular to the axis does not restore light when placed between crossed Polariser and Analyser, behaving like ordinary bodies. But a plate of quartz so cut *does* give light, which with white light goes through a sequence of colours, but cannot be extinguished by rotating Analyser. With monochromatic light the field can be darkened by rotating analyser, and thus the angle of rotation measured. The rotation is said to be RIGHT HANDED if it appears to the observer to be in the direction of the hands of a clock, LEFT HANDED if in the reverse direction. The amount of rotation is proportional to the thickness of the layer of the substance through which the light passes, and (in the case of solutions of optically active substances) to the strength of the solution. The latter property affords a convenient means of comparing the strengths of solutions of a given optically active substance (*e.g.* sugars). The solution is placed in a tube having its ends closed by flat plates of glass; the tube is inserted between the Polariser and Analyser, and the rotation of the latter measured by means of a circle divided into degrees and provided with a vernier. To enable the exact position of extinction to be observed, some additional device is commonly used in conjunction with the Analyser proper. That due to Laurent, termed a HALF SHADE analyser, consists of a semicircular plate of quartz cut parallel to the axis, and joined to a similar semicircle of glass of suitable thickness. When the two halves of this composite disc appear equally illuminated, the Analyser has been turned into the exact position. The BI-QUARTZ Analyser has two semicircles of quartz, one being right handed, the other left handed in their action on plane polarised light. The two halves show in general different colours, but assume the same tint when the Analyser is correctly adjusted. An instrument for comparing the rotation produced by liquids is chiefly used in estimating the strength of sugar solutions, and is consequently termed a SACCHARIMETER. The POLARISING MICROSCOPE is much used in the study of minerals. It consists of a microscope provided with a polariser and an analyser, generally formed by Nicol prisms. Minerals examined by polarised light show distinctive characteristics, and therefore the polarising microscope is much used by petrologists and mineralogists in the identification of those minerals which are naturally transparent or which can be cut into sufficiently thin slices to enable them to transmit light. A great number of phenomena are produced by polarised light under different circumstances. If the light form a convergent or divergent beam, plates of doubly refracting material (*e.g.* crystals) give a variety of geometrical patterns, depending on the direction of the axis of the crystal, whether it be uni-axal or bi-axal, etc. These patterns form rings, crosses, and complex series of curves. If the original light be white, these are brilliantly coloured: if monochromatic, they are simply light or dark bands. To show these figures, an arrangement of lenses is used to cause the light to form a convergent beam before passing through the substance to be examined. Such an arrangement may be fitted to an ordinary table polariscope, a lantern polariscope for projection on the screen, or to a polarising microscope.

Polariscope. *See* POLARISATION OF LIGHT.

Polarised Light. *See* POLARISATION OF LIGHT.

Polarised Relay (*Elect. Eng.*) A RELAY (*q.v.*) having a permanent magnet instead of a core of soft iron.

Polariser (*Light*). *See* POLARISATION OF LIGHT.

Polarity. The possession of magnetic poles; the property acquired by a magnetisable body when brought into a magnetic field.

Polar Radius of the Earth. *See* RADIUS OF THE EARTH.

Polar Relay (*Elect. Eng.*) *See* POLARISED RELAY.

Pole Armature (*Elect. Eng.*) *See* ARMATURE.

Pole Lathe. A primitive lathe with Dead Centres (*q.v.*) in which a cord is wrapped round the work. One end of this cord is attached to a treadle, the other end to a flexible pole. Rotation is produced by pressing the treadle, and then releasing it, the pole drawing the cord up again. The pole lathe is still met with occasionally, *e.g.* it is used in the production of chair legs in the High Wycombe district. In Eastern countries it is fairly common.

Pole Plate (*Carp. and Join.*) The horizontal timber that supports the feet of the rafters of a roof over a void. *See* ROOFS.

Poles (*Elect.*) The terminals of a cell, condenser, etc.

——, **Celestial** (*Astron.*) Two points situated 90° from the celestial equator, or two points in the sky where a star would have no diurnal motion.

——, **Magnetic.** In general language, the ends of a magnet or magnetised bar; the parts of the magnet at which the magnetic properties appear to be chiefly concentrated. If the poles of a magnet were true mathematical points, then the lines of force would start off radially from these points. This condition is never fulfilled, but is most nearly approached in the spherical ended magnets invented by Robeson and Searle. *See* ROBESON MAGNETS.

——, **Terrestrial** (*Astron.*) The extremities of the Earth's axis.

Poles of a Great Circle (*Geom.*) The two points situate 90° from the circumference of a great circle; the extremities of the axis of the great circle, *i.e.* the extremities of that diameter of a sphere which is at right angles to the great circle. *See also* SPHERE.

Polianite (*Min.*) Manganese dioxide, MnO_2: tetragonal and isomorphous with tinstone. Compare with the allotropic PYROLUSITE.

Poling (*Met.*) The reduction of the copper oxide in Blister Copper by the insertion of a pole of green wood. The gases evolved from the wood serve as reducing agents, and also cause the fluid metal to splash up and come into intimate contact with a layer of pure anthracite or charcoal, which is spread on the surface. When the process has been carried sufficiently far, the metal is said to be at TOUGH PITCH, and is ready for use. If the process is incomplete, the metal is said to be DRY or UNDERPOLED, and is brittle; while if carried too far, the metal is OVERPOLED, and must be slightly oxidised by the exposure of the surface of the fluid metal to the action of the air.

Poling Boards (*Build., etc.*) The retaining boards that prevent the earth from falling, in a trench.

Polisher or Polishing Iron (*Bind.*) A steel finishing tool which is heated and passed over the back and sides of leather bindings to smooth down burrs and impart a gloss to the leather.

Polishing Lathe or Head (*Eng., etc.*) A small headstock fitted with a mandrel carrying a rapidly rotating polishing wheel or brush.

Polishing Stick (*Eng., etc.*) A strip of wood covered with emery or buff leather, used for polishing metal work in the lathe.

Polishing Wheel (*Eng., etc.*) A small wheel coated with buff leather, or covered with fine emery, carborundum, or other polishing powder.

Polissoir (*Glass Manufac.*) A block of wood attached to a rod of iron with which the flattener transforms the cylinders into flat sheets. *See* SHEET GLASS *and* GLASS MANUFACTURE.

Pollard Oak Graining (*Dec.*) Is a favourite method of imitating wood by British grainers. The wood imitated is supposed to be old stumps of trees having a variety of grain almost equal to French walnut. It is sometimes called "root of oak." The ground colour is made by mixing yellow ochre and white lead with a little Venetian red and dark umber until the requisite depth is obtained. It should, however, be lighter than walnut. The graining is done with raw and burnt sienna, Vandyke brown and burnt umber, and a little ivory black and ultramarine may also be employed.

Pollen (*Botany*). Minute grains containing the male element necessary for fertilisation in a flowering plant.

Polonium (*Chem.*) The first radioactive element isolated by the Curies from pitchblende. It seems doubtful if it is really an element. *See* RADIUM.

Polybasite (*Min.*) A silver sulphantimonite, $9Ag_2S \cdot Sb_2S_3$. Rhombic; colour, iron black. It contains about 70 per cent. of silver, and hence is very valuable when in sufficient quantity. From Mexico, Chili, etc.

Polygon. A plane figure, bounded by straight lines, more than four in number.

Polygonaceæ (*Botany*). A dicotyledon order, including the Dock, Rhubarb, and Buckwheat.

Polygonal Rubble (*Build.*) Masonry built of stones worked to polygonal shape.

Polygon of Forces. *See* GRAPHIC STATICS.

Polyhedral Angle. The figure produced by four (or more) planes which meet at a point.

Polyhedron. A solid bounded on all sides by plane surfaces.

Polymer (*Chem.*) *See* POLYMERISM.

Polymerisation (*Chem.*) *See* POLYMERISM.

Polymerism (*Chem.*) The union of two or more molecules of the same substance to form a more complex molecule which can be resolved on heating into its components. The actual change is called polymerisation: the original simple molecule and the final complex molecule are called polymers. Substances are also called polymeric when the molecular formula of one of them is an exact sub-multiple of that of the others, even when the substances are not mutually convertible into each other. Polymerisation is distinguished from condensation (*q.v.*) by the reversibility of the former process. In many cases the molecular weight of the polymer is unknown; in such cases the formula of the polymer of unknown molecular weight is expressed by writing down that of the substance which has undergone polymerisation and adding the suffix *n*. Examples: Common

phosphorus, P_4, polymerises on heating to red phosphorus, $(P_4)_n$. Aldehyde, C_2H_4O, polymerises on standing to paraldehyde, $(C_2H_4O)_3$, and, on adding a little strong sulphuric acid and keeping the temperature below 0°, to metaldehyde, $(C_2H_4O)_n$. Many other aldehydes also polymerise. Unsaturated hydrocarbons and their halogen substitution products very commonly polymerise; *e.g.* acetylene, on heating, forms benzene, $3C_2H_2 = C_6H_6$; and monochloracetylene easily polymerises to trichlorbenzene, $3C_2HCl = C_6H_3Cl_3$; cyanogen, C_2N_2, polymerises to $(C_2N_2)_n$, and cyanic acid, CHNO, to cyanuric acid, $C_3H_3N_3O_3$.

Polymorphism (*Min.*) Crystallisation of a mineral in more than three different systems.

Polyoses *or* **Polysaccharides** (*Chem.*) See CARBOHYDRATES.

Polyphase Currents (*Elect. Eng.*) Two or more alternating currents differing from each other in phase by a constant amount.

Polyphase Dynamo *or* **Generator** (*Elect. Eng.*) A dynamo for producing polyphase currents. See DYNAMO.

Polyphase Motor (*Elect. Eng.*) A motor worked by a polyphase current.

Polysaccharides *or* **Polysaccharoses** (*Chem.*) Substances belonging to the carbohydrate class, such as starch, cellulose, dextrines, glycogen, inulin, etc., all of unknown and probably high molecular weight, and having the empirical formula $(C_6H_{10}O_5)_n$.

Pomposo (*Music*). Pompously.

Ponty (*Glass Manufac.*) A tapering solid rod of iron sometimes called the WORKING IRON. See GLASS MANUFACTURE.

Poor Lime (*Build.*) A lime containing from 15 to 30 per cent. of impurities insoluble in acid.

Poplar. See WOODS.

Poplin (*Textile Manufac.*) A plain cloth, woven as tabby, with a fine ribbed lustrous appearance. Made from silk warp and a fine worsted shoot. Inferior grades are made without any silk.

Poppet (*Eng.*) The loose head of a lathe which supports the end of a long piece of work.

Poppyhead (*Architect.*) An ornament used occasionally in Decorated and frequently in Perpendicular Gothic architecture, as a termination to bench ends in churches. These poppyheads were frequently richly carved either with leaves or grotesque figures.

Poppy Oil (*Dec.*) This oil is obtained either by pressure or by means of solvents from the seeds of the opium poppy (*Papaver somniferum*). The best varieties are almost white. The drying qualities of poppy oil are almost equal to those of linseed oil. It is used principally by artists, but abroad it is frequently employed for grinding white paints, such as zinc oxide and white lead, where a brilliant white surface is desired. Specific gravity, ·924 to ·926.

Porcelain. A specific kind of pottery manufactured from highly refined earths and mineral salts. In the process of manufacture it loses its earthy character and becomes a new and valuable material. It is characterised mainly by purity of colour and a fine translucency, even when made comparatively thick. It is non-absorbent and highly resonant when struck. See POTTERY AND PORCELAIN.

Porcupine Roller (*Lace Manufac.*) An intermediate roller either with inserted pins or covered with wire card-cloth. It is contiguous to the work roller, and serves to give a more constant "take up" of the fabric. It also ensures greater regularity in the quality of the manufactured web.

Porgie. The raw material (partly offal) from which fish oil is extracted. The term is chiefly peculiar to the Atlantic Coast of North America. Also termed MENHADEN.

Porous Pot *or* **Cell.** A vessel of unglazed earthenware used in primary cells, through the material of which the fluids of the cell can percolate, thus establishing electrical connection (through the walls of the pot) between the inner and outer parts.

Porphyrite (*Geol.*) A name originally employed in a very loose sense to denote a decomposed lava somewhat near andesite in composition, so that even trachyte lava and basalt lava sometimes went by this name. The modern use of the word is limited to the trappean representatives of the diorites at the one end of the series and the andesite at the other. The rock consists essentially of plagioclase felspar and ferromagnesian silicates, generally exclusive of olivine, in about equal proportions to each other, and in which the structure consists essentially of an older generation of larger idiomorphic crystals of these minerals set in a finer grained matrix of the same minerals of later consolidation.

Porphyritic Structure (*Geol.*) Many eruptive rocks have consolidated in part under an earlier set of conditions, and partly and finally under another. Under the earlier conditions certain of the constituents separate out and complete their growth, while the remainder of the rock is still fluid. Under the later conditions, which are usually those of lesser pressure and lower temperature, the crystallisation of the remainder takes place. Hence the earlier generation of crystals may present some special characteristic, usually in regard to size, as compared with those of the later generation. The present term usefully expresses that fact.

Porphyry (*Geol.*) A lithological term now seldom employed in scientific descriptions on account of the loose and ill-defined manner in which it was used. It originally meant (as its name implies) a certain eruptive rock of a purple colour. Then it came to be used for any kind of eruptive rock in which there was a conspicuous development of large idiomorphic crystals in a finer grained base.

Porpoise (*Zool.*) The genus *Phocæna* of the Cetacean family *Delphinidæ*. The porpoises are found in shoals in the seas around our coasts. The oil and skin are used in manufactures.

Porpoise Oil. Sometimes sold as "brown fish oil"; is obtained by boiling the flesh and fat of the porpoise. The specific gravity at 15° C. is 0·922.

Porry (*Silk Manufac.*) The stretch of warp from cane roll to harness, in which the lease or cross rods are placed.

Port (*Eng.*) See PORTS.

Portable Engine. Small engines mounted on wheels for removal by horses, etc., but distinguished from TRACTION ENGINES (*q.v.*) or road locomotives, which can travel by their own motive power. The ordinary pattern resembles the traction engine in form, and has a similar boiler to a locomotive.

Portamento, Portando (*Music*). Gliding from one note to another.

Portcullis (*Architect.*) A gate of iron or of wood strengthened with iron. It slid vertically in coulisses or channels formed in the jambs of a gateway, and was used in Roman and Gothic architecture for the purpose of defence. An ornament resembling a portcullis was frequently used in the Perpendicular style of Gothic architecture.

—— (*Her.*) Representations are used in heraldry, and the portcullis was a device of the Beauforts, thence by descent that of the Tudors, and was used by the Tudor Henrys. Also used by Westminster City and Abbey. One of the pursuivants of the College of Arms is entitled Portcullis.

Portee (*Silk Manufac.*) Twice the usual number of threads passing from warp bobbins on to the mill in the process of hand warping. Warping from forty-one bobbins (a number often used when organzine is fine), the ends from these bobbins passing once on to the mill, to the required length of the warp, is a HALF PORTEE.

Porter (*Linen Manufac.*) This term is used in Scotland as an equivalent to beer in Ireland, and means forty threads of warp. *See* BEER.

—— (*Met., etc.*) A bar attached to a forging or fagot (*q.v.*), by which it is held during hammering.

Port Holes (*Eng.*) *See* PORTS.

Portico (*Architect.*) A colonnade in front of a classic or Renaissance building. *See* COLONNADE PERISTYLIUM *and* STOA.

Portico "in-antis" (*Architect.*) *See* ANTA.

Portland Beds (*Geol.*) Rocks of marine origin pertaining to the Upper Jurassic Series overlying the Kimeridge Clay, and followed by the estuarine and fluviatile Purbeck and Wealden Strata, which form the uppermost part of the Jurassic Rocks in Britain. The Portland rocks are best exposed on the south coast of England, where they yield building stones of great value.

Portland Cement (*Build.*) An artificial hydraulic cement composed of the diluvial clay of the valleys of our chief rivers, mixed in definite proportions with the chalk of the same geological districts. These materials are finely comminuted in mills, mixed with water, allowed to deposit, then desiccated and burnt to a point which produces vitrification. *See* CEMENTS.

Portland Stone. *See* BUILDING STONES.

Portland Vase. *See* VASES.

Portrait Gallery, National. *See* NATIONAL PORTRAIT GALLERY.

Ports (*Eng.*) The openings by which steam enters and leaves the cylinder of an engine.

Porty (*Foundry*). A moulder's name for a large core print.

Posaune (*Music*). (1) Trombone. (2) An organ reed stop of rich and powerful tone—of 8 ft., 16 ft., or 32 ft. tone. *See* ORGAN, p. 441

Pose (*Art*). The attitude or posture assumed by an individual for artistic purposes. The attitude of a painted or sculptured figure.

Positif (F.), Positiv (G.) (*Music*). Choir organ. *See* p. 440.

Position Circle (*Astron.*) A divided circle fitted to telescopes for the measurement of angles of position.

Position Isomerism (*Chem.*) *See* ISOMERISM.

Positive (*Music*). The German name for Choir Organ. *See* ORGAN, p. 440.

—— (*Weaving*). As applied to a shedding motion, a positive tappet or dobby is one which controls the movement of a heald in either an upward or a downward direction. *See* NEGATIVE.

Positive Charge (*Elect.*) A charge of electricity of the same kind as that produced when a glass rod is rubbed with silk.

Positive Crystal (*Phys., etc.*) A UNIAXAL CRYSTAL (*q.v.*) in which the velocity of the Extraordinary Ray is (except along the Optic Axis) less than that of the Ordinary Ray. Quartz and Ice are examples of positive crystals. *See also* DOUBLE REFRACTION.

Positive Direction of Lines of Force (*Elect.*) The direction along which a positive charge or positive pole would travel if free to move through the medium in which the lines of force are situated.

Positive Lead, Wire, etc. (*Elect. Eng.*) The wire, etc., connected to the positive terminal of a source of electric current.

Positive Pole (*Elect.*) The terminal connected to the copper plate or its equivalent in a primary cell; the corresponding terminal, *i.e.* the one from which the current flows, in the case of a dynamo, etc.

Positive Stress (*Eng.*) A compressional, as distinguished from a tensional stress.

Post (*Paper*). Printing paper 19½ in. by 15¼ in. in size.

—— (*Paper Manufac.*) A pile of hand-made sheets of paper in the wet state, separated by "felts."

Postern (*Archæol.*) A narrow door or gate affording entrance for foot passengers to a fortified town or castle.

Poster Stick (*Typog.*) A long wooden composing stick, used for broadside and poster work.

Post Horn (*Music*). An instrument of various lengths giving the sounds of the 2nd, 3rd, 4th, 5th, and 6th harmonics of the fundamental note, originally used by mail drivers.

Posticum (*Architect.*) *See* CELL.

Post Office Box (*Elect.*) A form of Wheatstone's Bridge, convenient for transit and used in the Postal Service. *See* WHEATSTONE'S BRIDGE.

Post-Tertiary (*Geol.*) A term somewhat ambiguous in its application; but it is most commonly understood to refer to the geological period which succeeded the Late Pliocene. It thus embraces the whole of the Age of Snow (or Glacial Period) and all the time since. Its chronological value in terms of centuries may be gathered from the fact that nearly the whole of Etna, 11,000 ft. high, has grown up in that time, and that, too, at a rate which has been estimated at 1 ft. in three hundred years.

Pot (*Met.*) A general term for a crucible.

Pot Arch (*Glass Manufac.*) A small kiln or furnace in which the pots are burnt previous to being transferred to the melting furnace.

Potash (*Chem.*) A name rather inexactly used to indicate either potassium hydroxide or potassium carbonate; the context generally enables one to tell which compound is meant. It is rarely, if ever, used in scientific chemistry.

Potash Alum (*Chem.*) *See* ALUM.

Potash Mica (*Min.*) A synonym for Muscovite (*q.v.*)

Potassium (*Chem.*) K. Atomic weight, 39·2. Shining bluish white metal; crystallises in octahedra; melts at 62·5°; boils at 667°, giving a green vapour with characteristic absorption spectrum; specific gravity, 0·875 at 13°. The molecular weight determined by the lowering of the vapour pressure in mercury solution indicates a monatomic molecule; value obtained 30 instead of 39. It dissolves in liquid ammonia, forming a blue solution containing the compound potass-ammonium, $K_2N_2H_6$. It is not oxidised in perfectly dry air or oxygen; but in presence of moisture it is almost instantly oxidised. Burns with a violet flame on heating in air or oxygen. Decomposes water at the ordinary temperature, evolving so much heat that the hydrogen liberated is ignited and burns with a flame coloured violet by vapour of the metal, $2K + 2H_2O = 2KOH + H_2$. It forms an amalgam with sodium, which is liquid at the ordinary temperature and has the appearance of mercury. This amalgam is used in making thermometers which will indicate a higher temperature than the boiling point of mercury. Potassium occurs in many silicates; *e.g.* orthoclase (*q.v.*), often called potash felspar: as sylvine, KCl; as carnallite, $KCl.MgCl_2 6H_2O$; as kainite, $K_2SO_4MgSO_4MgCl_2 5H_2O$, all in the Stassfurt deposits: in many mineral springs, and as an essential constituent of the bodies of plants and animals. Potassium was formerly obtained by distilling an intimate mixture of potassium carbonate and charcoal at a very high temperature; but the yield was bad. The method now employed is the electrolysis of fused caustic potash; but, owing to the ease with which potassium catches fire, the kathode must be enclosed. Perfectly dehydrated caustic potash is used; the anode consists of sheet iron, and the kathode of an iron wire (3 mm. thick), which passes through the bottom of a magnesite crucible which is suspended mouth downwards in the melted caustic potash. The crucible is withdrawn by allowing the charge to nearly solidify; then its contents are broken up under naphtha.

Potassium Compounds. POTASSIUM HYDRIDE, KH. Slender white needles; decomposed by water, forming caustic potash and hydrogen; takes fire in oxygen and in chlorine; heated in ammonia gas at 400°, it forms potassamide, KNH_2; it unites with carbon dioxide directly, with quantitative production of potassium formate, much heat being developed, so that cooling may be necessary—$KH + CO_2 = HCOOK$. The hydride is formed by heating potassium in dry hydrogen at 360°. POTASSAMIDE, KNH_2: a white crystalline solid; melts at 273°; sublimes over 400°; decomposed by water into caustic potash and ammonia; with nitrous oxide it yields the potassium salt of azoimide. It is obtained by heating potassium in a silver boat in a current of dry ammonia gas. OXIDES: POTASSIUM MONOXIDE, K_2O, has not been obtained pure. When potassium is melted and the theoretical amount of dry air is brought in contact with it, the product contains unchanged potassium. POTASSIUM PEROXIDE *or* TETROXIDE, K_2O_4, is a yellow solid; gives up oxygen on being strongly heated; behaves as a strong oxidising agent; *e.g.* with sulphur and phosphorus it forms sulphate and phosphate; decomposed by water, forming caustic potash, hydrogen peroxide, and oxygen; with dilute sulphuric acid at a low temperature it is said to form hydrogen tetroxide, H_2O_4 (Ozonic acid). It is obtained by melting potassium in an atmosphere of nitrogen, and then gradually displacing the gas by oxygen, which combines to form the tetroxide. POTASSIUM HYDROXIDE, KOH (often called potassium hydrate and caustic potash). A white brittle solid usually met with in the form of sticks which have been cast; deliquescent, and very soluble in water (2 parts KOH in 1 part H_2O). It is a powerful alkali, uniting with all acids to form salts. On this account it readily absorbs carbon dioxide from the air. It dissolves readily in alcohol, and the alcoholic solution is an important reagent in organic chemistry when it is desired to remove the elements of an acid from an organic compound which would be hydrolysed if aqueous caustic potash were used; *e.g.*

$$\underset{\text{Ethyliodide.}}{C_2H_5I} + KOH = KI + H_2O + \underset{\text{Ethylene.}}{C_2H_4}$$

It is used in making soap. A method of obtaining caustic potash has been described under ALKALI (*q.v.*) Another method, which is worked on a very large scale, is the electrolysis of a solution of potassium chloride in water. The electrolysis is effected by one or other of two methods, each having for its object the prevention of any action of the chlorine which is liberated in the electrolysis on the caustic potash or potassium, as the case may be. The first of these methods is known as the diaphragm process. Several varieties of this process are in use; one of them is as follows: A large iron vessel contains a series of cells made of cement and provided with earthenware covers; between every two cells is suspended an iron plate, and the iron vessel and iron plates are all connected together and form the kathode. The cement cells all stand on insulating porcelain feet, and through the cover of each there passes a carbon rod, a tube reaching nearly to the bottom of the cell, and a delivery tube. All the carbon rods are joined together and form the anode; the long tube serves for charging the cell with potassium chloride; the delivery tube serves for the escape of the chlorine which is used in making bleaching powder. The electrolysis is carried out at 80 to 90°, and it is stopped when the strength of the caustic potash at the anode attains a certain value, beyond which the manufacturer finds it inadvisable to go. Then the kathode liquid is drawn off and concentrated, unchanged chloride separates out, and a very pure product is obtained. The second method is known as the mercury process. Several varieties of this process are in use; one of them, the Castner-Kellner, is as follows: The cell is made of slate, and is divided into three partitions by two slates, all three compartments communicating at the bottom by means of small holes in the partition slates.

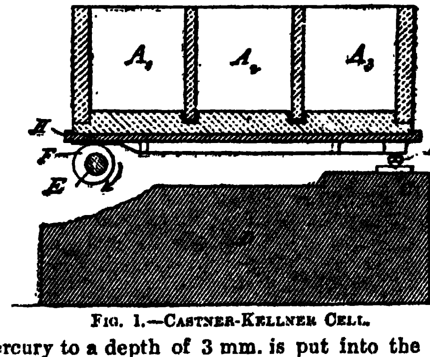


FIG. 1.—CASTNER-KELLNER CELL.

Mercury to a depth of 3 mm. is put into the cell, a solution of the chloride in partitions A_1, A_3 (fig. 1),

and water in partition A_2. The solution is kept about 60°. The anodes are carbon rods placed in the end partitions, and the kathode is an iron plate in the middle partition. Nearly pure chlorine (95 to 97 per cent.) escapes from the end partitions, and the metal alloys with the mercury; the amalgam is brought into the middle partition by rocking the cell, when the metal decomposes the water, forming caustic potash, and the mercury returns to the end partitions. The rocking is effected by resting one end of the cell on an eccentric F, and the other end on a pivot or knife edge B, the eccentric alternately raising and lowering its end of the cell by a distance above and below the horizontal equal to the depth of the mercury in the cell, while the rate of its revolution is such that the mercury has time to acquire its level in each position. When the solution in the middle partition attains a strength of about 25 per cent. caustic potash, it is withdrawn and evaporated. Pure caustic potash may be made on a laboratory scale by heating potassium nitrate with copper foil for several hours to redness in a copper crucible, extracting with water, and evaporating the clear solution in a silver basin. POTASSIUM CHLORIDE, KCl, closely resembles common salt, only it is more soluble in hot water and less soluble in cold water; at 30° the maximum solubility is the same for both, 37 parts in 100 parts water. It melts at 730°. Its occurrence has been mentioned under POTASSIUM (*q.v.*) It is obtained from carnallite by heating it to its melting point (175°), when potassium chloride separates out, and on cooling a further quantity separates, the magnesium chloride remaining dissolved in its water of crystallisation. This salt is used in the preparation of most of the other potassium compounds and also as a manure. POTASSIUM BROMIDE, KBr, is a white solid, crystallising in cubes; melts at 722°; very soluble in water. Largely used in the preparation of silver bromide for photographic purposes, and in medicine in nervous diseases, and as a hypnotic. It is prepared by the action of bromine on iron filings in presence of water, forming a mixture of ferrous and ferric bromides, and decomposing this mixture with potassium carbonate, filtering and crystallising the solution; also by dissolving bromine in a solution of caustic potash, evaporating to dryness, and heating the mixture of bromide and bromate with charcoal. The residue is redissolved, filtered, and crystallised. POTASSIUM IODIDE, KI, closely resembles the bromide in appearance, melts at 685°, and is exceedingly soluble in water. Its solution in water readily dissolves iodine, and from the red solution lustrous black crystals of the tri-iodide, KI_3, separate on evaporation over sulphuric acid. It is largely used in the preparation of other iodides and in medicine. Its preparation is just like that of the bromide. POTASSIUM CHLORATE, $KClO_3$, is a white solid crystallising in shining plates; melts at 359°; at 15°, 100 parts of water dissolve 5 parts of the salt; at 100°, 60 parts. At 372° it begins to give off oxygen, and on continued heating it loses all its oxygen. Traces of chlorine are always evolved in this reaction. If the temperature is kept below that at which potassium perchlorate decomposes, the latter salt is formed as an intermediate product in large amount. On account of the ease with which the chlorate gives up oxygen it is largely used for this purpose. Mixtures of carbon, sulphur, and red phosphorus respectively with the chlorate are easily ignited, and the two latter mixtures explode on percussion; a mixture of antimony sulphide and the chlorate also ignites easily, and this mixture is used in tipping safety matches. With hydrochloric acid, on gentle warming, a mixture of chlorine and chlorine peroxide is evolved, the proportions of the two gases varying with the proportions of chlorate and acid and with the temperature. With sulphuric acid it explodes violently, unless the temperature is kept low; then it forms chloric acid and potassium hydrogen sulphate; on warming, the former decomposes, giving chlorine peroxide and perchloric acid. It is used as an oxidising agent, *e.g.* in the destruction of organic matter in testing for poisons, in the preparation of the dye aniline black, in fireworks, and in making matches; it is also used in medicine. On a small scale it can be made by passing chlorine into a hot and strong solution of potassium hydroxide, $3Cl_2 + 6KOH = 5KCl + KClO_3 + 3H_2O$. On the large scale it is prepared by electrolysis of a solution of potassium chloride; to the solution of chloride a little potassium chromate is added (it appears to form a precipitate of chromium chromate at the kathode, which acts as a diaphragm); the temperature is kept at 60° to 80°; the electrodes are of platinum, or the kathode may be of nickel, and the liquid must be kept stirred all the time. The mixture of chloride and chlorate obtained, in both cases, can be separated by taking advantage of the fact that the chlorate is more soluble in water than the chloride above 95°, while the reverse is the case below 95°. Also, potassium chlorate is less soluble the more chloride there is in solution; *e.g.* at 20° with 50 grs. chloride per litre the solubility of the chlorate is 36·5 grs. per litre, while with 180 grs. per litre of chloride the solubility of the chlorate is 20 grs. per litre: more than 180 grs. per litre of chloride at 20° does not affect the solubility of the chlorate. POTASSIUM CARBONATE, K_2CO_3, is a white, indistinctly crystalline solid; melts at 879°, with some decomposition; very soluble in water (100 parts water dissolve 112 parts carbonate at 20°); deliquescent. Its solution is strongly alkaline, owing to hydrolysis. On the small scale it can be obtained by passing carbon dioxide into one half of a given solution of caustic potash till it is saturated, and then adding the other half: $KOH + CO_2 = KHCO_3$: $KHCO_3 + KOH = K_2CO_3 + H_2O$. Its manufacture has been described under alkali (*q.v.*) It is largely used in the manufacture of other potassium compounds. POTASSIUM HYDROGEN CARBONATE, $KHCO_3$, also called bicarbonate of potash, is a white crystalline solid; decomposes at 190° into carbon dioxide and potassium carbonate; less soluble in water than the carbonate (100 parts of water dissolve 33·2 parts at 20°); its solution decomposes on boiling in the same way as the dry salt on heating. It is obtained by saturating either a solution of the carbonate or of the hydroxide by carbon dioxide. It is used in medicine, *e.g.* in dyspepsia and in gout. POTASSIUM PERCARBONATE, $K_2C_2O_6$, a bluish white amorphous powder; easily decomposed on heating, $K_2C_2O_6 = K_2CO_3 + CO_2 + O$; soluble in water at 0°, but decomposed by water at the ordinary temperature, $K_2C_2O_6 + H_2O = 2KHCO_3 + O$; with acids and alkalis it gives hydrogen peroxide. It oxidises in much the same way as hydrogen peroxide; thus it oxidises lead sulphide to sulphate, and liberates iodine from potassium iodide at 0°; with peroxides oxygen is evolved: $MnO_2 + K_2C_2O_6 = MnCO_3 + K_2CO_3 + O_2$. It is prepared by electrolysing a saturated solution of potassium carbonate at −10° to −15°, when it separates as a bluish solid; it must be quickly filtered off and dried on a porous plate in a stream of dry air: it is never free from

carbonate and bicarbonate. POTASSIUM CYANIDE, KCN, a white crystalline solid, but usually met with cast in sticks; very soluble in water; sparingly soluble in cold alcohol; more soluble in hot alcohol, from which it can be crystallised; very poisonous. It is a powerful reducing agent, so that when heated with metallic oxides it reduces many of them, *e.g.* the oxides of lead, tin, etc., $Pb_3O_4 + 4KCN = 3Pb + 4KCNO$; on this account it is used in blowpipe analysis. When heated with sulphur it unites directly, forming potassium sulphocyanate. In aqueous solution it is hydrolysed, $KCN + H_2O = KOH + HCN$, so that the solution is alkaline, smells of prussic acid, and is as poisonous as this acid, and is slowly hydrolysed to formic acid (potassium formate), $HCN + 2H_2O = HCOOH + NH_3$. With strong sulphuric acid it gives carbon monoxide—no doubt from formic acid produced in hydrolysis of the first liberated hydrocyanic acid. All dilute acids decompose it, liberating prussic acid. Its aqueous solution dissolves platinum, and its dilute aqueous solution with access of air dissolves gold. *See* GOLD. Its solution dissolves many cyanides which are insoluble in water; hence its use in preparing the solutions used in the electrolytic deposition of silver and gold. It is obtained by heating potassium carbonate and carbon at a very high temperature in a stream of nitrogen or of ammonia: in the former gas the heating is done in an electric furnace with carbon electrodes; in the latter the temperature is only 900°, but the ammonia is compressed to one and a third atmospheres. A mixture of sodium and potassium cyanides, which serves the same purposes as potassium cyanide, is made by heating potassium ferrocyanide (anhydrous) with sodium, $K_4Fe(CN)_6 + 2Na = 4KCN + 2NaCN + Fe$. To obtain pure potassium cyanide the vapour of prussic acid is passed into an alcoholic solution of caustic potash—the pure salt separates out. POTASSIUM FERROCYANIDE, $K_4Fe(CN)_6$, is a white solid. Ordinarily the salt is met with in yellow crystals, which contain $3H_2O$; in this form it is commonly called Yellow Prussiate of Potash. It is soluble in water. On heating it alone it gives potassium cyanide, $K_4Fe(CN)_6 = 4KCN + Fe + C_2 + N_2$; on heating with potassium carbonate it gives a mixture of cyanide and cyanate. Heated with concentrated sulphuric acid it yields pure carbon monoxide; with dilute sulphuric acid it yields hydrocyanic acid. Its solution is oxidised by chlorine or bromine to potassium ferricyanide. For the action of nitric acid *see* SODIUM NITROPRUSSIDE *under* SODIUM COMPOUNDS. It is used in the manufacture of Prussian Blue and in calico printing. It is formed by the solution of iron in potassium cyanide solution in absence of air, or of a ferrous salt in the same solution, the latter being in excess. The chief commercial source of this compound is crude coal gas, from which it is prepared in two distinct ways: (1) From the gas before it enters the purifier (*see* GAS MANUFACTURE, p. 250); (2) from the spent hydrated oxide of iron used in some gasworks as the purifying agent. In this case the spent oxide, after a preliminary treatment for the removal of ammonia and sulphur, is mixed with quicklime and heated at 60° to 100° in closed vessels, where it loses ammonia. The product is extracted with water, and the solution of calcium ferrocyanide is treated with sufficient potassium chloride to give the sparingly soluble double salt $K_2CaFe(CN)_6$, which is filtered off, washed, and boiled with potassium carbonate. The solution of potassium ferrocyanide is then crystallised. POTASSIUM FERRICYANIDE, $K_3Fe(CN)_6$ (also called Red Prussiate of Potash), is a dark red solid, crystallising in prisms; heated in air, it gives potassium cyanide and ferric oxide, with loss of cyanogen; soluble in water. Its solution is decomposed by light, forming the ferrocyanide and a blue precipitate; its solution is used as an oxidising agent, being reduced to ferrocyanide, and as a test for iron. It is prepared by passing chlorine into a solution of potassium ferrocyanide, and crystallising till free from potassium chloride. POTASSIUM SULPHOCYANATE, KCNS (also called Potassium Thiocyanate), is a colourless, crystalline, deliquescent solid, very soluble in water, soluble in alcohol. It yields a blood red coloration with solutions of ferric salts. Heated with alkyl iodides, it gives alkyl sulphocyanates. With oxidising agents such as nitric acid, chlorine, etc., it yields a yellow solid of doubtful composition called pseudo-cyanogen sulphide, $C_3N_3S_3H$, which has been used as a dye under the name Canarine. It is prepared by warming a solution of potassium cyanide with sulphur; also by fusing together potassium ferrocyanide, potassium carbonate, and sulphur. The cold and powdered product is extracted by boiling with alcohol; from the alcoholic solution the salt crystallises out. POTASSIUM NITRITE, KNO_2, is a faintly yellow crystalline (prisms) solid; deliquescent; exceedingly soluble in water (dissolves in one-third its weight of water); solution is yellow and slightly alkaline; readily decomposed by acids, giving nitrous acid (*q.v.*) It is obtained by fusing potassium nitrate at a dull red heat, and gradually adding lead, extracting the fused mass with water, and purifying by recrystallisation. A purer product is obtained by passing the red fumes from nitric acid and arsenious oxide into a solution of pure caustic potash till nearly neutral; the nitrite can be crystallised by concentration to the requisite strength. POTASSIUM NITRATE, KNO_3 (also called Salpetre and Nitre), is a white solid crystallising in rhombic prisms; melts at 352°; very soluble in water (at 20°, 100 parts water dissolve 31·2 parts KNO_3). On heating above its melting point it loses oxygen, forming the nitrite, and at higher temperatures it loses nitrogen and forms a mixture of the oxides. It is reduced to ammonia by the action of the zinc-copper couple on its solution. Heated with oxidisable substances, it gives up oxygen to them; *e.g.* sulphur thrown into the fused salt burns brilliantly, so too carbon: $2KNO_3 + 2S = K_2SO_4 + SO_2 + N_2$. $4KNO_3 + 5C = 2K_2CO_3 + 3CO_2 + 2N_2$. *See also* POTASSIUM NITRITE *and* GUNPOWDER. It occurs naturally in rich soils, in most spring and river waters, as an efflorescence on the soil in many hot countries. Formerly the chief source of nitre was the natural product formed by nitrification (*q.v.*) in the soil about the drains of Indian villages. On the large scale it is made by double decomposition between potassium chloride and sodium nitrate. The diagram (fig. 2) shows the solubility of potassium nitrate and sodium chloride expressed in parts dissolved by 100 parts of water. Above 24° sodium chloride is the least soluble in water of any of the four salts mentioned. Below this temperature potassium nitrate is the least soluble. Hence, if hot and strong solutions of sodium nitrate and potassium chloride are mixed, sodium chloride will separate. Below about 24° potassium nitrate will separate; it does not separate pure, but is easily purified by recrystallising. Nitre is used in making gunpowder, in medicine (*e.g.* in asthma, when porous paper is soaked in the solution, dried, and ignited, and the fumes are inhaled), and

as a food preservative. *See also* NITRIC ACID *and* POTASSIUM SULPHIDES. The normal sulphide, K_2S, has not been obtained pure; crystals of K_2S5H_2O are obtained by evaporating the solution obtained by passing sulphuretted hydrogen to saturation into one half of a solution of caustic potash, and then adding the other half. Its solution does not keep, but forms polysulphides and potassium thiosulphate. LIVER OF SULPHUR is the name given to

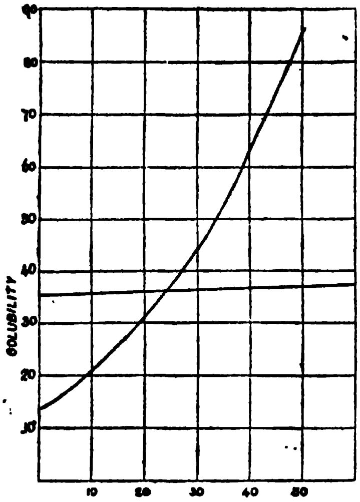

FIG. 2.—TEMPERATURE.

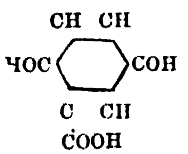
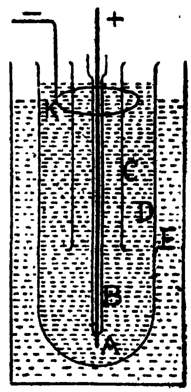
the mixture of sulphides, sulphate, and thiosulphate obtained by heating sulphur and potassium carbonate together. It is used in medicine as an ointment in some skin diseases. The HYDROSULPHIDE, KSH, is obtained by heating potassium in sulphuretted hydrogen, or by saturating a solution of caustic potash with sulphuretted hydrogen. *See* MERCAPTANS. POTASSIUM SULPHATE, K_2SO_4, crystallises in white rhombic pyramids; melts at 1,078°; soluble in water; at 15° 100 parts water dissolve 10·3 parts; insoluble in alcohol. It is used in medicine. It may be obtained by the action of sulphuric acid on the hydroxide, carbonate, or chloride; it is obtained in quantity from Kainite, $K_2SO_4 . MgSO_4 . MgCl_2 5H_2O$, by allowing it to deliquesce when the magnesium chloride goes into solution and the potassium sulphate is obtained by crystallising the residue. POTASSIUM PERSULPHATE, $K_2S_2O_8$, is a white solid which crystallises in tables or prisms; soluble in water (100 parts water dissolve 1·77 parts of the salt at 0°); the solution slowly decomposes on standing in the cold, but quickly on warming, with evolution of oxygen. On heating it begins to decompose at 100°: $K_2S_2O_8 = K_2SO_4 + SO_3 + O$. It is a slow but powerful oxidising agent; it liberates halogen from haloid salts; dissolves many metals, forming sulphates, and then changes the sulphate to peroxide in the case of those metals that form peroxides, *e.g.* silver gives Ag_2O_2, nickel gives Ni_2O_3. It oxidises ferrous sulphate to ferric sulphate; manganous sulphate to manganese dioxide; alcohol to aldehyde; salicylic acid to hydroquinone carboxylic acid,

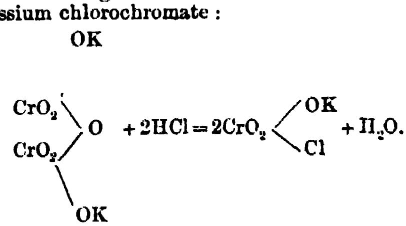


It is obtained by the electrolysis of a saturated solution of potassium sulphate in sulphuric acid of 1·2 to 1·3 specific gravity. The electrodes are of platinum wire: the anode A is sunk deep in the liquid and sealed into a glass tube B for the greater part of its length (high current density at anode): the kathode K is a ring of wire near the surface of the liquid. A wide glass tube C surrounding the anode carries the liberated oxygen to the surface of the liquid without its coming near the kathode. The electrolytic cell D must be cooled by standing in a vessel of cold water, E. The persulphate separates at the anode, and may be purified by adding it to hot water and allowing to cool when the salt crystallises out. Its formation may be represented thus: The negative ions of the acid sulphate travel to the anode, and these (*a*) decompose water, liberating oxygen and reproducing acid sulphate; (*b*) unite with one another to form the persulphate

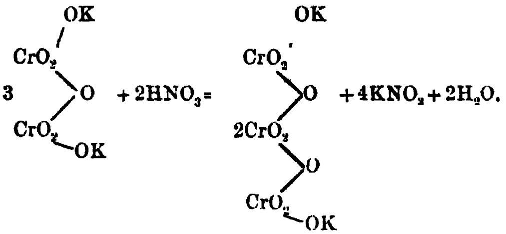


$$SO_2\left\langle{}^{\bar{O}K}_{O-}\right. + SO_2\left\langle{}^{OK}_{O-}\right. = SO_2\left\langle{}^{OKKO}_{O\text{——}O}\right\rangle SO_2.$$

POTASSIUM CHROMATE, K_2CrO_4, is a bright yellow crystalline solid, isomorphous with the sulphate; on heating it melts without decomposition; very soluble in water (100 parts water at 20° dissolve 62·94 parts of the salt); its solution is alkaline to litmus, and has very strong colouring power, one part of the salt colouring 400,000 parts of water; insoluble in alcohol. All acids convert the normal chromate to the dichromate, *e.g.* $2K_2CrO_4 + H_2SO_4 = K_2Cr_2O_7 + K_2SO_4 + H_2O$. It is used as an indicator (*q.v.*) in the estimation of silver. It is obtained by adding the requisite quantity of caustic potash to a solution of the dichromate, $K_2Cr_2O_7 + 2KOH = 2K_2CrO_4 + H_2O$. POTASSIUM DICHROMATE, $K_2Cr_2O_7$, is a red crystalline solid, and the crystals are anhydrous; soluble in water (100 parts water at 20° dissolve 13·8 parts of the salt); insoluble in alcohol; poisonous; on heating, it melts, and only decomposes at a very high temperature into the normal chromate, chromic oxide, and oxygen, $2K_2Cr_2O_7 = 2K_2CrO_4 + Cr_2O_3 + 3O$. Its solution has an acid reaction. Heated with sulphuric acid, the dichromate reacts thus: $K_2Cr_2O_7 + 4H_2SO_4 = K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3O$. This reaction often occurs in the cold, when the solution of dichromate is mixed with sulphuric acid in presence of a substance capable of uniting with the oxygen; hence the use of potassium dichromate in the "Bichromate" battery and in the volumetric estimation of iron, in the oxidation of alcohol to aldehyde, of anthracene to anthraquinone, etc. Heated with concentrated hydrochloric acid, the dichromate gives chlorine: $K_2Cr_2O_7 + 14HCl = 2KCl + 2CrCl_3 + 7H_2O + 3Cl_2$. Gentle warming with a less concentrated acid gives potassium chlorochromate:



Heated with nitric acid, it gives the tri- or tetra-chromate, according to the strength of the acid.



Pot. Trichromate.

When gelatine is dissolved in a solution of the dichromate and allowed to solidify again, it is acted on by light, and the dichromate is reduced to chromic oxide; on this fact is based the autotype process of reproducing photographs, etc. Potassium dichromate is made by roasting chrome iron ore, grinding the roasted product, mixing it with potassium carbonate and quicklime, and heating the mixture strongly with free access of air in a reverberatory furnace. $Cr_2O_3 + 2K_2CO_3 + 3O = 2K_2CrO_4 + 2\,CO_2 . Cr_2O_3 + 2CaO + 3O = 2CaCrO_4$. The mixture of potassium and calcium chromates is extracted with water, and sufficient potassium sulphate added to precipitate the calcium as sulphate. The clear liquid is now treated with the requisite amount of diluted sulphuric acid, to convert all the chromate to dichromate, when the latter, being less soluble than the former, largely crystallises out. It is nearly pure. POTASSIUM COBALTINITRITE, $K_3Co(NO_2)_6$, is a yellow, finely divided crystalline solid, sparingly soluble in water. It may be formed by adding potassium nitrite to a solution of cobalt nitrate acidified with acetic acid. As the corresponding sodium salt is very soluble, it may be prepared first as just mentioned, using sodium nitrite in place of potassium nitrite, and then the potassium salt may be made from it by precipitation. The formation of potassium cobaltinitrite in this way serves as a test for potassium, which is far more delicate than platinic chloride. Nickel does not form a corresponding salt; its formation serves to distinguish between cobalt and nickel. For the following compounds, CHLOROPLATINATE, *etc.*, PERMANGANATE, *etc.*, *and* SILICOFLUORIDE, *see under* PLATINUM, MANGANESE, *and* SILICON COMPOUNDS *respectively*.

Potato (*Botany*). The underground stem tubers of the plant *Solanum tuberosum* (order, *Solanaceæ*) constitute the well known potatoes.

Potato Stone (*Geol.*) Geodes with a rough exterior which bears some resemblance in texture, and even in colour and size, to the vegetable from which the name is taken. They occur chiefly in the "Dolomitic Conglomerate" (which is a breccia of Upper New Red age) near Bristol.

Potboard (*Carp. and Join.*) The shelf under the drawers of a dresser.

Potboiler (*Art*). A work of art of little merit produced to fill a popular demand.

Potcher (*Paper Manufac.*) A machine similar in construction to the "breaker," used for breaking and bleaching pulp.

Potent (*Her.*) An obsolete word signifying a crutch. A field covered with small figures resembling a cross without the upper arm is called potent. Like vair, the tinctures are argent and azure alternately. *See* HERALDRY.

Potential Difference (*Elect.*) The difference of potential between two points is equal to the amount of work which must be done on a positive unit of electricity in order to bring it from one point to the other. In practice it is usually measured in VOLTS (*q.v.*) In the case of a battery, dynamo, etc., the potential difference at the terminals is that portion of the total electromotive force which is available for sending a current round any circuit external to the source itself.

Potential, Electrical. The work which must be done (against electrical forces) on a unit positive charge, in order to bring it up to a given point from an infinite distance (or from a place at which the potential is zero) is termed the Electrical Potential at that point. The potential V, due to a charge Q, at a distance r from the charge, is $V = \frac{Q}{r}$.

Potential Energy. The energy which a body possesses in virtue of its position, chemical constitution, or circumstances other than its state of motion. *Cf.* KINETIC ENERGY.

Potential Gradient (*Elect.*) The ratio between the difference of potential at two points in a conductor to the distance between the points measured along the conductor.

Potential, Magnetic. The work which must be done (against magnetic forces) in order to bring a unit positive pole up to a given point from an infinite distance, or from a place where the potential is zero, is termed the Magnetic Potential at that point.

Potentiometer (*Elect.*) An instrument for the comparison of electromotive forces by balancing them against the potential difference between two points in a conductor of considerable resistance, through which a steady current is flowing.

Pot Metal (*Met.*) An alloy of copper and lead, with sometimes tin, zinc, etc., added. It is occasionally used instead of brass in inferior work.

Pot-Pourri (*Music*). A collection or medley of musical tunes.

Pot Sleeper (*Civil Eng.*) A CHAIR (*q.v.*) cast on a broad base instead of being fixed to a wooden sleeper; used where wood is liable to rapid decay or destruction by white ants, etc.

Pott (*Paper*). Writing paper, 15 by 12½ in. Printing paper, 15½ by 12½ in.

Potter's Wheel (*Pottery Manufac.*) A vertical shaft with a flat circular head about 8 in. in diameter, upon which, while rotating at greater or less speed, such circular articles as cups, bowls, flower pots, etc., are made by the "Thrower."

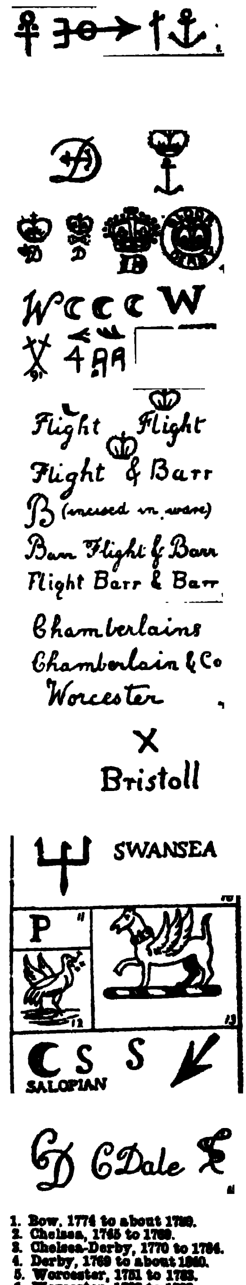
Pottery and Porcelain. (1) *Modern Methods of Manufacture.* (2) *History.*

(1) MODERN METHODS OF MANUFACTURE: Although generally spoken of in the same connection, pottery and porcelain are not synonymous terms. The generic term "Pottery" includes porcelain, terracotta, earthenware, and, in fact, any manufactured article composed of more or less vitrified clay. "POTTERY," properly so called, is inferior to porcelain. It is composed of clays and earths, either simple or admixed, which, after being submitted to the greater or less heat of the kiln, remain of a clay nature—porous, opaque, and only slightly resonant. "PORCELAIN" is more highly refined, and is composed of higher quality clays and earths, silicates, alkalies, phosphates, and alumina. After submission to a

sufficient heat in the kiln, its nature becomes changed, and it is no longer clay; it is highly vitrified, non-porous, semi-translucent, and highly resonant when struck. Porcelain is subdivided into two classes: hard paste and soft paste. "HARD PASTE" is, generally speaking, an admixture of natural materials, such as "kaolin" (a silicate of alumina) and "petuntse," a similar material, but less decomposed, and containing more alkali and more lime. After thorough amalgamation, the article manufactured from the resulting paste is burnt at such a temperature as leaves it only hardened and porous. It is then dipped in the glaze mixture, which is composed largely of felspar, and submitted to a sufficiently high temperature to melt the glaze, which becomes partially absorbed by the "body," rendering it translucent and non-porous, and giving a perfect gloss to its surface. SOFT PASTE is more artificial in its composition than hard paste, and is manufactured on a different principle. Kaolin and petuntse are the chief ingredients, as in hard paste, but to them is added calcined bone and sometimes felspar. The articles manufactured from soft paste are first submitted to the greatest heat, rendering them at the first burning non-porous, translucent, and resonant. They are then dipped in the glaze mixture, which is composed generally of a glass flux, kaolin, and carbonate of lime, ground finely together, and afterwards submitted to a temperature much lower than the first or bisque heat, but sufficient to melt the glaze upon the surface of the ware, the glaze in soft paste remaining upon the surface of the ware, and not being absorbed into it as in hard paste. Apart from the difference in the constituents, the manufacture of pottery and porcelain is almost identical. After the raw materials are reduced to fine creamy consistency either by grinding or by blunging (cutting up of clays in water by rotating knives), they are mixed in their proper proportions, and the resulting paste is then either used in "slip" or creamy state, or in clay, to obtain which a sufficient amount of water is squeezed from the "slip" in presses, or evaporated from it by heat, so rendering it stiff and plastic. The clay is now passed to the "thrower," who makes articles upon the potter's wheel, or to the "presser," who forms them by pressing it upon proper moulds. The "slip," on the other hand, goes to the caster, who forms the required articles by casting; that is, by pouring the "slip" into the moulds. In each case the moulds are made of plaster of paris or gypsum, and are very porous, rapidly absorbing water from the clay or slip placed in contact with them. In the case of casting, the absorption of the plaster mould causes a coating of clay to adhere all over the inside of the mould and take its exact shape, and when this is sufficiently thick the potter pours away the remaining slip from the mould, and in due course the coating becomes sufficiently hard for the mould to be opened, and the clay which has formed inside to be taken out and finished. Articles "thrown" upon the wheel are generally, and while the clay is still moist, pressed into moulds, to ensure uniformity of size and weight. After they have become sufficiently hard to handle, they are removed from the moulds, and are finished by the "turner" upon the lathe. In the case of "handled" pieces, the handle, after being "pressed" in a mould of the required shape, is affixed by dipping the part which is to come in contact with the body in "slip," and pressing it into the the correct position. The manufacture of elaborate figures or VASES is done by casting, each part being formed in a separate mould, and the pieces joined together by the skilled potter. Some figures and vases require as many as from ten to forty moulds for the manufacture of the one perfect piece. An important consideration in the manufacture of pottery and porcelain is the contraction that takes place until the article has reached the maximum heat in the bisque oven. The contraction is threefold, and is due (1) to the evaporation or expulsion of the added water; (2) to the driving off of the chemical water; (3) to the vitrification or drawing closer together of the particles of which the paste is composed. Clay articles when completed and thoroughly dried are placed in SEGGARS or fireclay boxes, plates, saucers, and flat ware being bedded in ground flint, the bed being made by a mould the exact shape of the article to be fixed in it. The seggars containing the clay ware are stacked in the bisque oven, which is bricked up. The fires are lit, and the heat is slowly raised to the required temperature. After cooling, the kiln is opened and the ware taken out, the superfluous ground flint removed by scouring, and the ware sent to the dipping house, where it is dipped in the required glaze. This is of about the consistency of thin cream. The articles are again placed in seggars (glazed), and stacked in the glost or glazing oven, which is generally of similar construction to the bisque oven. Except in the case of hard paste, the heat now necessary is much less than that required for bisque. Upon removal of the glazed ware from the glost oven, it is sorted and is then ready to be decorated. In the case of under glaze decorations, they are applied to the *bisque ware*, the glaze being super-imposed, the melting of the glaze allowing the colours to show through. Reds made from oxides of iron and pinks and purples made from gold will not stand the great heat of the glost oven, and therefore cannot be used as under glaze colours. The glazed ware is now sent to the decorators for the requisite ornamentation. If it is to be painted, it goes first to the painter; if it is to have a coloured ground, to the ground layer (*q.v.*); or if a printed pattern, to the printer. To produce the best results, the painting is usually executed in two and sometimes even three or more stages, the ware being burnt in the enamel kiln (*q.v.*) after each painting. The first coat is called the "washing in," and the subsequent paintings the "finishing." The colours used are made from mineral salts, the following being the main colouring agents: Blues are made from cobalt; blacks from cobalt, manganese and iron in combination; turquoise from oxide of copper; greens from oxide of chrome and from oxide of copper; browns and reds from the chromates and oxides of iron; yellow from lead, tin, and antimony in combination; enamel pinks, rose colours, purples, rubies, and crimsons from gold; under glaze pink from oxides of tin and chrome in combination. Metallic gold, which is laid on as required by the gilder, is fired at the same heat as the painting in the enamel kiln. Gold is prepared as follows: Pure grain gold is obtained, and to it is added a certain proportion of metallic mercury. The mercury forms an amalgam with the gold, destroying its ductility; a little flux is added to ensure its adhesion to the ware, and the mixture is finely ground upon a mill. It is then mixed with a suitable medium, and laid upon the ware with a paint brush; upon being subjected to the heat of the kiln, the mercury becomes volatilised, leaving the pure gold adhering to the ware. The gold is afterwards burnished by being rubbed with an agate or hematite, commonly called bloodstone.

(2) HISTORY: *Ancient Pottery—Egyptian, Greek, Roman.* The history of pottery is practically the history of man. There is no nation in the world in which use has not been made of clay for the formation of vessels for domestic or other purposes. Pottery, with more or less pronounced attempts at decorative ornamentation, has steadily followed the path of civilisation, and amongst historic nations the earliest pottery known is that of Egypt, dating some three thousand years before the Christian era. These relics of the earliest known civilisation have definite characteristics in harmony with the ruins among which they have been found; improvement and development were gradual and persistent, and the later progress of one nation is coeval with the germ of art in another. In the course of a few centuries Egyptians discovered the art of glazing their wares. Subsequent progress is evident as regards style and refinement of form some centuries later, until there is a new birth in another and a neighbouring country, influenced by the developments of a couple of thousand years in the older nation. Thus we see in the first Greek archaic pottery (dating about 700 B.C.) traces of Egyptian civilisation and motives of Egyptian character. From the date of the earliest Greek wares progress becomes much more rapid as civilisation advances, and in a period of about three hundred years we arrive at the most sublime period of Greek Keramic Art. Egyptian character has gradually died away, and has given place to the vigorous indigenous growth which has been grafted upon it. The Greek pottery of this period (about 400 B.C.) is marvellous in its perfection of form and in the care exhibited in the execution of the ornamental delineations. Figures of the most refined and beautiful character were also produced. As from the Egyptian to the Greek, so from the Greek to the Roman; but it cannot be said that the wonderful progress was continued or even the high level maintained. Pottery is essentially one of the arts of peace, and the Romans were not a peaceful people. Roman pottery never attained the perfection of the Greek; the materials were coarser, the forms less refined, and the ideas of decoration were more inclined to revert to the Archaic than to improve upon the Etruscan. Not only were the Romans unable to hand down a pure classic style of their own to future generations, but by their lust of conquest they brought about the extinction of, and dealt the death blow to, the long line of the most sublime creations in Keramic history. PORCELAIN emanates from the Celestial Empire, and was first made about one hundred years B.C. The finest Chinese porcelain was made during the fourteenth, fifteenth, and sixteenth centuries. Porcelain was probably not made in Europe before the end of the seventeenth or the beginning of the eighteenth century. The first porcelain manufactured in England was produced just before the middle of the eighteenth century (about 1740). The chief European manufactories of porcelain, dating from the earliest days, are: Dresden (Meissen), the national manufactory of Saxony, established about 1706, and still flourishing; Capo di Monte (Naples), established 1736, abandoned 1821; Buen Retiro (Madrid), established same time, abandoned 1812; Lille, established 1711, abandoned about 1800; Tournay, established 1750, still carried on; Chantilly, established 1725, abandoned about 1800; St. Cloud, established about 1696, destroyed by fire 1773; Sèvres (originated at St. Cloud), the national manufactory of France, and still carried on (the finest Sèvres porcelain was manufactured about the middle of the eighteenth century); Berlin, established 1751, the national manufactory of Germany, and still flourishing; Vienna, established 1718, practically ceased working about 1860. There have been, of course, many other less important factories, and there are to-day great numbers in France, Germany, and Austria. Pottery has been, and probably is still, made in every country on the globe, and it is difficult to specify places; but mention may be made of Delft in Holland, Rouen (France), Urbino and Faenza (Italy), as producing as early as the end of the fifteenth century exceedingly fine decorated pottery. In England pottery and good earthenwares were made at a very early date, but porcelain is only traceable to the first half of the eighteenth century. The first manufactory of any note was probably that established at Stratford-le-Bow, near London, the productions being always known as "Bow" china. This manufactory only lasted about thirty years, the whole concern being purchased about the year 1770 by William Duesbury, of Derby. A porcelain manufactory was established at Chelsea a little later, and became very famous for its fine productions, large quantities of figures and fine vases being made there. This manufactory was also purchased by Duesbury about the same time or a little earlier (1769) than the purchase of Bow. The next establishment for the manufacture of porcelain was that at Worcester in 1751. It is probable that the productions of no English porcelain manufactory equalled those of Worcester for refined taste and general excellence. The manufactory has been continued to the present day, and it is the only porcelain manufactory in existence in England which can show an unbroken descent from so early a date as 1751. The manufactory at Derby, established in 1756, was continued until the year 1849, and about the

ENGLISH POTTERY MARKS.



1. Bow, 1774 to about 1780.
2. Chelsea, 1745 to 1769.
3. Chelsea-Derby, 1770 to 1784.
4. Derby, 1769 to about 1840.
5. Worcester, 1751 to 1783.
6. Worcester, 1783 to 1792.
   Worcester, 1793 to 1807.
   Worcester, 1793 to 1812.
   Worcester, 1793 to 1812.
   Worcester, 1813 to 1840.
7. Worcester (Chamberlains), 1786 to 1840.
8. Plymouth, 1768 to 1774.
9. Bristol, 1768 to 1782.
10. Swansea, about 1800 to about 1830.
11. Pennington, Liverpool.
12. Herculaneum, Liverpool.
13. Rockingham Porcelain, about 1823.
14. Caughley (Salopian), 1772 to 1799.
15. Coalbrook Dale (Coalport), 1780 to about 1840.

same period were founded factories at Caughley (Salopian), Coalport, and Lowestoft; also the factories at Plymouth and Bristol, and both pottery and porcelain were made in Liverpool. The celebrated Wedgwood ware was also first produced about the same period (1762). At later dates the manufacture of pottery and porcelain extended very considerably, especially in the "Pottery" district of North Staffordshire, there being many factories at Stoke-on-Trent, Hanley, Burslem, Longton, Shelton, etc. Factories which, however, existed for only a comparatively short space of time were carried on at Nantgarw and Swansea, in Wales. The Rockingham manufactory at Swinton also produced some fine porcelain. It is probable that at the present time *pottery* in one form or another is made in nearly every county in England. The manufacture of *porcelain* is much more restricted, being practically confined to Worcester, Derby, Coalport, and the Staffordshire "Potteries." W. M. B.

Pot Valve (*Eng.*) A valve whose cover consists of a short tube closed at the top; occasionally used as a safety valve.

Pouncing (*Dec.*) The method of transferring a design done on paper to a panel, ceiling, wall, or other surface on which it is to be finally executed. It consists in perforating the outline of the design with a needle set in a handle, or, better still, by means of a small implement used by dressmakers, and called a "tracer." The paper pattern is then fixed in position on the wall, etc., by means of needle points, and a pouncer formed of a linen bag, and containing charcoal or fine coloured chalk, is dabbed over the lines, a portion passing through the small holes and leaving the pattern on the surface beneath. When the design is of a complicated character, it is often found convenient to use two or more different coloured chalks, so as to distinguish the different parts.

Pound. *See* WEIGHTS AND MEASURES.

Poundal (*Mech.*) The unit of force in the English system; it is the force which, if it act on a mass of 1 lb., produces in it an acceleration of 1 ft. per second per second.

Pound Degree (*Eng.*) The unit of heat commonly used by English engineers; it is the amount of heat necessary to raise 1 lb. of water 1° F.

Pouring (*Foundry*). The process of filling a mould with melted metal.

Pouring Gate (*Foundry*). The INGATE by which melted metal enters a mould. *See* GATE.

Poussé (*Music*). The upstroke of the bow.

Powder of Algaroth (*Chem.*) An old name for antimony oxychloride, so called from a physician, Algarotus, who employed it in medicine. It is not used now.

Power (*Phys., Eng., etc.*) The amount of work done (or energy supplied) in unit time. *See* HORSE POWER, JOULE, *and* WATT.

——, Alternating Current (*Elect. Eng.*) The power developed by an alternating current is equal to the product of the virtual current, virtual voltage, and the cosine of their phase difference. *See* POWER FACTOR.

——, Electrical. *See* WATT.

Power Factor (*Elect. Eng.*) The ratio of the true power in an alternating current circuit to the apparent power obtained by multiplying together the virtual current C and virtual voltage V. In simple cases the power is equal to CV Cos ϕ, where ϕ is the angle of lag or phase difference between the E.M.F. and the current in the circuit.

Power House (*Elect. Eng., etc.*) The building or central station containing the engines, boilers, dynamos, etc., for supplying current.

Practical Units (*Elect.*) *See* AMPÈRE, VOLT, OHM, *and* UNITS, ELECTRICAL.

Pralltriller (*Music*). *See* MORDENTE.

Prase (*Min.*) A translucent leek-green variety of quartz or chalcedony. It is used as an ornamental stone.

Prasodidymium (*Chem.*) *See* DIDYMIUM.

P. R. B. (*Art*). *See* PRE-RAPHAELITE BROTHERHOOD.

Pre-Admission (*Eng.*) The admission of fresh steam to a cylinder shortly before the end of a stroke.

Pre-Cambrian Rocks (*Geol.*) The series of fossiliferous rocks, which are next older than the Ordovician Rocks, forms the lowest member of the Protozoic System. As the Cambrian Rocks contain representatives of almost all the known groups of invertebrata, they were probably formed long after the Dawn of Life upon the Earth. Three subdivisions of the Cambrian Rocks are recognised. The lowest, sometimes called the Taconic System, contains the trilobites belonging to the *Olenellus* group; the next above yields trilobites of the *Paradoxides* type; and the highest is characterised by forms of trilobites allied to *Olenus*. In the north-west of Scotland the highest member of the Cambrian Rocks is the Durness Limestone. Below the base of the Cambrian Rocks, and therefore of older date than any fossils yet known with certainty, there occur various other rocks, which are those referred to. In the Longmynd, on the border of Wales, the base of the Cambrian Rocks at Caer Caradoc lies upon some ancient volcanic rocks known as the URICONIAN ROCKS, and in another place upon some very ancient sediments. In Anglesea, again, a Pre-Cambrian set of volcanic rocks, the Bangor Beds, underlies the base of the Cambrian Rocks. At Barmouth a thick series of greywackés, the Harlech Beds, usually classed with the Cambrians, occurs beneath them. In the north-west of Scotland an ancient set of rocks, the TORRIDONIANS, which were formed under desert conditions, occurs between the Lewisian Gneiss and the lowest member of the Cambrian Rocks; and if they are not faulted into that position, they must also be truly of Pre-Cambrian age. Elsewhere in Scotland the rocks which are known with certainty to be Pre-Cambrian are either part of the Lewisian Gneiss or else some very ancient sediments, out of which, it is believed, the gneisses themselves have been formed.

Precentor (*Music*). A cathedral official who directs the choir and the musical portions of the service.

Precession of the Equinoxes. A gradual movement of the First Points of Aries and of Libra along the ecliptic, at the rate of about 50 seconds per year. This is due to the fact that the earth's axis is not fixed in space, but is slowly describing a conical figure, like a spinning top does when it "reels" without falling over.

Précieux (*Art*). The term applied to works of art which exhibit careful execution with a fine and masterly touch.

Precious Coral. *See* CORAL.

Precious Stones and Gems. To the ancients a gem was any stone which was beautifully coloured, rare, or of sufficient hardness to use for seal engraving. The term is now used for a stone which in one

small piece exhibits fine colour, fire, or lustre, and which is hard enough to take a good polish. Precious stones are those which possess similar properties in an inferior degree. The nomenclature is very complex, and those minerals to which the ancients applied a certain name are in but few cases the same as those for which we now use the name. In popular language many totally different minerals are known by the same name; and lapidaries name a gem stone rather by its colour than by its composition, distinguishing between different species by calling the more valuable Oriental and the less valuable Occidental. Often, too, they use some adjective derived from the locality in which the stone occurs to indicate the less or more valuable gems, *e.g.* yellow Quartz they call Brazilian Topaz to distinguish it from true Topaz; and the yellow variety of Corundum, which is more valuable on account of rarity, hardness, and brilliancy than the true Topaz they call Oriental Topaz. Another confusion arises from the popular impression that many gems which are of the same mineralogical species are different, *e.g.* Ruby and Sapphire, which are both varieties of Corundum.

LIST I.—COMMERCIAL AND POPULAR NAMES.—In this list, against the popular name of the gem, is given a note of the various minerals which may occur commercially under that name.

ADAMANT	Diamond.	
	Corundum in part.	
ALABASTER	of the Ancients	= a stalagmitic variety of Calcite.
	massive Gypsum.	
ALMANDINE	one of the Precious Garnets.	
	an old name for violet Spinel.	
AMETHYST	true	= violet Quartz.
	Oriental	= violet Corundum.
	false	= violet Fluorspar.
	in part the Hyacinth of the ancients.	
AVENTURINE	a variety of Quartz with spangles of Mica.	
	a variety of Orthoclase with spangles of Mica.	
	a variety of Albite with spangles of Mica.	
	a variety of Oligoclase with spangles of Mica.	
BERYL	*See* LIST II.	
CAT'S EYE	Quartz with parallel fibres of Asbestos.	
	Chrysoberyl cut *en cabochon.*	
	a variety of Microcline.	
CHRYSOBERYL	true	
	of the Ancients	yellow green Beryl in part.
		Chrysoprase in part.
CHRYSOLITE or PERIDOT	true, a variety of Olivine.	
	Oriental	= yellow green Corundum.
	of the Ancients	= Topaz.
	Brazilian	= yellow green Tourmaline.
	Peridot of Ceylon	= yellow green Tourmaline.
CHRYSOPRASE	true, a green variety of Chalcedony.	
	of the Ancients	= Emerald.
		Chrysoberyl.
DIAMOND	true.	
	Occidental	= Rock Crystal, a variety of Quartz.
EMERALD	true, green Beryl.	
	false	= green Fluor.
	Oriental	= olive green Corundum.
	Brazilian	= green Tourmaline.
GARNET	*See* LIST II.	
HYACINTH or JACINTH	true, a red variety of Zircon.	
	Oriental	= reddish brown Corundum.
	of Compostella	= Quartz stained red by clay.
	Vesuvian	= Idocrase.
MOONSTONE	a variety of Microcline, Albite, or Oligoclase.	
	of the Ancients	= Selinite, a variety of Gypsum.
PERIDOT	*See* CHRYSOLITE.	
RUBY	true or Oriental	= Corundum of the ruby colour.
	false	= red Fluor.
	Bohemian	= rose Quartz.
	Balas Ruby	= red Spinel.
	Elie Ruby, Rock Ruby	= Pyrope Garnet.
	Brazilian	= yellow Topaz turned red by heat.
		red Tourmaline.

SAPPHIRE	true or Oriental . .	blue Corundum (= Telesia).
	false	blue Fluor. blue Quartz.
	Saphir d'Eau Water Sapphire . .	= blue Iolite.
	of the Ancients in part .	= Lapis Lazuli.
	Brazilian	= blue Topaz. Indicolite (blue Tourmaline).
	Sapphire of de Saussure.	= Cyanite.
SPINEL	*See* LIST II.	
TOPAZ	true	
	false	= yellow Fluor. Citrine (yellow Quartz).
	yellow Bohemian	= Citrine (yellow Quartz).
	smoky	= Smoky Quartz.
	Oriental	= reddish yellow Corundum.
	of Ancients	= Olivine in part.
TURQUOISE	true.	
	of Ancients	= Lapis Lazuli in part.

LIST II.—NAMES OF MINERALOGICAL SPECIES.—In the following list of gems and precious stones the names as commonly used are given under the *mineralogical species* to which the stones belong; those marked with an asterisk may more properly be considered gems.

*DIAMOND = Adamant of the Ancients.

FLUORSPAR: the violet variety . = False Amethyst.
- „ green „ . = „ Emerald.
- „ red „ . = „ Ruby.
- „ blue „ . = „ Sapphire.
- „ yellow „ . = „ Topaz.

QUARTZ.—Varieties: Rock Crystal . = Occidental Diamond = Whitestone.
- Stained red by clay = Hyacinth Compostella.
- Star Quartz.
- *Amethyst: this was in part the Hyacinth of the Ancients.
- Rose Quartz . . = Bohemian Ruby.
- *Citrine . . . = Yellow Topaz = False Topaz = Bohemian Topaz.
- *Smoky Quartz. . = Cairngorm = Smoky Topaz. Morion is a very dark variety.
- Blue . . . . = Sapphire.
- Aventurine.
- Sagenitic: (*a*) containing Rutile = Venus' or Thetis' Hair Stone or Flêches d'Amour.
- Cat's Eye. Tiger's Eye. Chalcedony.
- Carnelian . . . = Sard; finer varieties = Oriental Carnelian; softer and yellowish red varieties = Occidental Carnelian.
- Chrysoprase . . = Chrysoberyl of the Ancients.
- Prase . . . . = A leek green variety.
- Plasma, from πλάσμα, is used for intaglios.
- Bloodstone . . = Heliotrope.
- Agate: (*a*) Banded . = Scotch Pebble; (*b*) Fortification; (*c*) Moss Agate = Mocha Stone.
- Onyx, naturally bands of different degrees of porosity. Only black and white artificially.
- Sardonyx = bands of Sard (Carnelian) and white Chalcedony.
- Jasper.

OPAL.—Varieties are: Precious Opal, Fire Opal, Australian Opal, Cacholong (a milky white variety), and Girasol, white with red reflections in the sun.

CORUNDUM: anciently Corivendum, sometimes called Adamant.

Varieties in colour:
- pigeon's blood . = *Ruby (also called Oriental or True Ruby).
- magenta . . = Barklyite.
- reddish brown . = Oriental Hyacinth.
- light brown . = Adamantine Spar.
- violet . . = Oriental Amethyst.
- with pearly reflections = Chatoyant / Opalescent Sapphire.
- white .
- reddish yellow = Oriental Topaz.
- colourless
- yellow green = Oriental Peridot or Oriental Chrysolite.
- olive green = Oriental Emerald.
- blue . . = *Sapphire (also called Oriental Sapphire and Telesia). Sub-variety: Asteriated or Star Sapphire or Star Stone. Sapphire was in part the Hyacinth of the Ancients.
- different colours Montana Sapphire.
- colourless, with reddish or bluish reflections = Girasol Sapphire.

SPINEL: red . . . . = *Balas Ruby (Rubicelle or Ruby Spinel).
pale blue . . . . . . = Akcrite.
violet . . . . = Almandine of old writers.
*CHRYSOBERYL.—Varieties: Alexandrite, dark emerald green, red by transmitted light, strongly phosphorescent.
Cat's Eye . = Cut *en cabochon.*
Cymophane, an opalescent variety.
Chrysoberyl represented in part the Chrysoprase of the Ancients.
CALCITE.—Varieties: Mexican Onyx, stalactitic, from Mexico.
Alabaster of the Ancients was a stalactitic or stalagmitic calcite.
Lumachelle or Fire Marble.
MALACHITE.
ORTHOCLASE: Adularia, a transparent and pearly variety.
Sunstone or Aventurine Felspar containing spangles of Mica.
MICROCLINE: Moonstone, with a pale pearly lustre.
Amazonstone, bright green.
Cat's Eye, with a banded flash of light.
ALBITE: Aventurine (Sunstone).
Moonstone.
OLIGOCLASE: Sunstone.
Moonstone.
LABRADORITE.
PYROXENE: Diopside, a green transparent variety from Ala in Piedmont.
CROCIDOLITE.
*BERYL: pale green . = *Beryl of jewellers.
blue green . = Aquamarine.
yellow green . = Golden Beryl, the Chrysoberyl of the Ancients.
rich green . = *Emerald, formerly Smaragd; the Chrysoprase of the Ancients.
*IOLITE . = *Cordierite = Dichroite.
Saphir d'Eau or Water Sapphire is a blue variety.
LAPIS LAZULI . . . . . = Sapphire of Ancients in part. Turquoise of Ancients in part.
GARNET: I. Aluminium Garnet . = Grossularite (*Essonite).
*Pyrope (Precious Garnet, Ruby, Bohemian Garnet, or Rock Ruby).
*Almandine = Precious Garnet in part (*en cabochon* = Carbuncle).
II. Iron Garnet . . = Topazolite, a yellow variety.
Dermantoid, an emerald green variety.
III. Chromium Garnet . = Uvarovite, green.
OLIVINE: *Chrysolite (Peridot, the Topaz of the Ancients) is a yellow green transparent variety.
Chrysopal is an opalescent variety.
DIOPTASE.
IDOCRASE . . . . . = Vesuvianite = Vesuvian Hyacinth. Cyprine is a pale blue variety.
ZIRCON: red . . . . = *Hyacinth or Jacinth (the Legiero of Aaron's Breastplate probably).
colourless or smoky . = Jargoon.
olive green . . . = Beccarite.
*TOPAZ . . . . . . = Chrysolite of the Ancients; formerly also called Physalite or Pyrophysalith.
colours: pale yellow . . = Saxon Topaz (when turned red by heat it is called Brazilian Ruby).
more varied yellows . . = Mexican Topaz.
colourless . . . . . = Gouttes d'Eau.
blue . . . . . . = Brazilian Sapphire.
ANDALUSITE.
*CYANITE . . . . Sapphire of de Saussure; also called Sapparc.
ZOISITE: a pink variety is called Thulite.
PREHNITE: cut *en cabochon.*
*TOURMALINE: colours: dark blue . . = Indicolite or Brazilian Sapphire.
yellow green . = Peridot of Ceylon or Brazilian Chrysolite.
pink . . = *Rubellite or Red Schorl.
red . . . . = Brazilian Ruby.
green . . = Brazilian Emerald.
colourless . . = Achroite.
SERPENTINE.—Varieties: Precious Serpentine and Picrolite (fibrous).
SPHENE: Ligurite, a green variety from Liguria.
TURQUOISE . . . . = Callais of Pliny.
GYPSUM: the variety Selenite probably was the Moonstone of the Ancients; massive = Alabaster.
AMBER: Copalite is a fossil Amber.
JET.

List III.—The following table gives the crystallographic system, chemical composition, and principal physical characteristics of the species enumerated above:

	Crystallographic System.	Specific Gravity.	Hardness.	Refractive Index.	Chemical Formula.
Diamond	Cubic	3·5—3·6	10·0	2·439	C
Fluorspar	Cubic	3·017—3·188	4·0	1·434	CaF_2
Quartz	Rhombohedral	2·5—2·8	7·0	1·548	SiO_2
Opal	(Amorphous)	1·9—2·3	5·5—6·5		$SiO_2 . NH_2O$
Corundum	Rhombohedral	3·93—4·08	9·0	1·794	Al_2O_3
Spinel	Cubic	3·52—3·95	7·5—8·0		$MgO . Al_2O_3$
Chrysoberyl	Orthorhombic	3·68—3·75	8·5	1·76	$BeO . Al_2O_3$
Calcite	Rhombohedral	2·69—2·75	3·0	1·654	$CaCO_3$
Malachite	Monosymmetric	3·71—4·01	3·5—4·0		$2CuO . CO_2 . H_2O$
Orthoclase	Monosymmetric	2·53—2·59	6·0	1·53—1·76	$K_2O . Al_2O_3 . 6SiO_2$
Microcline	Triclinic	2·44	6·0		$K_2O . Al_2O_3 . 6SiO_2$
Albite	Triclinic	2·54—2·64	6·0—6·5		$Na_2O . Al_2O_3 . 6SiO_2$
Oligoclase	Triclinic	2·63—2·74	6·0		$3(Na_2O . Al_2O_3 . 6SiO$
Labradorite	Triclinic	2·67—2·76	6·0		$Na_2O . Al_2O_3 . 6SiO_2$
Pyroxene	Monosymmetric	3·2—3·4	5—6	1·680	$CaO(Fe,Mg)O . 2Si$
Crocidolite	(Fibrous)	3·2—3·3	4·0—4·5		$NaFe(SiO_3)_2 . FeSiO_3$
Beryl	Hexagonal	2·67—2·75	7·5—8·0	1·585	$3BeO . Al_2O_3 . 6SiO_2$
Iolite	Orthorhombic	2·60—2·72	7·0—7·5	1·544	$H_2O . 4(MgFeO) . 4Al_2O_3 . 10SiO_2$
Lapis Lazuli	Cubic	2·38—2·45	5·0—5·5		$Na_4(NaS_3 . Al)Al_2Si_3O_{12}$
Garnet—					
I. Aluminium:					
(*a*) Grossularite	Cubic	3·44—3·62	6·5—7·0		$6CaO . 3SiO_2 + 2Al_2O_3 . 3SiO_2$
(*b*) Pyrope	Cubic	3·70—3·78	6·5—7·5	1·792	$6MgO . 3SiO_2 + 2Al_2O_3 . 3SiO_2$
(*c*) Almandine	Cubic	3·95—4·29	7·0—7·5		$6FeO . 3SiO_2 + 2Al_2O_3 . 3SiO_2$
II. Iron:					
(*a*) Topazolite (*b*) Dermantoid	Cubic	3·65—3·85	7·0		$6CaO . 3SiO_2 + 2Fe_2O_3 . 3SiO_2$
III. Chromium:					
(*a*) Uvarovite	Cubic	3·42	7·5—8·0		$6CaO . 3SiO_2 + 2Cr_2O_3 . 3SiO_2$
Olivine	Orthorhombic	3·3—3·44	6·5—7·0	1·660	$2(MgFe)O . SiO_2$
Dioptase	Rhombohedral	3·27—3·35	5·0	1·667	$H_2O . CuO . SiO_2$
Idocrase	Tetragonal	3·35—3·45	6·5		$? H(OH)_2Ca_{12} . (AlFe)_6(SiO_4)_{10}$
Zircon	Tetragonal	4·0—4·7	7·5	1·961	$ZrO . SiO_3$
Topaz	Orthorhombic	3·4—3·6	8·0	1·627	$[Al(O,F_2)]AlSiO_4$
Andalusite	Orthorhombic	3·1—3·2	7·5	1·624	$Al_2O_3 . SiO_2$
Cyanite	Triclinic	3·58—3·68	5—6		$Al_2O_3 . SiO_2$
Zoisite	Orthorhombic	3·28—3·35	6—7		$4CaO . 3Al_2O_3 . 6SiO_2 . H_2O$
Prehnite	Orthorhombic	2·92—3·01	6·0—7·0		$H_2Ca_2Al_2Si_3O_{12}$
Tourmaline	Rhombohedral	3·0—3·3	7·0—7·5	1·637	$7H_2O . 2Na_2O_3 . 9FeO . 6B_2O_3 . 14Al_2O_3 . 24SiO_2$ (very variable)
Serpentine	(? Amorphous)	2·47—2·60	3·0		$3MgO . 2SiO_2 . 2H_2O$
Sphene	Monosymmetric	3·3—3·7	5·0—5·5	1·631	$CaO . TiO_2 . SiO_2$
Turquoise	(Amorphous)	2·62—3·0	6·0		$2Al_2O_3 . P_2O_5 . 5H_2O$
Gypsum	Monosymmetric	2·28—2·33	1·5—2·0	1·53	$CaSO_4 + 2H_2O$
Amber	(Amorphous)	1·08	2·0—2·5	1·5	(Hydrocarbon compound)
Jet	(Amorphous)	1·02	2·0—2·3		(Hydrocarbon compound)

The cutting of gems is an industry in itself. Theoretically the angles of the facets should be calculated for each mineral from its refractive index, so as to give the greatest possible brilliance. Practically the form is determined largely by what portion of the gem is free from flaws. There are three principal ways of cutting precious stones; they may be: (1) Rose Cut, (2) Brilliant Cut, (3) cut En Cabochon. (1) A rose cut stone is roughly in the form of a low pyramid, formed of a number of triangular facets. The stone is set with its flat base towards the mount. (2) A brilliant cut stone has the general form of two pyramids, base to base, the one towards the setting being slightly truncated by a plane called the collet. The pyramid which is towards the light is markedly truncated by a plane called the table. (3) A stone cut *en cabochon* has a flat base towards the mount and a convex surface towards the light. Sometimes the surface towards the mount is concave, so that the stone forms a meniscus. A diamond which is to be cut is mounted in pewter, and then pressed on a wheel revolving 2,000 or 3,000 times per minute, with a pressure of 2 to 30 lb. produced by weights. The wheel is of iron, about 9 or 10 in. in diameter, and is dressed with a mixture of diamond dust and oil. The polishing of diamonds was unknown till the middle of the fifteenth century. At Birkenfeld, gems are polished on grindstones of about 4 ft. in diameter, driven by water wheels, and having their under parts dipping into the stream to keep the stones constantly wet. The operator lies at full length on a block hollowed out to fit the chest, and holds the gem on about the level of his eyes.

Position and dust combined usually pave the way for an early death of the workers, from consumption. Many imaginary virtues were attached to the different gems; in fact, the fear of the opal's ill-luck is not unknown now. Reference must be made to some of the works on gems for further details.—W.G.

Precipitate (*Chem.*) A solid formed by the addition to a solution of a gas, a liquid, a solid, or a solution. Thus, if the gas hydrogen chloride is passed into a strong solution of sodium chloride, the latter is precipitated from its solution; if the liquid alcohol be added to a solution of potassium chlorate in water, or ferrous sulphate in water, these salts are precipitated; if the solid zinc be added to a solution of copper sulphate, metallic copper is precipitated; if a solution of potassium iodide be added to a solution of lead acetate, both in water, lead iodide is precipitated. It will be seen, therefore, that to cause a precipitate two courses may be followed: (1) a change in the solvent may be effected so that the dissolved substance becomes less soluble; (2) a change in the dissolved substance may be effected so that a new substance is formed which is insoluble in the solvent used. The former course is a common expedient for purifying substances; the latter course is one commonly adopted in quantitative and qualitative analysis. The completeness of a precipitation depends on the insolubility of a precipitate in the solvent, so that for quantitative analysis the precipitate should be as insoluble as possible; while in qualitative analysis the precipitate need not be so insoluble, although the delicacy of a test depends on the insolubility of a precipitate in many cases For example, when excess of a solution of tartaric acid is added to a solution of potassium nitrate, a white precipitate of cream of tartar is formed, and this is a respectable test for potassium when properly performed; but potassium is never estimated in this way because the precipitate is too soluble in water. *See* QUALITATIVE *and* QUANTITATIVE ANALYSIS.

Precipitated Chalk. *See* CALCIUM COMPOUNDS.

Precipitation (*Meteorol.*) Precipitation occurs when moist air is cooled below the dewpoint, the moisture taking the form of rain, snow, hail, dew or frost depending on the conditions under which condensation takes places and is maintained.

Precipitato, Precipitoso (*Music*). Hurriedly.

Preciso, Precisione, con (*Music*). With precision.

Prehistoric Architecture. Megalithic structures are the most important examples of prehistoric architecture which have lasted till the present time. They consist of circles and avenues of large stones, either in the form of MENHIRS (single upright stones) or DOLMENS (pairs of vertical stones supporting lintels). The circles are known as CROMLECHS.

Prehnite (*Min.*) An acid calcium aluminium orthosilicate, $H_2Ca_2Al_2Si_3O_{12}$. Pseudo-Rhombic. Usually in green or yellowish mammillated masses, with a radiating crystalline structure, rarely showing distinct terminations to the crystals. It is found in some eruptive and metamorphic rocks. Boyleston, Old Kilpatrick, etc., near Glasgow; Edinburgh; Dauphiné; China, etc.

Preliminary (*Typog.*) This term is used to denote matter that precedes the main text of a work, *e.g.* title, preface, contents, list of illustrations, etc.

Preller's Leather. *See* CROWN LEATHER.

Preparing, Prepared (*Lace Manufac.*) Relates to yarn that is rolled or calendered.

Pre-Raphaelite Brotherhood (*P.R.B.*) An association of artists formed about 1848, and consisting at first of W. Holman Hunt, D. G. Rossetti, and J. E. Millais. Subsequently there were associated with them T. Woolner, F. G. Stephens, and J. Collinson. The objects of the association were a closer study of nature, and to protest against certain academic dogmas. *The Germ*, the organ of the association, of which only four numbers were published, was issued in 1850. Its principle was "to enforce and encourage an entire adherence to the simplicity of nature." This principle was to apply to poetry as well as painting. Ruskin described the methods of the association as an attempt "to paint things as they probably did look and happen, not as, by rules of art developed under Raphael, they might be supposed to gracefully, deliciously, or sublimely have happened." The association continued until 1854.

Press. The literature of newspapers; collectively the representatives of newspapers who attend meetings for the purpose of taking reports.

—— (*Bind.*) The name given to several appliances used in bookbinding, *e.g.* arming, blocking, lying, sewing, standing press, etc. (*q.v.*)

—— (*Eng., etc.*) A general name for a machine, worked either by hand or power, adapted for many purposes, *e.g.* crushing various substances; forcing a body to assume a more compact form; expressing oil, wine, etc.; impressing a design on metal or other substance; printing. *See* TYPOGRAPHY.

Pressed Bricks (*Build.*) Bricks that have been pressed in a mould before baking. This renders them very dense.

Pressed Glass. *See* GLASS MANUFACTURE.

Presse Pate (*Paper Manufac.*) An apparatus for converting wet pulp into sheets in papermaking.

Presser, Flatware (*Pot.*) A potter who makes such flat ware as plates, saucers, dishes, etc.

Pressing (*Lace Manufac.*) A process that it is necessary brass bobbins should undergo after being filled with material, to restore them to a workable thickness.

Pressing Block (*Bind.*) One of the wooden blocks used to fill up a STANDING PRESS (*q.v.*) when there are not sufficient books for the purpose.

Pressing Boards (*Print.*) Glazed boards used for pressing printed sheets in order to give them a slight glaze and remove the indentations caused by the type.

Pressman (*Print.*) A term used in England to distinguish the operator of a hand press from the minder of a printing machine.

Press Pin (*Bind.*) A bar of iron used as a lever for operating standing and lying presses.

Press Proof (*Print.*) The final proof marked by the author or publisher "for press."

Press Revise (*Typog.*) The first sheet printed at press or machine. The reader compares it with the author's press proof as a final check against errors and imperfections.

Press Rolls (*Paper Manufac.*) Heavy iron rolls used for pressing the wet paper after leaving the couch rolls.

Pressure. A force exerted on an object (or quantity of material) and acting towards the object. The term pressure is often confined to forces which produce a STRESS (*q.v.*), but do not produce motion. Pressure is usually measured in units of force per unit area.

—— (*Elect. Eng.*) A term often used to denote POTENTIAL DIFFERENCE *or* ELECTROMOTIVE FORCE.

Pressure, Barometric (*Meteorol.*) Atmospheric air exerts a pressure in all directions, and its amount varies according to its density. The air at sea level, weighed down by the air above it, exerts a pressure of nearly 15 lb. per square inch of surface, against which it presses, and this pressure is measured by the barometer.

Pressure Areas (*Meteorol.*) Areas over which relatively "high pressure" or "low pressure" prevails for either short or long intervals of time.

Pressure Forging (*Eng.*) The shaping of wrought iron objects by means of dies actuated by a HYDRAULIC PRESS (*q.v.*)

Pressure Gauge (*Eng.*) An instrument for measuring the pressure of a gas or liquid. The pressure of the fluid actuates the mechanism of the gauge in a great variety of ways; in one of the commonest types of steam gauge the pressure tends to straighten out a bent tube, and the movement produced is communicated to a pointer turning on an axis in the centre of a dial.

Pressure Gradients (*Meteorol.*) *See* GRADIENT.

Pressure of the Atmosphere. This is approximately 15 lb. per square inch. The Normal Pressure used in physics and chemistry as a standard of reference is equal to that exerted by a column of mercury 76 cm. high, and is equal to about 1,013,300 dynes per square centimetre. It has been proposed to take a pressure of 1,000,000 dynes per square cm. (10^6 dynes) as a standard.

Press View. It is customary before an exhibition, etc., is opened to the public to fix a day on which representatives of the Press are admitted to view the exhibits for the purpose of criticism.

Presswork (*Print.*) A term expressing the operations of printing at hand press. It includes laying on the forme, dressing the tympan, making and cutting out the frisket, making ready, inking the forme, laying the sheet on the tympan, running the forme beneath the platen, taking the impression, running out the forme, lifting the tympan, removing the printed sheet, etc.

Prestissimo (*Music*). Very quick.

Presto (*Music*). Quick.

Preticelli Ware. *See* GLASS MANUFACTURE.

Pricker (*Foundry*). A wire used for forming vents in the upper part of a mould to allow the escape of the gases produced when the molten metal is poured in.

—— (*Mining*). A rod used for forming the "touch hole" in blasting with powder.

Pricking Up (*Build.*) The first coat of plaster on a lathed partition or ceiling.

Prima (*Music*). First, chief, as *prima volta, primo* (abbreviated 1°), first time, used before a repeat, when on the repetition other music is to be substituted for that portion marked 1°; *prima donna*, chief operatic female singer.

—— (*Print.*) The piece of copy containing the first words of the next "take" or sheet.

Primary (*Geol.*) A term employed by the older geologists as synonymous with what would now be subdivided as the Deuterozoic (Carboniferous and Devonian), Protozoic (Silurian, Ordovician, and Cambrian), and Eozoic (or Pre-Cambrian) systems.

Primary Alcohol (*Chem.*) *See* ALCOHOL. For examples of primary alcohols *see also* METHYL ALCOHOL *and* PROPYL ALCOHOL.

Primary Amine (*Chem.*) *See* AMINES. For the reactions of a typical primary amine *see under* ETHYLAMINES *and* METHYLAMINE.

Primary Bow (*Meteorol.*) *See* RAINBOWS.

Primary Cells (*Elect.*) *See* CELLS, PRIMARY.

Primary Coil (*Elect.*) That coil of an induction coil, transformer, etc., through which flows the primary current, *i.e.* the original current, whose fluctuations are to be utilised in order to induce another or secondary current in the secondary coil of the apparatus.

Primary Colours (*Light*). *See* COLOURS, PRIMARY.

Primary Hydrocarbon (*Chem.*) One which contains no carbon atom linked to more than two others. *See under* PARAFFINS.

Prime. A number which contains no factors except itself and unity, *e.g.* 3, 5.

—— (*Music*). The generator. *See* HARMONICS.

——, **Priming** (*Paint.*) Covering a canvas or other painting surface with a layer of colour to form a ground. The first coat of paint on woodwork, generally composed of red lead, turpentine, and a little linseed oil. *See* HOUSEPAINTING.

Prime Conductor (*Elect.*) The positive conductor of a frictional or an electrostatic machine.

Prime Vertical (*Astron.*) The vertical circle at right angles to the meridian, *i.e.* which passes through the east and west points of the horizon.

Priming (*Dec.*) The first coat of paint given to a wood, cement, or other surface to form a foundation for the subsequent coats. It is important that it be mixed thin; that is, with sufficient oil to penetrate well into the wood, etc., but not wholly so. The most common priming used is a mixture of white lead and red lead in the proportion of about 1 oz. of the latter to 1 lb. of the former. Yellow ochre mixed with white lead is often employed, but it is important that the ochre be very finely ground, in order that it may penetrate the pores of the wood and form a key for the subsequent coats of paint. An imperfect priming is often the cause of subsequent blistering of the paint. Puttying is executed after the priming coat, to fill up all the cracks and bring all inequalities to a level surface. If the putty is applied to the raw wood or cement, it would extract the oil from the putty and cause it to drop out when dry. It is important when giving the priming coat to see that the brush reaches every part of the surface, into all the cracks, etc. It is also important that the work should be free from moisture when the priming coat is applied. *See* PRIME.

—— (*Eng.*) The technical name for frothing or foaming in a steam boiler. In violent ebullition the bubbles of steam rise so rapidly that particles of water are sprayed up into the steam space and suspended mechanically. The risk of this priming being carried off in the steam pipe is serious, as it disarranges the engine valves and is liable to knock out the cylinder heads. Hence the importance of dry steam, which commercially is held to be such when containing less than $2\frac{1}{2}$ per cent. of moisture. The principal causes of priming, among others, are greasy and dirty water; the injudicious use of caustic and other "softeners" *in* the boiler; insufficient

steam space; too large a steam pipe; deficient water surface area; forced firing; and faulty design. The last named is a more common cause than contracted steam space. As remedial measures the following may be noted: (1) Clean water and passing the condenser feed through an oil separator. (2) Keeping as great a water surface as possible, a vital feature being to ensure the water surface covering at least half the area of each space left for down currents. (3) The use of an anti-priming or dry pipe (*q.v.*) for collecting steam. (4) The area of the steam pipe to be in proportion to the capacity of the boiler. (5) Regulating the water surface so that the steam shall not rise at the rate of more that 2·5 ft. per second; that is to say, the minimum water disengaging surface, in square feet, may be ascertained by dividing the number of cubic feet of steam generated per second by 2·5. (6) Attention to the design of boilers in relation to the foregoing. To remedy existing faulty design, baffle plates may be fixed inside the boiler or the steam pipe area reduced. Though the lowering of the initial pressure may reduce the efficiency of the engine, it is often a lesser evil than that of priming or installing a new boiler.—C. H. N.

Priming of the Tides (*Astron.*) At the time of spring tides the interval between the corresponding tides of successive days is less than the average, and then the tides are said to be "prime."

Priming Valve (*Eng.*) A valve fitted to cylinders in steam engines to afford a vent for water carried in by PRIMING (*q.v.*)

Primo (*Music*). The treble part of a duet, the other part being the *secondo*. *See also* PRIMA.

Primrose Chrome (*Dec.*) The lightest grade of chrome yellow, sometimes called lemon chrome, although this is strictly a slightly deeper colour.

Primuline. *See* DYES AND DYEING.

Principal (*Build.*) A PRINCIPAL RAFTER (*q.v.*)

—— (*Music*). (1) An open metal stop on organs (*see* ORGAN, p. 441). This stop is of 4 ft. pitch on the manuals and of 8 ft. on the pedals, and it is in the Great Organ Principal that the tuner lays the original bearings from middle C to the octave above. (2) Subject, the chief theme of a movement.

Principal Focus (*Light*). Parallel rays of light, after falling upon a mirror or lens, converge to, or appear to diverge from, a point on the axis; this point is termed the PRINCIPAL FOCUS.

Principal Plane of a Crystal (*Phys.*) A plane drawn so as to contain the Optic Axis of a crystal. If the plane be drawn at right angles to a face of the crystal, it is termed the Principal Plane of that face.

Principal Planes of a Lens (*Light*). A pair of planes drawn through the PRINCIPAL POINTS (*q.v.*) at right angles to the axis of the lens.

Principal Points of a Lens (*Light*). These are two points so situated with regard to a lens that a ray travelling towards one of them will emerge, after passing through the lens, as if it came from the other, but parallel to its original direction. These points are also termed OPTICAL CENTRES and EQUIVALENT POINTS.

Principal Rafters (*Build.*) The rafters of a truss, the timbers on which the purlins rest. *See also* ROOFS.

Print. A general term for an impression taken from engraved plates, types, etc. *See also* PHOTOGRAPHY.

—— (*Pattern Making, etc.*) A projection on a pattern. This forms a recess in the mould into which the end of a CORE (*q.v.*) is fitted to hold it in place.

Printer's Devil. A term applied to the junior apprentice in a printing works.

Printer's Ream. Twenty-one and a half quires of 25 sheets, or 516 sheets in all, to allow, after making ready and spoilage, of a product of at least 508 good copies.

Printing Frame (*Photo.*) A wooden frame which holds a negative closely in contact with the printing paper during the process of PRINTING (*q.v.*) When paper or film negatives are used the printing frame is fitted with a glass front.

Printing Ink. *See* INKS.

Printing Telegraph (*Elect. Eng.*) An instrument which prints the message on a strip of paper either in the Morse alphabet (*q.v.*) or, in certain cases, in ordinary type.

Priory. A religious house, *e.g.* a monastery or convent, presided over by a prior or prioress; they rank respectively next to an abbot and abbess.

Prising (*Eng., etc.*) Moving an object by means of a lever or crowbar. Forcing open by leverage, *e.g.* a door or box.

Prism. A solid whose sides are parallelograms, and whose ends are equal polygons, lying in parallel planes. Prisms are described by the form of the base (or cross section), *e.g.* as triangular, square based, etc.

—— (*Phys.*) The term is applied, especially in physics, to a portion of refracting material in the form of a prism, usually of triangular cross section. BOTTLE PRISMS are glass vessels of triangular cross section with accurately plane sides, for containing a refracting liquid. *See also* ERECTING PRISM, SPECTROSCOPE, *etc.*

Prismatic Camera (*Astron.*) A camera used for spectroscopic purposes when the prism or grating is placed in front of the object glass.

Prismatic Compass. A form of compass used in surveying. It is provided with a sight and reflecting prism so arranged that while an object is viewed through the sight, the bearing of the line to it may be simultaneously read by means of the reflection of the graduated scale in the prism.

Private View. The privilege of viewing pictures, etc., granted to exhibitors, their friends, and others, prior to the admission of the public.

Process. *See under* PHOTO ENGRAVING.

—— (*Biol.*) A portion of some cell, organ, or other structure which forms a projection; *e.g.* many bones have processes, which serve as points of attachment for muscles, ligaments, etc.

—— (*Mining*). A Cornish term for the percentage of metal in a given ore.

Prochous (*Archæol.*) A small pitcher-shaped vase somewhat resembling the Œnochœ. Used by the Greeks for pouring water over the hands before meals.

Producer (*Eng.*) A form of cupola furnace used for making PRODUCER GAS (*q.v.*)

Producer Gas (*Eng.*) A mixture consisting essentially of hydrogen, oxides of carbon (CO and CO_2),

nitrogen, etc., formed by blowing air through red-hot coke, coarse coal, or other carbonaceous fuel. There are many modifications of the process. The general result is a gaseous fuel of little or no illuminating power but considerable calorific value, suitable for use in furnaces of nearly all kinds, and also for driving gas engines.

Products of Combustion. The results of the combustion of ordinary fuel are carbon dioxide, CO_2; water vapour, H_2O; carbon monoxide, CO, etc. If the gases from a furnace are rich in CO, they can be utilised further as fuel.

Profile. The outline or contour of anything, especially the human face as seen sideways; also the outline of a building, projection of a moulding, piece of country, etc., shown by section.

—— (*Pot.*) A mould made of fired pottery and used by the plate or saucer maker to form the foot of the piece.

Progression. A series or succession of quantities each one bearing a definite relation to those which precede and follow it, *e.g.* a common difference in ARITHMETICAL PROGRESSION, or a common ratio in GEOMETRICAL PROGRESSION. Thus 1, 5, 9, 13 are numbers in arithmetical progression, and 1, 5, 25, 125 are in geometrical progression.

Projection. A method of depicting an object on a plane surface by the use of straight lines called projectors. It can be orthographic projection or perspective projection. In the latter case the visual rays are the projectors. If a straight line be drawn from a point at right angles to a plane, its intersection with the plane is the ORTHOGRAPHIC PROJECTION of the point; also, if a straight line be drawn from a point to the eye of the spectator, it cuts the plane of the picture at a point which is the PERSPECTIVE PROJECTION of the original point.

Projection Lens. A lens or combination of lenses used for the formation of an image upon a screen. *See* LANTERN OBJECTIVE.

Prominences (*Astron.*) Incandescent clouds, varying in size and form, round the limb of the sun. They are projections from the chromosphere, and attain enormous dimensions. They can be seen or photographed any time when the sun shines.

Pronaos (*Architect.*) *See* CELL.

Prong Chuck. A forked chuck used to give rotation to a piece of wood mounted between the centres of a lathe.

Prony Brake (*Eng.*) *See* DYNAMOMETERS, MECHANICAL.

Proof (*Engrav., etc.*) An impression taken from an engraved plate, lithographic stone, etc., to prove the condition and progress of the engraving, etc., during its execution; one of a limited number of impressions taken before the title, etc., is added to the plate or stone, and known as a PROOF IMPRESSION, FIRST PROOF, or PROOF BEFORE LETTERS. *See* FIRST PROOF.

—— (*Typog.*) Preliminary impression of type matter either in slip, page, or sheet form.

——, **Artist's** (*Engrav., etc.*) A proof of an engraving, etc., signed by the artist. The signature of the artist is a guarantee of the satisfactory condition of the plate.

——, **Lettered** (*Engrav., etc.*) A proof of an engraving, etc., that bears in the margin the title, etc. *See under* PROOF

Proof, Remarque (*Engrav., etc.*) A proof of an engraving, etc., signed by the artist, and bearing in addition a small design, sketch, or other distinguishing mark placed on the margin of the engraving.

Proof Bar (*Met.*) A bar of steel which can be withdrawn from a cementation furnace to show the progress of the operation of CEMENTATION (*q.v.*)

Proof Corrections (*Typog.*) The method of marking errors or emendations in proofs is practically uniform in all printing offices, and the same method is usually adopted by writers. On the next page will be found an example of a corrected proof containing a number of the more common mistakes, and the marks by which the printer is able to rectify them.

Proof Load (*Eng.*) A load greater than that which a structure has to bear when in use, applied to test the strength, deflection, or deformation, etc., of the structure.

Proof Plane (*Elect.*) A small metal disc fixed to an insulated handle, used for transferring small charges of electricity from charged conductors.

Proof Reader (*Typog.*) *See* READER.

Proof Spirit (*Chem.*) A mixture of alcohol (ethyl alcohol) and water defined by Act 58, George III., as "being such as shall at a temperature of 51° F. weigh exactly $\frac{12}{13}$th part of an equal measure of distilled water" (51° F. = 10·5° C.) It contains 49·24 per cent. by weight of alcohol, or 57·09 per cent. by volume of alcohol. The duty on all alcoholic liquors is charged according to the amount of proof spirit they contain, 11*s.* per gallon of proof spirit. Liquors containing more alcohol than proof spirit are called overproof, and those containing less are called underproof. If an alcoholic liquor is described as 10° overproof, it means that 100 parts by volume would give by dilution with water 110 parts by volume of proof spirit. If the liquor is described as 10° underproof, it means that 100 parts by volume of the liquor contain (100-10) = 90 parts by volume of proof spirit.

Proof Stress (*Eng.*) The greatest stress to which a substance can be subjected without exceeding the ELASTIC LIMIT (*q.v.*)

Propane (*Chem.*) $CH_3.CH_2.CH_3$. A paraffin hydrocarbon. *See* PARAFFINS.

Propeller (*Eng.*) *See* SCREW PROPELLER.

Proper (*Her.*) The tincture of a charge is very frequently its own natural colouring; it is then blazoned "proper."

Proper Motion (*Astron.*) After allowing for all the common motions of stars, it is found that they really change their position with reference to each other, each having a particular or proper motion of its own.

Propionic Acid (*Chem.*) $CH_3.CH_2.COOH$. A colourless liquid. Smells like acetic and butyric acids; boils at 140°; soluble in water; insoluble in a solution of calcium chloride. Boiled with bromine it yields α-brompropionic acid, $CH_3.CHBr.COOH$. It occurs in small amount in many different fermentations of sugars, such as glucose and milk sugar. It is best prepared by the hydrolysis of its nitrile—propionitrile or ethyl cyanide—by boiling with a dilute acid or with a solution of caustic potash. The nitrile is obtained by heating ethyl iodide and potassium cyanide at 180° in a sealed tube, and distilling the addition product so formed.

"THE CENSOR OF THE AGE." 9

Thomas Carlyle, a great thinker. essayist, and historian, was born at Ecclefechan, in Dumfriesshire, in the year 1795. He was educated at the burgh school of Annan, and afterwards at the University of Edinburgh. Classics and the hisher mathematics were his favourite studies; and he was more espe cially fond of astronomy. He was a teacher for some years after leaving the university. For a few years after this he was enaged in minor literary work; and translating from the German occupied a large portion of his time. In 1826 he married Jane Welsh, a woman of abilities inferior only to his own. His first original work was *Sartor Resartus* ("The Tailor Repatched"), which appeared in 1834, and excited a great deal of attention. Perhaps his most remarkable book is The French Revolution. In 1865 he completed the hardest piece of work he had ever undertaken, his *History of Frederick II.*

One of the crowning external honours of CARLYLE'S life was his appointment as *Lord Rector* of the University of Edinburgh in 1866; but at the very time that he was delivering his famous and remarkable Installation Address, his wife lay dying in London.

This stroke brought terrible sorrow on the old man; he never ceased to mourn for his loss, and to recall the virtues and the beauties of character in his dead wife. "The light of his life," he said, "was quite gone out"; and he wrote very little after her death.

Carlyle was an author by profession, a teacher of and prophet to his countrymen by hismission, and a student of history by the deep interest he took in the life of man. He was always more or less severe in his judgments—he has been called The Censor of the Age"—because of the high ideal which he set up for his own conduct and the conduct of others. He shows in his historic writings a splendour of imagery and a power of dramatic grouping second only to Shakespeare. In command of words he is second to no other modern English writer.

B

"THE CENSOR OF THE AGE." 9

THOMAS CARLYLE, a great thinker, essayist, and historian, was born at Ecclefechan, in Dumfriesshire, in the year 1795. He was educated at the burgh school of Annan, and afterwards at the University of Edinburgh. Classics and the higher mathematics were his favourite studies; and he was more especially fond of astronomy. He was a teacher for some years after leaving the University. For a few years after this he was engaged in minor literary work; and translating from the German occupied a large portion of his time. In 1826 he married Jane Welsh, a woman of abilities only inferior to his own. His first original work was *Sartor Resartus* ("The Tailor Repatched"), which appeared in 1834, and excited a great deal of attention. Perhaps his most remarkable book is *The French Revolution.* In 1865 he completed the hardest piece of work he had ever undertaken, his *History of Frederick II.*

One of the crowning external honours of Carlyle's life was his appointment as Lord Rector of the University of Edinburgh in 1866; but at the very time that he was delivering his famous and remarkable Installation Address, his wife lay dying in London. This stroke brought terrible sorrow on the old man he never ceased to mourn for his loss, and to recall the virtues and the beauties of character in his dead wife. "The light of his life," he said, "was quite gone out"; and he wrote very little after her death.

Carlyle was an author by profession, a teacher of and prophet to his countrymen by his mission, and a student of history by the deep interest he took in the life of man. He was always more or less severe in his judgments—he has been called "The Censor of the Age"—because of the high ideal which he set up for his own conduct and the conduct of others. He shows in his historic writings a splendour of imagery and a power of dramatic grouping second only to Shakespeare's. In command of words he is second to no modern English writer

B

EXPLANATION OF THE CORRECTIONS.

1. The line should not be "indented" (*see* 12) in this case, the reason being that the first words of the paragraph are altered to capitals and small capitals.
2. When it is required to alter words from lower-case letters to capitals, three lines are placed beneath them; to small capitals, two lines: and to italics, one line.
3. Substitute a comma for a full-point.
4. The letter "g" is upside down.
5. The letter "h" is to be taken out, or "deleted."
6. A "hyphen" is omitted. In all cases of omission a caret (∧) is marked in the place, and the character written in the margin, except in the case of long sentences being left out, when the words "Out—see copy" are written instead.
7. Substitute capital U for lower-case letter. *See* 2.
8. The letter "g" is to be inserted. *See* 6.
9. *w.f.* (wrong fount) indicates that the letter marked belongs to another fount of type.
10. *trs.* signifies the transposition of letters or words.
11. Underlined for italics. *See* 2.
12. *N.P.*, or *new par.*, commence a new paragraph by indenting the line one em.
13. As in the case of roman being marked to italic, the words required to be in roman are underlined once, and *rom.* (roman) is written in the margin.
14. *See* 13.
15. The matter has some foreign substance between the lines, causing them to appear crooked. Lines are written above and below the words not in alignment.
16. The paragraph should not have been broken here, but should "run on," these words being placed in the margin.
17. The letter is face downwards.
18. Substitute a full-point for the semicolon, and commence a new sentence.
19. A space to be put in between the two words, to separate them.
20. The letters in the word are too far apart, and should be closed up.
21. A space is standing up.
22. A battered letter.
23. When inverted commas or superior letters are to be inserted, they are usually written above the sign shown in the margin.
24. The reader has mistakenly crossed out the word. To indicate that it must be retained, dots are placed beneath it, and the Latin word *stet* (let it stand) is written in the margin.
25. The spaces between the words are not equal
26. Apostrophe to be inserted. *See* 23.
27. Delete the word "other"

Proportion. Proportion is the equality of ratios. Thus four quantities, *a*, *b*, *c*, *d*, are in proportion if

$$\frac{a}{b} = \frac{c}{d}$$

Proportional Arms (*Elect.*) *See* WHEATSTONE'S BRIDGE.

Proportional Compasses. A pair of compasses consisting of two bars each pointed at both ends, and provided with a common fulcrum which can be placed at any required position along the bars. With the fulcrum fixed in any position there is a definite ratio between the extent to which the ends open out, and this ratio is kept constant while the instrument is being used for copying any drawing on a different scale from the original.

Propulsion System of Ventilation. By this method of ventilation fresh air is driven mechanically, by means of bellows, pumps, or fans, into the building.

Propyl (*Chem.*) A name given to the residue remaining when one hydrogen atom is removed from propane. As this can be done in two ways, there is: (1) The normal propyl group obtained by removing one atom of hydrogen from either of the terminal carbon atoms of propane. (2) The isopropyl group obtained by removing one atom of hydrogen from the middle carbon atom of propane.

$CH_3 . CH_2 . CH_2$, normal propyl.
$CH_3 . CH . CH_3$, isopropyl.
$\quad\quad\;\;|$

Exs.: Conine (*q.v.*) is *a*-propylpiperidine. Cymene (*q.v.*) is paramethylisopropylbenzene.

Propylæa (*Architect.*) A monumental gateway in front of a building or group of buildings. The propylæa of the Acropolis at Athens is a fine example.

Propyl Alcohols (*Chem.*) (1) Normal propyl alcohol, $CH_3CH_2CH_2OH$, is a colourless liquid. Smells like ordinary alcohol; boils at 97°; soluble in water; insoluble in strong calcium chloride solution. Chemically its behaviour is like that of ethyl alcohol. It is one of the constituents of fusil oil, and can be prepared from some kinds of fusil oil by fractional distillation. It also occurs in small quantities in various fermentations of cane and grape sugar. Artificially it can be made by the reduction of the anhydride of propionic acid by sodium amalgam. (2) Isopropyl alcohol, $CH_3 . CHOH . CH_3$, is a colourless liquid. Alcoholic smell; boils at 83°; soluble in water, and forms various hydrates with it. The hydrate $2C_3H_8O . H_2O$ has a constant boiling point at 80°. On oxidation it yields acetone. It may be obtained by reduction of acetone with sodium amalgam. *See* KETONES. It is also prepared by boiling isopropyl iodide with water and a weak alkali, such as lead hydroxide. The isopropyl iodide may be obtained from glycerine by distilling it with amorphous phosphorus and an excess of fuming hydriodic acid. Normal propyl alcohol can be converted into isopropyl alcohol by heating it with concentrated sulphuric acid to form propylene, uniting the latter to concentrated sulphuric acid and distilling the product with water:

$$\begin{array}{cccc} CH_3 & CH_3 & CH_3 & CH_3 \\ | & | & | & | \\ CH_2 \;\; - & CH & CH . HSO & CHOH \\ | & \| & | & | \\ CH_2OH & CH_2 & CH_3 & CH_3 \end{array}$$

Proscenium. The part of a modern theatre stage that lies between the curtain or drop scene and the orchestra; the curtain and the frame from which it hangs. In an ancient theatre the proscenium comprised the whole of what is now known as the stage, but it was merely a narrow raised platform, with a scene at the back. The actors stood at the front.

Prostylar *or* **Prostyle** (*Architect.*) A temple having a columnar porch at one end only. *See* ANTA *and* AMPHIPROSTYLE.

Protamines (*Chem.*) The simplest proteids. They are found united with nuclein in the heads of the spermatozoa of a number of fish, *e.g.* salmon, sturgeon, herring, mackerel, and others, and they are named after the fish from which they are obtained. The protamines from the fishes mentioned are called respectively salmine, sturine, clupeine, scombrine (Latin names). The free protamines are difficult to prepare in pure condition, and are usually obtained as sulphates. The formulæ of the four protamines mentioned are approximately:

Sturine	$C_{24}H_{71}N_{17}O_9$
Scombrine	$C_{32}H_{72}N_{16}O_8$
Clupeine	$C_{30}H_{62}N_{14}O_9$
Salmine	$C_{30}H_{57}N_{17}O_6$.

They are white solids; not coagulated by heat; their solutions are precipitated by ammonium sulphate and by common salt; they are fairly strong bases; their sulphates are soluble in water, insoluble in alcohol, and are precipitated by picric acid. They give the biuret reaction, and are precipitated by the alkaloid reagents (*q.v.*) They are hydrolysed by trypsin, but not by pepsin. Dilute acids also hydrolyse them. The first products of hydrolysis are called PROTONES, and are the peptones of the protamines. Further hydrolysis resolves them into the Hexone bases, arginine, histidine, lysine, of which arginine is much the more frequent and abundant (84 per cent. in the case of salmine):

Arginine = guanidine-*a*-amino-valerianic acid,

$$\begin{array}{l} \quad\quad NH_2 \\ \quad\quad\;\, | \\ HN = C . NH . CH_2 . CH_2 . CH_2 . CHNH_2 . COOH \end{array}$$

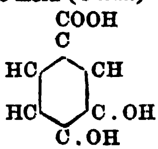
Histidine = $C_6H_9N_3O_2$, of unknown constitution.
Lysine = *a*, *ε*-diaminocaproic acid = $CHNH_2CH_2 . CH_2 . CH_2 . CHNH_2 . COOH$.

Proteids (*Chem.*) A general term used to include a large number of substances which form the most important constituents of the bodies of plants and animals. These substances are composed of carbon, hydrogen, nitrogen, oxygen, sulphur, and phosphorus, the first four being always present, the last two not always. The constitution is unknown in every case, and only in the case of the simplest members is even the formula approximately known. They are called by one general name because of the mode of their occurrence, their optical activity (all lævo-rotatory), the general similarity of their decomposition products, their colloidal character (although many of them can be crystallised, they are nevertheless colloids), their colour reactions. The proteids may be divided into the following classes: (1) Simple proteids, such as the albumins (*q.v.*), globulins (*q.v.*), casein (*q.v.*) (2) Compound proteids, such as hæmoglobin (*q.v.*); the nucleo-proteids, which are compounds of simple proteids with a substance (or substances) called nuclein, which forms the chief constituent of cell nuclei and yields nucleic acids (*q.v.*) on decomposition. (3) Albuminoids, such as gelatine (*q.v.*) and elastin. (4) Protamines (*q.v.*) Among the products of hydrolysis of proteids,

whether the hydrolysis is effected by acids, alkalis, or enzymes, may be mentioned glycocoll (*q.v.*), alanine (*q.v.*), leucine (*q.v.*), aspartic acid (*q.v.*), glutaminic acid (*q.v.*), tyrosine (*q.v.*), arginine, histidine, lysine (*see under* PROTAMINES for these three), and other products. *See* HÆMOGLOBIN.

Proterozoic System (*Geol.*)

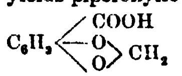
Protocatechuic Acid (*Chem.*)



Pale yellow needles, containing one molecule water of crystallisation; the anhydrous acid melts at 199°, and loses carbon dioxide, forming pyrocatechol (*q.v.*) Soluble in water, alcohol, ether. Ferric chloride gives a green colour to its solution, turning blue, then red on addition of alkali; reduces ammoniacal silver. On treating it with halogen alkyls and alkylens and caustic potash, it yields ethers; *e.g.* methyl iodide yields vanillic and veratric acids,

$$\underset{3}{C_6H_3}(\underset{4}{OCH_3}).\underset{1}{OH}.COOH \text{ and } C_6H_3(OCH_3)_2COOH.$$

Methylene iodide yields piperonylic acid,



See PIPERONAL. It is formed on fusing certain resins with caustic potash, such as asafœtida, catechin, kino; and in the same way from piperic acid. *See* PIPERINE. It is also formed by heating pyrocatechol (*q.v.*) with ammonium carbonate at 140°.

Protoplasm (*Biol.*) The essential living substance of animal and plant organisms. It is of a viscous consistency and semitransparent. It is an unstable complex compound of carbon, hydrogen, oxygen, nitrogen, sulphur, and perhaps phosphorus.

Protozoic (*Geol.*) One of the four great divisions into which the whole of the Sedimentary Rocks have been divided. The oldest during which life first came into being upon the Earth is the Eozoic. Next to this, when the earliest forms of life yet known prevailed, is the one under notice; following that comes the Deuterozoic or second type; and finally appear the forms of life which are more or less closely related to those of the present day, which is called the Neozoic. It begins with the Dyas or Lower New Red. This classification is based upon the general facies of the Life of the Past at different periods in the Earth's history.

Protractor. A divided scale used for marking angles on paper. It may be straight, circular, semicircular, etc.

Protuberances (*Astron.*) *See* PROMINENCES.

Proustite (*Min.*) Silver sulpharsenite, $3Ag_2S.As_2S_3$. Silver = 65·4, sulphur = 19·4, arsenic = 15·2 per cent. Rhombohedral and hemimorphic, occurring in deep red crystals with a submetallic lustre. Chiefly from the Harz Mountain mines. It is also called RUBY SILVER. *See* PYRARGYRITE.

Prunus (*Botany*). An important genus of the *Rosaceæ*. The following are the chief species: *P. cerasus*, the cherry; *P. amygdalus*, the almond; *P. persica*, the peach; *P. domestica*, the plum; *P. armeniaca*, the apricot.

Prussian Blue (*Chem.*) When ferric chloride is added to an excess of a solution of potassium ferrocyanide, a blue precipitate is formed which is completely soluble in much water, giving a blue solution, but insoluble in salt solutions. This substance is called soluble Prussian blue; it is potassium ferric ferrocyanide, $K.Fe.\left\{Fe(CN)_6\right\}$. When potassium ferrocyanide is added to ferric chloride solution, a mixture of soluble and insoluble Prussian blue is formed, and if the precipitate is heated with ferric chloride all the former compound is converted into the latter, and ferric ferrocyanide or insoluble Prussian blue, $Fe_4\left\{Fe(CN)_6\right\}_3$, is obtained. It contains water, which cannot be expelled without decomposition. It is a blue solid with coppery lustre; soluble in ammonium tartrate, giving a violet solution, and in oxalic acid, giving a blue solution. It is decomposed by caustic potash: $Fe_4\left\{Fe(CN)_6\right\}_3 + 12KOH = 3K_4Fe(CN)_6 + 4Fe(OH)_3$. *See also* MERCURY COMPOUNDS. Commercial Prussian blue is a mixture of soluble and insoluble Prussian blue and Turnbull's blue (*q.v.*), obtained by adding ferrous sulphate to potassium ferrocyanide, and oxidising the precipitate with chlorine water or bleaching powder, then treating it with hydrochloric acid to remove ferric hydroxide. It is used as a paint.

—— (*Dec.*) Is one of the most important and one of the cheapest blues used by the house painter. It is made by adding ferrous sulphate to a solution of potassium ferrocyanide. The blue works well both in oil and water. In the lump it possesses, if of good quality, a certain unmistakable copper-like hue. It cannot be used with lime, is not quite permanent when exposed to light, but sufficiently so for all ordinary purposes. Chinese blue is high quality of the same pigment; Brunswick blue, a mixture of Prussian blue and barytes.

Prussian Brown (*Dec.*) A pigment very similar in colour to umber, and made by partially carbonising Prussian blue. It is now very little used.

Prussiate Bath. The solution of yellow prussiate of potash or potassium ferrocyanide used in the BLUE PROCESS for copying.

Prussic Acid (*Chem.*) *See* HYDROCYANIC ACID.

Psaltery (*Archæol.*) A mediæval musical instrument consisting of thirteen strings and a sounding board. The strings were played by plucking them.

Psammite (*Geol.*) A word long in use on the Continent to denote any kinds of rock which consist essentially of sand, whether coarse or fine, and now coming into use in Britain in the adjective form Psammitic to convey the same idea.

Pseudo Acids and Bases (*Chem.*) A pseudo acid is a substance which does not by itself show acid properties, but which on solution in a suitable solvent undergoes electrolytic dissociation at a measurable rate into acid ions. The original substance and its ions have not the same constitution, for during the resolution into ions isomerisation has

occurred. This phenomenon is called ionisation isomerism. An example of a pseudo acid is nitroform. $HC(NO_2)_3$.

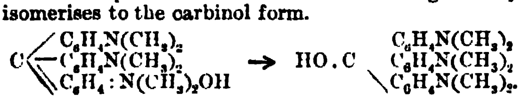
Pseudo Acid. Constitution of Hypothetical Acid which yields the Ions. Salt.

The pseudo acid is a colourless crystalline solid which melts at 15°; in non-ionising solvents (benzene, chloroform, dry ether) it gives colourless solutions, but in presence of water the solution turns yellow, and its conductivity shows it to be a very strong acid. Other examples of pseudo acids are the acid amides

$$R.CO.NH_2 \rightarrow R.C{:}NH \atop \quad OH$$

(Acid from which Salts are derived.)

the nitro- and isonitro-compounds (*see* NITRO COMPOUNDS), the keto-enol compounds (*see* ETHYL ACETOACETATE). Pseudo acids are distinguished in several ways; thus their aqueous solutions neutralise a base gradually, that is as the pseudo acid isomerises; also they have an abnormally great temperature coefficient of conductivity and an abnormally great variation of dissociation with variation of temperature. They do not form salts with dry ammonia in a non-dissociating solvent, but they do so in presence of water. Pseudo bases are substances which in themselves are electrically indifferent, but are isomeric with ammonium hydroxides, and can pass into these, forming ammonium salts. Examples are the ammonium hydroxides of the acridine and quinoline series and a number of colour bases; *e.g.* when caustic soda is added to the hydrochloride of hexamethylpararosaniline, a strongly dissociated alkaline hydroxide is formed which gradually isomerises to the carbinol form.



Pseudo-Dipteral (*Architect.*) A temple having only one range of columns at each side, but the distance of these columns from the side walls is the same as if there had been two ranges. *See* DIPTERAL.

Pseudoisatin (*Chem.*) *See* ISATIN.

Pseudomorphism (*Min.*) The assumption by one mineral of the form of another. It may occur by the pseudomorphous mineral coating the original, or by the one infiltrating a cast left by the other on its decomposition, or by a gradual replacement of one mineral by another, or, lastly, by some chemical change occurring in the original mineral without change of form.

Pseudo-Peripteral (*Architect.*) A temple somewhat resembling a peripteral temple, but attached columns are used on one side or more instead of a series of detached columns. *See* PERIPTERAL.

Psilomelane (*Min.*) Hydrous manganese manganate, H_4MnO_5: not crystallised; occurs in mammillated masses of black colour. It contains 70 to 80 per cent. of the oxides of manganese, and nearly always some barium. It is often associated with other manganese ores, and may occur in any of their localities.

Psychrometer (*Meteorol.*) An instrument for determining the relative humidity of the atmosphere by the temperature of evaporation. It consists of two similar thermometers, the bulb of one being covered by thin muslin connected to a wick dipping into water.

Pt (*Chem.*) The symbol for PLATINUM (*q.v.*)

Ptera (*Architect.*) The ranges of columns surrounding a Grecian temple. *See* PERISTYLIUM.

Pteroma (*Architect.*) Spaces between the side walls or pteromata of a temple and the range of columns surrounding it.

Pteromata (*Architect.*) The side walls of a Grecian temple. *See* PTEROMA *and* PTERA.

Ptomaines (*Chem.*) A name given by Selmi to substances obtained from corpses which have basic properties show the general reactions of the plant alkaloids, but are not identical with any of these, and some of which are poisonous. A knowledge of their properties and the methods of isolating them is very important in some cases of poisoning, as cases have arisen in which persons have been suspected of administering an alkaloid when death has really been caused by ptomaine poisoning. Ptomaines arise in several distinct ways: (1) In flesh, by the process of putrefaction; (2) as products of the action of bacteria, the bacteria being contained in the flesh, but not producing ptomaines until the flesh is eaten; (3) in certain shell fish, such as the mussel, when it lives in water contaminated by sewage or in stagnant water. Chemically, ptomaines belong to very different classes of compounds. Some are derivatives of ammonium hydroxide (*see* CHOLINE, MUSCARINE, *and* NEURINE); others are diamines (*see* CADAVERINE *and* PUTRESCINE); others are pyridine derivatives, and many are of unknown constitution, as, for example, the substance called mytilotoxine, $C_6H_{15}NO_2$, which is believed to be the mussel poison; and the substance called tyrotoxicon, which does not give the alkaloid reactions, but resembles diazobenzene in its poisonous action, and which is obtained from cheese. The mode of origin of some ptomaines is intelligible. Choline, neurine, muscarine, betaine, and trimethylamine all arise from LECITHIN (*q.v.*)

Lecithin → Choline (Hydrolysis) ↗ Neurine (by dehydration) → Muscarine (by oxidation) ↘ Betaine (by oxidation) → Trimethylamine.

Arginine is a decomposition product of proteids, and it yields ornithine on hydrolysis, which in turn can yield putrescine.

$$HN{:}C\genfrac{}{}{0pt}{}{NH_2}{NH}.CH_2.CH_2.CH_2.CHNH_2.COOH$$
Arginine.

$$\rightarrow CH_2NH_2.CH_2.CH_2.CHNH_2.COOH$$
Ornithine.

$$\rightarrow CH_2NH_2.CH_2.CH_2.CH_2NH_2.$$
Putrescine.

Lysine, another decomposition product of proteids, might yield cadaverine, just as ornithine yields putrescine:

$$CH_2NH_2.CH_2.CH_2.CH_2.CHNH_2.COOH$$
Lysine.

$$\rightarrow CH_2NH_2.CH_2.CH_2.CH_2.CHNH_2.$$
Cadaverine.

The method of extracting ptomaines is as follows (Brieger's): The substance is slightly acidified with hydrochloric acid, and evaporated to a syrup on a water bath; the syrup is extracted with alcohol,

and a solution of mercuric chloride in alcohol added to the extract. This precipitates the ptomaine as a double salt with mercuric chloride, and this double salt is extracted from the precipitate by hot water. The procedure now depends on the ptomaine present; *e.g.* the double hydrochloric of choline and mercury, if present, will crystallise from the hot solution, while all others remain in solution. The mercury is precipitated from the solution by sulphuretted hydrogen, and the filtrate evaporated to dryness. On extracting the residue with hot alcohol, hydrochlorides of diamines, such as putrescine and cadaverine, remain behind, and so on. The symptoms of ptomaine poisoning are not always the same, but vomiting, purging, prostration, and cramp in the legs are common. A difficulty in the detection of ptomaines arises from the fact that they are only intermediate stages in a long series of decompositions of complex substances, so that they may be present for a few days only, then disappear.

P-Trap (*Build.*) A trap resembling the letter P, having a nearly horizontal outlet.

Ptyalin (*Chem.*) *See* DIASTASE.

Pucella (*Glass Manufac.*) A spring tool: the principal tool of the glass maker. In form somewhat like sugar tongs with the sides flattened at a right angle to the spring and tapering to a point.

Puddled Ball (*Met.*) The mass of puddled iron withdrawn from the furnace.

Puddled Bar (*Met.*) The bars of wrought iron when they leave the rolling mills.

Puddlers' Mine (*Met.*) A mixture of ground hæmatite and water, used in lining puddling furnaces.

Puddling (*Eng.*) (1) Mixing clay with water, either for making a plastic mass or to aid the separation of stones and grit from the clay, as in brickmaking. (2) Filling or lining a space with clay to render it watertight; *e.g.* a cofferdam is made watertight by ramming clay behind the boards. (3) The clay used in the latter operation is itself termed Puddling.

—— (*Met.*) The conversion of brittle pig iron into malleable iron by decarburising the former and removing silicon, phosphorus, sulphur, etc., by atmospheric oxidation. *Cf.* PIG BOILING. *See also* IRON.

Puddling Furnace (*Met.*) A reverberatory furnace in which the operation of puddling is carried on. *See* FURNACES.

Puer (*Leather Manufac.*) A bate of animal dung used for softening hides.

Puering (*Leather Manufac.*) Skins after liming, unhairing, and fleshing are steeped in a fermenting solution of excrement. This process is termed PUERING (*puer*, to stink) when dog excrement is used; bating when the excrement of fowls is employed. *See* BATING.

Pugging (*Build.*) Rough plaster or slag wool laid between the joists of a floor to form a filling and render the floor sound proof.

Pug Mill. A mill used for mixing clay for bricks, materials for making concrete, etc. *See* BRICKS.

Pulley. (1) A general term for a small wheel. (2) A wheel on a shaft driven by or driving a belt.

Pulley Block. A wood or metal frame carrying one or more grooved pulleys over which ropes or chains run.

Pulley Style (*Carp. and Join.*) One of the uprights into which the pulleys are fixed to carry the sashes and weights in a cased frame.

Pulling Up (*Foundry*). The tearing of the sand of a mould whilst the pattern is being withdrawn from the mould.

Pulpit. An elevated enclosed stage in a church from which the preacher delivers his sermon.

Pulp Saver (*Paper Manufac.*) An apparatus for recovering small particles of pulp from surplus backwater.

Pulse (*Botany*). A general term for the seeds of the order *Leguminosæ*, *e.g.* Beans, Peas, and Lentils.

—— (*Music*). *See* BEAT.

Pulvinated (*Architect.*) A pulvinated frieze is one which has a convex face.

Pumice (*Geol.*) Strictly, speaking this term should be restricted in its scientific application to the volcanic froth which has been formed at the surface of a liquid lava of acid composition, and which has been blown into the air from the crater from time to time while small explosions of steam were rising through the fluid mass. These frothy ejections, full of vapour cavities, but consisting essentially of volcanic glass or obsidian, have in many cases fallen back outside the crater, and have thus contributed to the growth of the volcanic cone. The best pumice is obtained from the Lipari Island, mostly from the Campo Bianco.

Pumicestone (*Dec.*) Pumice has important use in painting, by assisting in the production of level surfaces and by reducing inequalities. It is used with water, and is first rubbed flat on one side, so as to prevent scratching. Carriage painters more frequently use specially made pumice composition blocks. Powdered pumice is employed with a felt rubber and water to rub down certain varnished surfaces, and in order to get a perfectly smooth ground for subsequent coats of varnish

Pumping Engine. An engine specially fitted for driving pumps for any purpose. Very large engines are used in mines for drawing off the water from the workings, and it was in this connection that steam engines were first used. Many large pumping engines are beam engines, following the type of the early steam engines.

Pumps. The principle of the common LIFT PUMP is shown in fig. 1. A piston or BUCKET A fits smoothly in the BARREL B, and is raised and lowered by the rod C. A pipe E dips into the water to be raised. As the piston is raised a partial vacuum is produced in the barrel, and water rises in the pipe E, passing through the FOOT VALVE D as soon as the pressure of the air in the barrel has been sufficiently diminished. When the piston descends, D closes, and the valve F, termed the BUCKET VALVE, opens, and allows the water to pass through the opening into the space above the bucket. When the piston rises again, F closes, and the water is lifted until it flows out of the spout G. The actual height to which water can be

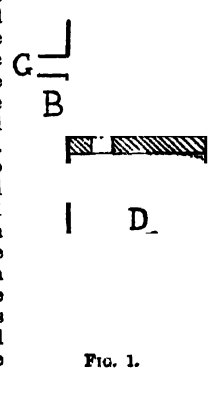


FIG. 1.

drawn is about 25 ft., measured from the level of the water in the reservoir below the pump to the position of the bucket when at the highest point of its stroke. When water has to be raised through a greater height than this, some form of FORCE PUMP (fig. 2) is used. The piston or PLUNGER of this pump is solid. The action during the ascent of the piston is similar to that of the lift pump; but as the piston descends, the water is forced through a valve A and up the pipe B. The height to which the water can be forced now depends only upon the force which is applied to the piston or plunger during the downstroke.

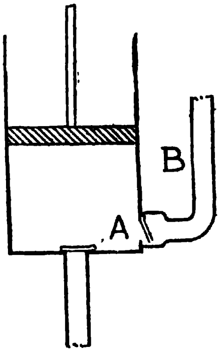

FIG.

The discharge from a force pump may be made continuous by the use of an air vessel (fig. 3). Water enters the chamber A through B, and escapes through the pipe C, whose diameter is so adjusted that during the downstroke of the pump the water enters through B more rapidly than it can escape through C. As a consequence, the air in the space D is compressed, and the water in A is under considerable pressure at the end of the downstroke. This pressure causes the water to flow through C after the downstroke ceases, and, if the vessel be of sufficient size, this flow will become continuous. Many modern types of pump driven by power are constructed on the principle of the force pump. Some of these are double acting. An inlet and an outlet are provided at each end of the barrel, so that the flow of water through the pump is analogous to the movement of the steam in the cylinder of a steam engine. A totally different principle is used in the CENTRIFUGAL PUMP. The moving portion consists of a number of curved blades mounted on an axle, by which they are set in rapid rotation. This part, or FAN, is contained in a circular casing, provided with inlets at the centre and a wide outlet at the circumference, running in a tangential direction. The water fills the casing, and is set in rotation by the blades; centrifugal force drives it outward, and it flows through the discharge pipe in a steady stream, while fresh water is continually drawn into the casing through the inlet pipe. A centrifugal pump is not suited to very high lifts, and it only works with its maximum efficiency at the one lift for which it was designed.

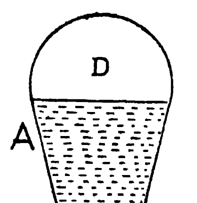

FIG. 3.

Puna Winds (*Meteorol.*) Very dry winds which pass over the barren tableland, called the Puna, to the east of Arequipa in Peru. These winds are parched to a degree that has perhaps no parallel in any other country.

Punch. A steel tool used for forming holes in thin metal, etc., by driving the point through with blows from a hammer; also for a great variety of purposes apart from this use, *e.g.* used by carpenters and joiners for driving the heads of nails below the surface of woodwork.

Punched Holes (*Eng.*) Commonly used in riveted work, such as boilers, girders, etc. The holes are usually made by a punching machine, but the plate is apt to be weakened by punching, and drilled holes are preferable.

Punching (*Masonry*). Dressing masonry with a tool known as a punch.

Punching Machine (*Eng.*) A machine for driving a large punch by power; used in all boiler shops, etc.

Punta (*Music*). The point, as *colla punta dell' arco*, with the point of the bow.

Purbeck Beds (*Geol.*) Rocks of fluviomarine origin, in Britain, which occupy a position intermediate between the Wealden Strata and the Portland Rocks, and, according to many British authors, forms, with them, the uppermost Jurassic Rocks. At and near Purbeck these strata have yielded an exceedingly interesting suite of mammalian fossils which otherwise would have remained almost entirely unknown.

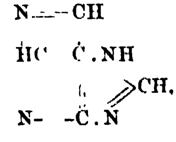
Purchase. A term signifying leverage.

Purification of Sewage (*Civil Eng.*) Sewage is purified by processes which may be classified in a manner similar to those adopted for the purification of water. The presence of the grosser part of the sewage may be very largely dealt with by settling tanks, but bacteriological methods are gaining ground. *See* SANITATION, SEPTIC TANK SYSTEM, *and* SEWAGE; *also* FILTERS, FILTRATION.

Purification of Water (*Civil Eng.*) This is effected by three means: (1) Mechanical, *e.g.* by LEAPING WEIRS (*q.v.*), SETTLING TANKS (*q.v.*), or by simple filtration. (2) Chemical means, *e.g.* by Clark's Process for softening water. (3) Bacteriological means. Bacteria and other organisms have a great effect in the purification of water, the conditions of which are very complex and not completely understood.

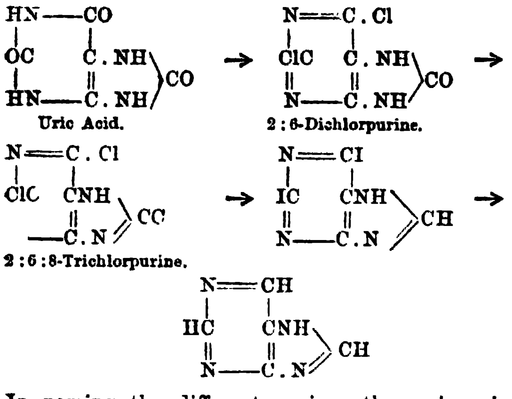
Purifiers (*Gas Manufac.*) *See* GAS MANUFACTURE.

Purines (*Chem.*) Are derivatives of PURINE

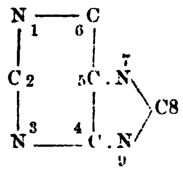


a white solid, crystallising in minute needles from toluene; melts at 216° to 217°, and volatilises on further heating, with partial decomposition; very soluble in water; neutral reaction, but forms salts with acids, behaving as a monacid base. It is stable towards oxidising agents, and thus does not yield the murexide test (*q.v.*) It is obtained from uric acid by converting it into the potassium salt, acting on this with phosphorus oxychloride at 160° to 170°, and treating the dichlorpurine so obtained with the same reagent at 150° to 155°, obtaining 2:6:8-trichlorpurine. The trichlorpurine heated with hydriodic acid and phosphonium iodide at 0° yields 2:6-diiodopurine, which, on boiling with zinc dust and water in a stream of carbon dioxide, gives purine as an insoluble zinc compound. The latter is decomposed by boiling with water and passing in sulphuretted

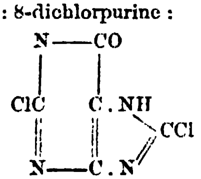
hydrogen: on filtering and concentrating in a vacuum the purine crystallises out.



In naming the different purines the purine ring is numbered as shown in the diagram:



Examples: uric acid is 2 : 6 : 8-trioxypurine. The 2 : 6 : 8-trichlorpurine mentioned above crystallises in plates which contain five molecules water of crystallisation, and is soluble in 70 parts of hot water. It is an important starting point in the synthesis of a number of purine derivatives. When heated with a normal solution of caustic potash it yields 6-oxy-2 : 8-dichlorpurine:



from which guanine, hypoxanthine, and xanthine can be synthesised. *See these.* Hypoxanthine is obtained from 6-oxy-2 : 8-dichlorpurine by reduction with hydriodic acid. The four purine bases adenine, guanine, hypoxanthine, and xanthine are decomposition products of the nucleic acids. Adenine is 6-aminopurine, and it can be obtained from 2 : 6 : 8-trichlorpurine by the action of aqueous ammonia, which yields 6-amino-2 : 8-trichlorpurine, and hydriodic acid reduces this to adenine. The purines caffeine (*q.v.*), guanine, hypoxanthine, theobromine (*q.v.*), and xanthine occur in food stuffs—hence the importance of a careful diet in those suffering from uric acid diseases. Meat, certain vegetables, such as peas, beans, lentils, and asparagus; tea, coffee, cocoa, and beer all contain purines; but milk, butter, cheese, eggs, and white bread contain very little purines. Wines contain no purines.

Purlins (*Build.*) The horizontal beams that support the common rafters. *See* ROOFS.

Purple Brown (*Dec.*) The popular name for purple oxide (*q.v.*) It may be imitated by adding a little ultramarine and lampblack to Indian red.

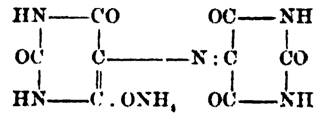
Purple of Cassius (*Chem.*) *See* TIN COMPOUNDS.

Purple Oxide (*Dec.*) A dark reddish purple pigment consisting almost wholly of artificially made ferric oxide. It makes a cheap and serviceable paint, and is usually sold as Purple Brown.

Purpose Made (*Build.*) The term applied to bricks, etc., made to a given pattern.

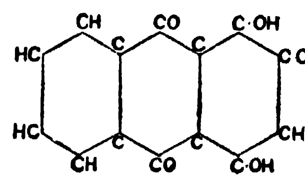
Purpure (*Her.*) Purple, a tincture rarely used in English heraldry. Represented by diagonal lines from left to right. *See under* HERALDRY.

Purpuric Acid (*Chem.*) Not known in the free state. When an acid is added to any of its salts, the purpuric acid decomposes into alloxan and amidobarbituric acid (uramil). Ammonium purpurate, commonly called murexide, is its most important salt:



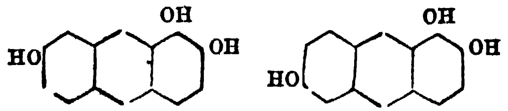
It crystallises in red prisms, which show a fine green lustre by reflected light; sparingly soluble in cold water, much more soluble in hot water; insoluble in alcohol and ether; decomposed by acids into alloxan,  and uramil, 
Caustic potash turns its solution blue. It is obtained by evaporating uric acid with nitric acid, and adding ammonia to the residue (murexide test); by mixing ammonia solutions of alloxan and uramil; by boiling uramil with ammonia and mercuric oxide. Formerly it was much used as a dye, and it is still so used to a small extent.

Purpurin (*Chem.*)



(1 : 2 : 6-trioxyanthraquinone). Crystallises from aqueous alcohol in orange coloured prisms which contain one molecule water of crystallisation. Becomes anhydrous at 100°; sublimes on heating and melts at 253°; soluble in alcohol and ether; slightly soluble in hot water. Dissolves in alkalis, forming a red solution, which is oxidised on exposure to air, turning yellow and yielding phthalic acid. Dissolves in a boiling solution of alum, forming a pink solution with yellow fluorescence. With an alum mordant it dyes a beautiful scarlet red. It is oxidised by nitric acid to phthalic acid; heated with zinc dust it is reduced to anthracene. It occurs with alizarin (*q.v.*) in madder root. It is obtained from alizarin by oxidation with manganese dioxide and sulphuric acid at 150°. Isopurpurin, also called anthrapurpurin, is isomeric with purpurin. Flavo-

purpurin is also isomeric with purpurin. Both isomers are also used as dyes.



Isopurpurin. Flavopurpurin.

Push (*Elect. Eng.*) A contact maker actuated by a stud which is pushed in by the finger; when released it is forced out again by a spring and breaks the circuit.

Putlog (*Build.*) One of the bearers or horizontal members that carry the boards of a scaffold. *Cf.* LEDGERS.

Putrefaction in Meat (*Foods*). This is caused by the presence of putrefactive bacteria, the ferments generated by which give rise to poisonous substances unaffected by cooking. *See* FOODS.

Putrescine (*Chem.*) (Tetramethylenediamine),

$$\begin{array}{l} CH_2 . CH_2 . NH_2 \\ | \\ CH_2 . CH_2 . NH_2 \end{array}$$

A colourless liquid with peculiar smell. Boils at 158° to 160°; soluble in water; difficultly volatile in steam; strong alkali, absorbing carbon dioxide from the air forming the carbonate, and uniting with acids to form salts which are all crystalline. It gives precipitates with all the alkaloid reagents (*q.v.*), and forms a characteristic urea by direct union with phenylisocyanate in dry ether. With benzoyl chloride and caustic soda (Baumann-Schotten reaction, *q.v.*) it yields a dibenzoyl compound—

$$(CH_2)_4 \left< \begin{array}{l} NHCOC_6H_5 \\ NHCOC_6H_5 \end{array} \right.$$

which melts at 175°, and is insoluble in water or ether. Putrescine is not very poisonous. It is one of the ptomaines (*q.v.*), and occurs in putrefying flesh of men and animals, also in pure cultures of the cholera bacillus and occasionally in urine. It can be obtained synthetically by reduction of ethylene cyanide in alcoholic solution by means of sodium:

$$\begin{array}{lllllll} CH_2 & \rightarrow & CH_2Br & \rightarrow & CH_2CN & \rightarrow & CH_2 . CH_2 . NH_2 \\ \| & & | & & | & & | \\ CH_2 & Br & CH_2Br & KCN & CH_2CN & H & CH_2 . CH_2 \;\; NH_2 \end{array}$$

Ethylene. Ethylene bromide.

When pyrrole (*q.v.*) is acted on by hydroxylamine it yields the oxime of succinic aldehyde, which on reduction gives putrescine:

$$\begin{array}{lll} H_2C - CH : NOH & & H_2C - CH_2 . NH_2 \\ | & & \\ H_2C - CH : NOH & H & H_2C - CH_2 . NH_2 \end{array}$$

For a probable explanation of its origin by putrefaction, *see* PTOMAINES.

Putty (*Dec.*) Painters' putty is used for stopping or bringing to a level surface nail holes, abrasions, and other defects in wood or iron work prior to painting or repainting. It is made by mixing whiting with raw linseed oil. The whiting must be free from grit, quite fine, and dry, and the oil should be pure linseed oil only. The admixture is effected in a pug mill or in an ingenious mixer, which is largely employed also by bakers for mixing dough. Sometimes linseed oil foots (*q.v.*) are used, and for putty that is exported to hot countries it is usual to add a little cotton seed oil to retard the drying. Putty is also largely used for glazing windows; but for this purpose an addition of one-tenth part of white lead to the whiting increases the durability of the putty, and is almost a necessity when glazing in exposed positions—such, for instance, as the roof of a greenhouse or conservatory.

Putty (*Build.*) Plasterers' putty is thin mortar, *i.e.* mortar with a considerable quantity of water added.

Putty Joint (*Plumb.*) A joint made with red and white lead covered with a piece of rag and bound with string.

Putty Powder (*Glass Manufac.*) Stannic Oxide. *See* TIN COMPOUNDS.

Puy (*Geol.*) A provincial term in use in the Auvergne district (and elsewhere) for the isolated volcanic cones which form so conspicuous a feature in the scenery of that part. The use of the term has now been extended so as to apply to the local accumulations arising from any small volcano, in contradistinction to the more widely extended volcanic products which come from great volcanic aggregates like those of Hawaii, Iceland, and others.

Pycnostyle (*Architect.*) The name given to the spacing of the columns in a Grecian temple when the space between the columns is equal to one and a half times the lower diameter of the shaft. *See* SYSTYLE, EUSTYLE, ARÆOSTYLE, DIASTYLE, *and* INTERCOLUMNIATION.

Pylon (*Architect.*) A structure of the shape of an oblong truncated pyramid placed on each side of the entrance to an Egyptian temple.

Pynkometer (*Phys.*) A vessel which is filled up to a definite mark with any given liquid in order to compare the specific gravity (*q.v.*) of one liquid with that of another. The commonest form is a small flask provided with a stopper pierced by a small hole; the flask is nearly filled with the liquid, and the stopper is inserted, when the superfluous liquid rises through the hole and can be removed by wiping the flask. The whole is now weighed, and the operation repeated with a different liquid. Deducting the weight of the empty flask, we obtain the weights of two equal volumes of the different liquids. This form is usually termed a SPECIFIC GRAVITY FLASK.

Pyramid. A solid whose sides are triangles having a common vertex, and whose bases form the sides of a polygon, termed the BASE of the pyramid.

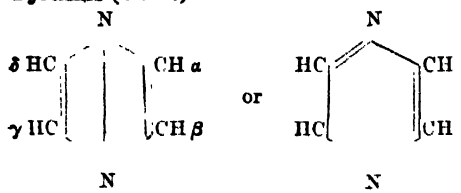
—— (*Archæol., etc.*) A structure, generally of stone, with a square base and triangular sides, the latter meeting in an apex. The most notable examples are the pyramids of Egypt, especially those at Gizeh. The Great Pyramid over the tomb of Cheops stood on a base 756 feet square, and rose to a height of 481 feet.

—— (*Min.*) A closed crystalline form, whose faces cut three axes; the faces are in two symmetrical groups, one group on either side of a plane or base whose outline is determined by the crystalline system to which the pyramid belongs.

Pyrargyrite (*Min.*) One of the Red Silver Ores or Ruby Silvers. *See* PROUSTITE. Sulphantimonite of silver, $3Ag_2S . Sb_2S_3$. Silver = 59·8, sulphur = 17·7, antimony = 22·5 per cent. Rhombohedral and hemi-

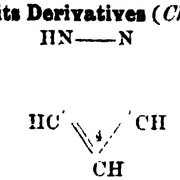
morphic. It is rich dark red by transmitted light; by reflected light almost black, with a submetallic lustre. Chiefly from the Harz Mountain mines.

Pyrazine (*Chem.*)

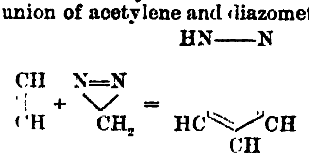


A solid crystallising in colourless prisms. Melts at 52°; boils at 118°; sublimes at the ordinary temperature; smells like heliotrope; its vapour burns with a reddish flame. It is a weak base; it combines with many salts to form double compounds, *e.g.* $C_4H_4N_2HgCl_2$. It is formed by distilling piperazine, which is hexahydropyrazine, with zinc dust; also by heating pyrazine carboxylic acids which lose carbon dioxide and yield pyrazine; also by heating amino-acetaldehyde with a solution of mercuric chloride. Methyl pyrazines are probably among the products obtained when dextrose is heated with a solution of ammonia under pressure. The *a*, *γ*-dimethylpyrazine is formed when glycerine is distilled with ammonium salts (mixture of chloride and phosphate), and it occurs in some fusil oils. The methyl pyrazines are oxidised to carboxylic acids by potassium permanganate.

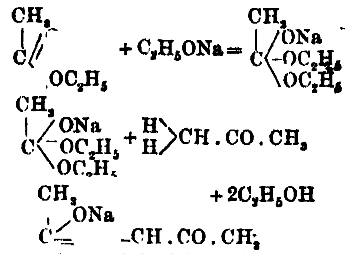
Pyrazole and its Derivatives (*Chem.*) PYRAZOLE,



A colourless solid crystallising in long needles; melts at 70°; boils at 185°; soluble in water, alcohol, ether. In its chemical behaviour it resembles both pyridine and benzene, the former in combining with metallic chlorides such as mercuric chloride, and, in the property of its hydrochloride, combining with platinic chloride, and also in the fact that the 1-alkyl pyrazoles smell like pyridine, and both pyrazole and pyridine are weak bases. It resembles benzene in the stability of the ring towards oxidising and reducing agents; with strong sulphuric acid it forms a sulphonic acid; with strong nitric acid it forms a nitro-compound (NO_2 at 4°), which can be reduced to an amido-compound, and the latter undergoes the diazo-reaction, etc. Pyrazole behaves as a secondary base. With ammoniacal silver nitrate it gives a white precipitate of silver pyrazole, the silver displacing the hydrogen at the nitrogen atom; with acid chlorides the same hydrogen is replaced by the acid radical. Pyrazole can be obtained: (1) By direct union of acetylene and diazomethane:

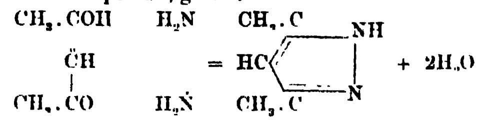


(2) By the following, which is a particular case of a general reaction which is patented by Knorr from the acetyl acetone stage onwards. Ethyl acetate and acetone undergo condensation with sodium or sodium ethoxide:



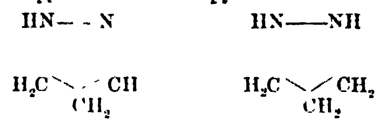
Sodium Salt of Acetyl Acetone.

The acetyl acetone, on treating with hydrazine sulphate and caustic potash, gives:



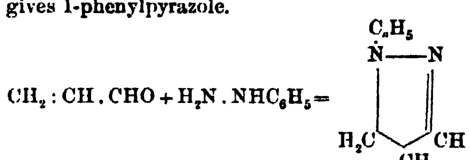
3 : 5 - dimethylpyrazole.

The 3 : 5-dimethylpyrazole, on oxidation with potassium permanganate, gives the corresponding dicarboxylic acid, which goes smoothly into pyrazole on heating. Pyrazole derivatives are named by mentioning the substituting group and its position in the numbered ring. Also the following names must be noticed: Dihydropyrazole is called pyrazoline, and tetrahydropyrazole is called pyrazolidine.



Pyrazoline B.P. 144°. Pyrazolidine (not obtained).

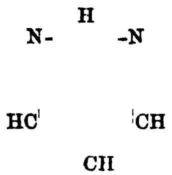
When two hydrogens attached to the same carbon atom are replaced by an oxygen atom, thus giving a ketone group, the termination "-ine" is changed to "-one." Examples below. PYRAZOLE HOMOLOGUES are obtained in various ways: (1) By action of an alkyl iodide on the silver compound of pyrazole. (2) By the second reaction for the preparation of pyrazole given above, which is a general reaction; *e.g.* instead of using hydrazine, substituted hydrazines can be employed. (3) By transposition of the methyl iodide compound of other pyrazoles. The following homologues are important: 1-phenylpyrazole; a liquid boiling at 246° is formed from epichlorhydrin and phenylhydrazine, or from acrolein and phenylhydrazine, when a phenylpyrazoline is first formed, which easily loses hydrogen and gives 1-phenylpyrazole.



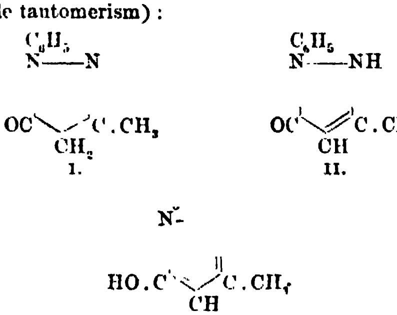
1-phenylpyrazoline.

1-phenylpyrazole combines with methyl iodide, and the compound so formed when heated yields 1-phenyl-4-methylpyrazole, the methyl group leaving the nitrogen and wandering to position 4. Two isomeric phenylmethylpyrazoles, *viz.* 1-phenyl-3-methyl and 1-phenyl-5-methyl, are obtained by the condensation of oxymethylene acetone ($CH_3COCH : CHOH$, by condensation of ethyl formate and acetone by sodium

ethoxide) and phenyl hydrazine. On oxidation, both isomers yield *the same* compound, namely 3-methylpyrazole. The same methylpyrazole is obtained by condensation of oxymethylene acetone and hydrazine. *Hence it appears that the positions* 3 *and* 5 *in the pyrazole ring are equivalent.* It is concluded that the imide hydrogen is labile, and belongs equally to the two nitrogen atoms; to express this the formula for pyrazole is often written

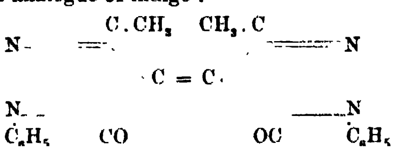


1-PHENYL-3-METHYL-5-PYRAZOLONE. This is the compound formed by the action of phenylhydrazine on ethylacetoacetate (*q.v.*) and treatment of the product with caustic potash; it melts at 127°, and is prepared on a large scale for the manufacture of antipyrine. Although it is known in one form only, it reacts as if it could assume three different formulæ (double tautomerism):

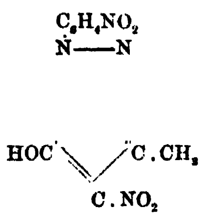


I. II. III.

Examples: According to I. (methylene form), when it is oxidised by ferric chloride to pyrazole blue, the pyrazole analogue of indigo:

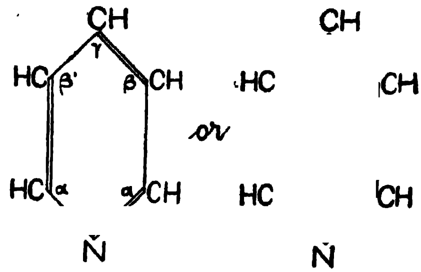


According to II. (imine form), in antipyrine (*q.v.*), which is 1-phenyl-2:3-dimethyl-5-pyrazolone. According to III. (phenol form), in picrolonic acid, which is 1-paranitrophenyl-3-methyl-4-nitro-5-pyrazolone:

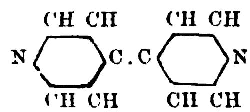


This acid is the picric acid of the pyrazole series, and is obtained by nitration of 1-phenyl-3-methylpyrazoline; like picric acid, it forms numerous sparingly soluble salts with bases, and lately has been used as a reagent in the isolation and characterisation of

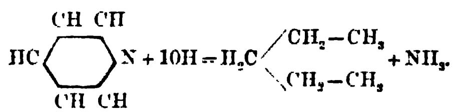
Pyridine (*Ch m.*)



A colourless liquid; characteristic unpleasant smell; poisonous; boils at 115°; soluble in water, alcohol, etc.; it is a base forming salts with acids, *e.g.* $C_5H_5N . HCl$; this hydrochloride unites directly with platinic chloride, forming $(C_5H_5NHCl)_2PtCl_4$, which on prolonged boiling with water forms the yellow insoluble compound $\left\{Pt(C_5H_5N)_2Cl_2\right\}Cl_2$; it also unites with mercuric chloride to form double salts, such as $C_5H_5NHCl2HgCl_2$. It is a tertiary base, uniting directly with alkyl iodides. *See* below. With metallic sodium at 80° it forms γ, γ-dipyridyl

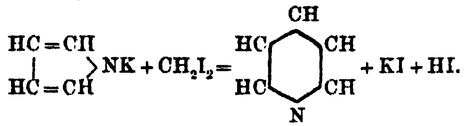


and other products. With sodium and alcohol it yields piperidine (*q.v.*) Heated with hydriodic acid at 300°, it yields normal pentane and ammonia:

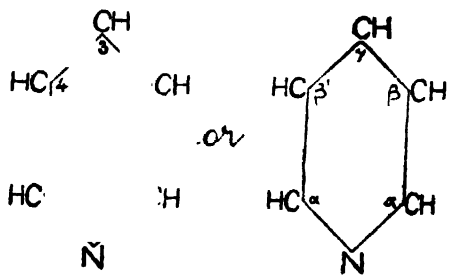


The pyridine ring is very stable, and pyridine is not attacked by boiling concentrated nitric acid nor by chromic acid; ordinary concentrated sulphuric acid does not attack it, but fuming sulphuric acid forms β-pyridine sulphonic acid. Pyridine does not readily give halogen substitution products with the halogens directly: these are obtained by indirect means, *e.g.* by heating pyridine with phosphorus pentachloride, which yields $\alpha\alpha'$ dichlorpyridine. Pyridine and its homologues occur in coal tar, in bone oil, and in shale oil. Pyridine has also been found in tobacco smoke and in the smoke laden air of towns. It is obtained from coal tar. To extract it the tar is distilled, and that fraction which comes over between 60° and 150° is shaken with strong sulphuric acid; the sulphuric acid extract is then heated to boiling to expel neutral substances, and, after cooling, caustic soda is added. The basic oil which separates is purified by fractional distillation; in this way an impure pyridine is obtained which may be purified by adding mercuric chloride to its solution in hydrochloric acid, crystallising the double salt, and distilling it with caustic soda. Pyridine is largely used as a solvent; during the last few years it has been very largely used, especially abroad, for mixing with alcohol to render it undrinkable. Interesting laboratory methods of obtaining pyridine are: (1) By

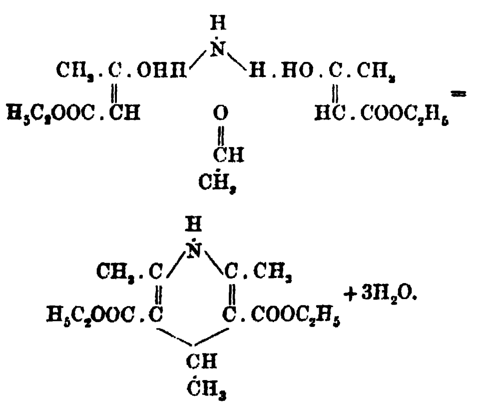
heating pyridine carboxylic acids with soda lime, just as benzene is obtained from benzene carboxylic acids. (2) By heating the potassium compound of pyrrole with methylene iodide:



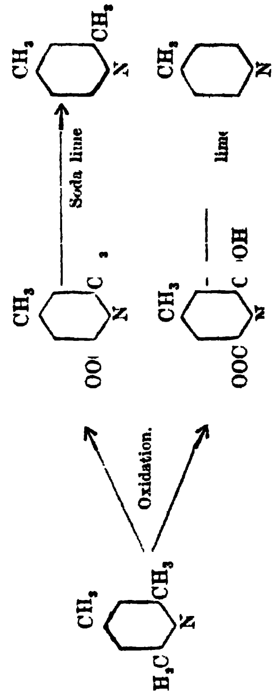
Similarly, β-chlorpyridine is obtained if chloroform be used in place of methylene iodide. (3) By heating piperidine (*q.v.*) with concentrated sulphuric acid. Pyridine derivatives are named by numbering the carbon atoms of the ring or by denoting the carbon atoms by a letter:



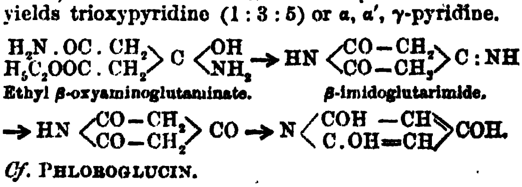
As the carbon atoms 1 and 5 are similarly situated, in lettering the ring these positions are indicated by the same letter, and when both positions are occupied one letter is distinguished by a dash; similar remarks apply to the positions 2 and 4. It is useful to remember that the positions α and γ are similar to the ortho- and para-positions in benzene, while the β position is similar to the meta-position in benzene. HOMOLOGUES OF PYRIDINE: The monomethyl pyridines are called PICOLINES, and are distinguished as α-picoline, β-picoline, γ-picoline; the dimethyl pyridines are called LUTIDINES; the trimethyl pyridines are called COLLIDINES. A very important pyridine synthesis, and one by means of which a number of these homologues may be obtained, consists in heating together ethyl acetoacetate (52 grs.) and aldehyde-ammonia (15 grs.):



The ethyl dihydrocollidinedicarboxylate so formed readily loses two atoms of hydrogen on reduction by nitrous acid, and on treating the product with caustic potash it is hydrolysed, yielding collidine dicarboxylic acid. This acid, on heating with soda lime, yields collidine (αα′γ-trimethylpyridine).



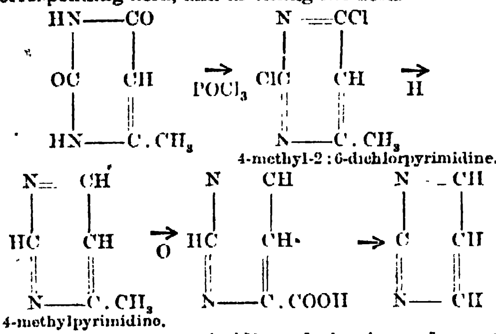
The synthesis can be varied by using other aldehyde ammonias, and in place of one molecule of ethyl acetoacetate, other ketonic acids or 1 : 3-diketones. Pyridine homologues are also obtained by heating alkyl iodide compounds of pyridine, when the alkyl group leaves the nitrogen and wanders into the nucleus, the γ-position being occupied first, then the α-position. The β-position is never occupied in this kind of transposition (similarity to benzene ring). All homologues of pyridine on oxidation yield pyridine carboxylic acids. PYRIDINE CARBOXYLIC ACIDS: Some of these are important as products obtained by breaking down several alkaloids; *e.g.* NICOTINIC ACID from nicotine is 2-pyridine carboxylic acid. CINCHOMERONIC ACID from cinchonine is 2 : 3-pyridine carboxylic acid. Quinolinic acid, obtained by oxidation of quinoline, is the 1 : 2-pyridinecarboxylic acid. HYDROXYPYRIDINES: The α- and γ-hydroxypyridines have the property of behaving like ketones, as well as like hydroxy-compounds. On this account they are also called PYRIDINES. Examples: If the ethyl ester of acetone dicarboxylic acid (from citric acid by the action of strong sulphuric acid) be heated with ammonia, it forms the ethyl ester of β-oxyaminoglutaminic acid, which, when treated with an alkali, forms β-iminoglutarimide, and this with concentrated hydrochloric acid yields trioxypyridine (1 : 3 : 5) or α, α′, γ-pyridine.



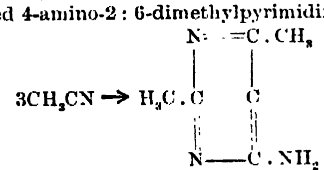
Cf. PHLOROGLUCIN.

Pyrimidines (*Chem.*)

PYRIMIDINE.  A white solid; melts at 20° to 22°; boils at 124°; has penetrating and narcotic smell; soluble in water, giving a neutral solution; yields crystalline, sparingly soluble double salts with mercuric and gold chlorides. It is obtained from methyl uracil (*see* ETHYL ACETOACETATE) by heating it with phosphorus oxychloride, reducing the methyldichlorpyrimidine so obtained with zinc dust and water, oxidising the resulting methylpyrimidine with dilute potassium permanganate solution to the corresponding acid, and distilling the acid.



There are three pyrimidine derivatives of great importance in the chemistry of the proteids. They are: URACIL or 2 : 6-dioxypyrimidine; THYMIN or 5-methyl-2 : 6-dioxypyrimidine; CYTOSIN or 6-amino-2-oxypyrimidine. These are all crystalline solids obtained by decomposition of nucleic acids. Uracil was first obtained from yeast, thymin from the thymus gland, and cytosin from the same source. Pyrimidines are also obtained where nitriles are caused to polymerise under the influence of metallic sodium or sodium ethoxide. Thus from acetonitrile is obtained 4-amino-2 : 6-dimethylpyrimidine —



Pyrites (*Min.*) *See* IRON PYRITES.

Pyrites Burners (*Chem.*) Furnaces used for burning iron pyrites (FeS_2) in air with the object of producing sulphur dioxide for use in the manufacture of sulphuric acid. *See* SULPHUR COMPOUNDS.

Pyrocatechin (*Chem.*) *See* CATECHOL.

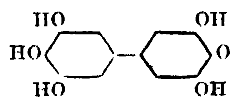
—— (*Photo.*) This substance, sometimes called CATECHOL, is the same in composition as Hydroquinone, having the formulæ $C_6H_4(OH)_2$. It is very soluble in water, and used as a developer produces negatives of excellent quality. It has the advantage of being uninfluenced by temperature and of keeping well in solution.

Pyroclastic Rocks (*Geol.*) *See* CLASTIC ROCKS.

Pyroelectricity. Certain minerals, and some other crystalline substances, become electrified on heating or cooling, and are said to be PYROELECTRIC. Among the former are Tourmaline, Calamine, and Boracite (*q.v.*); and among the latter Cane Sugar and Sulphate of Quinine. The phenomena may be illustrated by the case of Tourmaline; while this is being heated, one end becomes positively electrified, the other end negatively; on cooling, the charges are reversed. The results are not only shown by a complete crystal, but also by a broken piece.

Pyrogallic Acid (*Chem.*) A common name for PYROGALLOL (*q.v.*)

Pyrogallol (*Chem.*) 
(PYROGALLIC ACID *or* 1 : 2 : 3-TRIHYDROXYBENZENE). A white solid crystallising in white shining leaves or needles; melts at 132°; soluble in water; less soluble in alcohol and ether; its solution in water gives a blue colour with ferrous sulphate, containing some ferric salt, and a red colour with ferric chloride. Its alkaline solution reduces gold, silver, and mercury solutions to the metal, the pyrogallol being oxidised to acetic and oxalic acids; it also reduces copper sulphate to cuprous oxide. The alkaline solution rapidly absorbs oxygen from the air, turning brown, then black, and being oxidised as above. On these actions of pyrogallol is based its application as a developer in photography and as a solvent for oxygen in gas analysis. If baryta water is used as the alkali, the oxidation does not proceed so far, and it is possible to isolate 3 : 4 : 5 : 3′ : 4′ : 5′-hexahydroxydiphenyl —



When pyrogallol is oxidised by an acid solution of potassium permanganate, or, better still, by electrolysis of a solution in sodium sulphate, using a rotating platinum anode, a dye called purpurogallin is formed —constitution not settled, but probably it is a naphthalene derivative. With bromine, pyrogallol yields tribrompyrogallol. Pyrogallol is obtained by heating gallic acid (*q.v.*), alone or with water, at 210°. It is also formed, usually with other products, when numerous phenol derivatives are fused with caustic potash.

—— (*Photo.*) This substance, sometimes called PYROGALLIC ACID, is a benzene derivative, having the formula $C_6H_3(OH)_3$. It is a colourless crystalline substance, very soluble in water, and in conjunction with an alkali was for a long time the principal developer employed for use with gelatine dry plates.

Pyroligneous Acid (*Chem.*) When wood is submitted to dry distillation in iron retorts a distillate is obtained which separates into two parts just as the liquid distillate from coal does. The aqueous distillate from wood is called pyroligneous acid. It is the chief source of acetone, methyl alcohol, and acetic acid. When this acid liquid is neutralised with milk of lime and distilled, a crude calcium acetate remains behind in solution. The solution is evaporated, and the residue carefully heated to expel volatile organic matter; then the residue is distilled with hydrochloric acid, and gives a crude

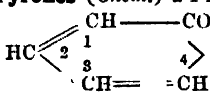
acetic acid of about 50 per cent., which is used for many technical purposes. To obtain glacial acetic acid from the crude acid, it is neutralised with sodium carbonate, evaporated to dryness, fused, and distilled with strong sulphuric acid. The distillate is glacial acetic acid. *See also* METHYL ALCOHOL *and* WOOD SPIRIT.

Pyrolusite (*Min.*) Manganese dioxide, MnO_2. Manganese = 63, oxygen = 37 per cent. Orthorhombic, but usually pseudomorphous after other manganese ores. Colour, iron black. It is of importance in the making of bleaching agents. From Cornwall and many other localities in England; from Thuringia, Moravia, etc.

Pyrometer. Any instrument for measuring temperatures above the range of ordinary thermometers. *See* MEASUREMENT OF TEMPERATURE.

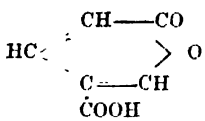
Pyromorphite (*Min.*) A phosphate and chloride of lead, $3Pb_3P_2O_8 . PbCl_2$. It contains 60 to 80 per cent. of lead phosphate and 8 to 10 per cent. of lead chloride. Hexagonal; in short prisms in various shades of green, yellow, and brown. It is a valuable ore when occurring in quantity. From the Cornish mines, Caldbeck Fell mines in Cumberland, Leadhills in Scotland, and many places abroad.

Pyrones (*Chem.*) α-PYRONE—

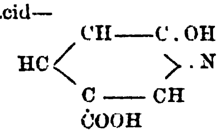


(*also called* COUMALIN).

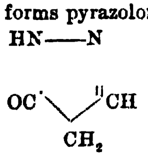
A liquid; melts at 5°; boils with slight decomposition at 206° to 209°, but without decomposition at low pressures; soluble in water; soluble in alkalis forming salts of the acid, $CHO . CH_2 . CH : CH . COOH$; smells like coumarin. It is prepared by distilling the mercurous salt of coumalic acid in a current of steam, and extracting the distillate with ether. *Derivatives:* COUMALIC ACID (α-pyrone-3-carboxylic acid)—



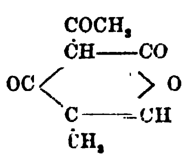
Is obtained by heating malic acid with concentrated sulphuric acid or zinc chloride. Its alkaline salts are yellow. Ammonia converts it (in the cold) to oxynicotinic acid—



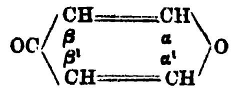
With hydrazine it forms pyrazolone—



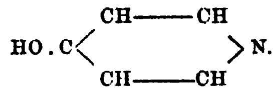
DEHYDRACETIC ACID (1-aceto-3-methyl-αγ-pyrone)—



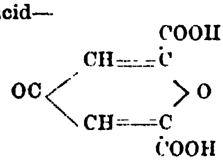
Is obtained when ethyl acetoacetate is heated alone or by the action of pyridine on acetyl chloride. γ-PYRONE—



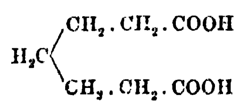
Forms small white crystals, which melt at 32° and boil at 210° to 215°; very soluble in water; reduces Fehling's solution; gives the iodoform reaction. When evaporated with ammonia it gives γ-hydroxypyridine—



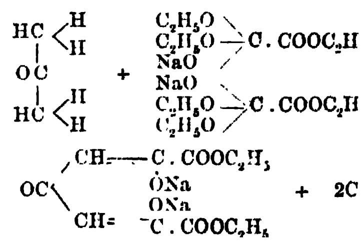
It is obtained by heating chelidonic or comenic acids. Derivatives of γ-pyrone are named by lettering the carbon atoms as shown above, or by numbering all the atoms which form the ring, starting with the oxygen atom as 1. Meconic acid, comenic acid, and pyromeconic acid are γ-pyrone derivatives. *See* MECONIC ACID. Chelidonic acid is γ-pyrone-αα'-dicarboxylic acid—



It crystallises in small needles, which contain one molecule of water, which is lost at 150°; melts at 220°, warmed with alkalis it yields the yellow coloured salts of xanthochelidonic acid (acetone-dioxalic acid); on reduction with hydriodic acid it yields hydrochelidonic acid first, then normal pimelic acid—

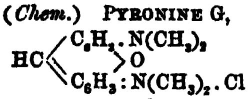


With ammonia it yields γ-oxy-αα'-pyridine dicarboxylic acid. Boiled with milk of lime it gives acetone and calcium oxalate. The acid occurs in celandine along with malic acid. It has been obtained artificially by condensation of ethyl oxalate and acetone by means of sodium ethoxide—



The product on acidifying yields xanthochelidonic ester, which, on heating, loses water and forms the chelidonic ester. *Benzene Derivatives:* Coumarin (*q v.*) is a benzo-α-pyrone. The Flavones (*q.v.*) are derivatives of γ-benzopyrone. The Xanthones (*q.v.*) are dibenzopyrones.

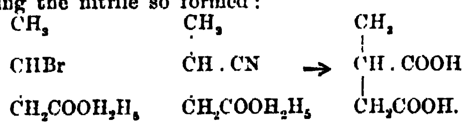
Pyronines (*Chem.*) PYRONINE G,



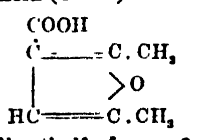
forms shining green crystals soluble in water and alcohol with a red colour showing yellow fluorescence. It is used as a dye for cotton (mordanted with tannic acid), wool, and silk; the shade is bluish red. It is obtained from dimethylmeta-amidophenol (from dimethyl aniline and fuming sulphuric acid, giving the metasulphonic acid, and fusion of the latter with caustic soda) by condensation with formaldehyde, yielding dihydroxytetramethyldiamidodiphenyl methane, which loses water with strong sulphuric acid, forming the leuco compound, and this on oxidation yields the dye. PYRONINE B is the ethyl derivative.

Pyrope (*Min.*) Magnesium aluminium garnet. *See* GARNET. A garnet of deep crimson colour, usually occurring in angular fragments. It is used as a precious stone, and is often cut *en cabochon*. The chief localities are Ceylon and Bohemia.

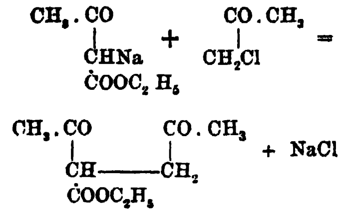
Pyrotartaric Acid (*Chem.*),  (methyl succinic acid). White solid crystallising in groups of small prisms. Melts at 112°; soluble in water, alcohol, and ether. Quickly heated to over 200°, it yields an anhydride; but on keeping it just over 200° it gives butyric acid and carbon dioxide. It contains an asymmetric carbon atom, and can be resolved into its components by strychnine, the dextro form separating first on crystallisation. It is prepared by heating tartaric acid till fumes are evolved, then mixing with its own weight of powdered pumicestone and distilling (nine hours); the distillate is extracted with water, separated from oil, evaporated and crystallised from dilute nitric acid. It can be prepared by heating pyruvic acid; also synthetically from the ethyl ester of β-brombutyric acid by heating with potassium cyanide and hydrolysing the nitrile so formed:



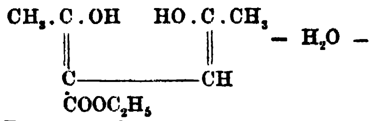
Pyrotritaric Acid (*Chem.*)



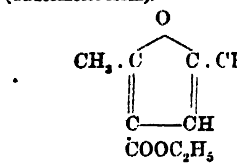
(Uvic acid: $\alpha\alpha'$-dimethylfurfurane-β-carboxylic acid). A white crystalline solid (needles). Melts at 135°; slightly soluble in cold water, more soluble in hot water, very soluble in alcohol and in ether. Heated alone it gives $\alpha\alpha'$-dimethylfurfurane; heated with water at 150 to 160° it forms acetonyl acetone. *See* DIKETONES. It occurs among the products of the dry distillation of tartaric acid; it is also formed when pyruvic acid (*q.v.*) is heated with anhydrous sodium acetate and acetic anhydride at 140°. Synthetically it can be made by the action of monochloracetone (from acetone by the action of chlorine in presence of calcium carbonate) on the sodium compound of ethyl acetoacetate, forming ethyl acetonylacetoacetate, which is then treated with concentrated hydrochloric acid to take away the elements of water:



Ethyl acetonylacetoacetate.



Ethyl acetonylacetoacetate (Tautomeric form).

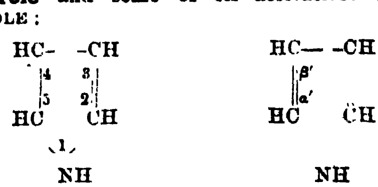


Pyroxene (*Min.*) This term now includes as one species several rock constituents formerly regarded as different. They are normal metasilicates, chiefly of calcium and iron or magnesium, and are monosymmetric. Some varieties contain aluminium, as does one of the best known members of the series, Augite. In colour the Pyroxenes usually range from light to dark green.

Pyroxylin (*Chem.*) A mixture of cellulose nitrates, *viz.* the trinitrate, tetranitrate, and pentanitrate, $C_{12}H_{17}(NO_3)_3O_7$, $C_{12}H_{16}(NO_3)_4O_6$, $C_{12}H_{15}(NO_3)_5O_5$. It is made by immersing pure cellulose (purified cotton wool) in a mixture of sulphuric acid (five volumes sp. gr. 1·84) and nitric acid (four volumes sp. gr. 1·38) for about ten minutes at a temperature of 65° to 70°, then thoroughly washing the product. It is an amorphous white solid, soluble in a mixture of alcohol and ether. This solution is called Collodion (*q.v.*) *See also* CELLULOID.

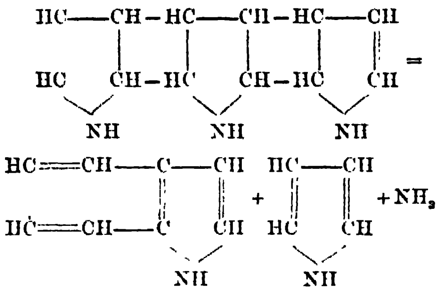
Pyrrhotine (*Min.*) Sulphide of iron, FeS. Iron = 60·5, sulphur = 39·5 per cent. Hexagonal, but usually massive; in brownish masses, with an uneven fracture, metallic lustre and often bronzy tarnish. It is magnetic, and hence is sometimes called Magnetic Pyrites. Sometimes it contains enough nickel to constitute a source of nickel. Widely distributed, but usually in small quantities, and most commonly in connection with metamorphic limestones.

Pyrrole and some of its derivatives (*Chem.*) PYRROLE:

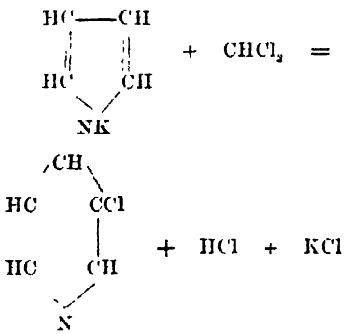


A colourless liquid; boils at 130°; sp. gr. at 12·5°, 0·975. Slightly soluble in water; very soluble in alcohol and in ether; insoluble in dilute alkalis. It

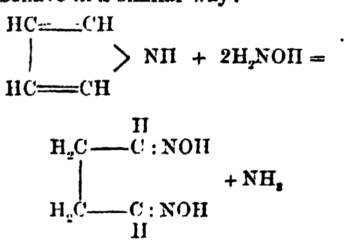
smells like chloroform; turns brown on exposure to air; its vapour turns a pine shaving dipped in hydrochloric acid a red colour—many of its derivatives, *e.g.* those from 1:4-diketones (*q.v.*), hæmopyrrole, indole (*q.v.*), carbazole (*q.v.*), do the same. Pyrrole dissolves in dilute acids, and on warming the solution, or allowing it to stand, an amorphous red substance called pyrrole-red separates; strong acid resinises pyrrole; if the solution in fairly strong hydrochloric acid be neutralised with ammonia, filtered, and the filtrate extracted with ether, a polymer called tripyrrole is obtained—a white crystalline solid which gives indole when heated at 300°:



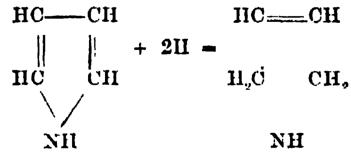
Metallic potassium dissolves in pyrrole with evolution of hydrogen, forming a white crystalline solid, potassium pyrrole, C_4H_4NK; the same substance is obtained by boiling pyrrole with solid caustic potash. Sodium acts far more more slowly. The potassium compound is important, because the potassium is replaced by alkyl groups when warmed with alkyl halogen compounds; also because it yields pyridine when heated with methylene iodide, and β-chlorpyridine when heated with chloroform:



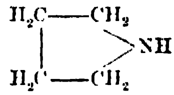
Water decomposes potassium pyrrole into caustic potash and pyrrole. With hydroxylamine pyrrole gives the oxime of succinic aldehyde. Many pyrrole derivates behave in a similar way:



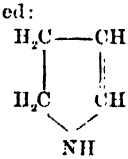
When pyrrole is heated with ammonium carbonate solution at 130° to 140°, it yields pyrrole-a-carboxylic acid. When pyrrole is reduced by zinc dust and hydrochloric acid (the pyrrole is added gradually with shaking, and the strength of the acid is gradually increased), not over 25°, PYRROLINE is formed—a colourless liquid which boils at 90°, fumes in air, and is very hygroscopic:



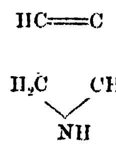
When reduced by hydriodic acid and phosphorus at 240° to 250°, pyrrole yields PYRROLIDINE:



which is a colourless liquid, boiling at 87°, and closely resembling piperidine in its properties; *e.g.* it smells like it, and is a strong base, and it can be obtained by heating the hydrochloride of tetramethylene diamine (putrescine). Pyrrole occurs in coal tar, in bone oil, and in shale oil; it is among the products obtained by the dry distillation of gelatine and of hæmatin. Its chief source is bone oil. The oil is distilled and shaken with dilute acid, to remove strongly basic substances, then fractionated, and the fraction 98° to 150° collected separately; this fraction is boiled with solution of caustic potash under a reflux condenser, to hydrolyse nitriles; it is again fractionated, collecting separately the 115° to 130° fraction; this fraction is heated with solid caustic potash (powder) under reflux condenser; potassium pyrrole is formed: filter, press, dissolve in water, and distil with steam; separate distillate; dry over solid caustic soda; redistil. Pyrrole can be obtained from the ammonium salt of mucic acid (*q.v.*) by distilling it alone, or, better, with addition of glycerine at 200°. It can be obtained from succinimide (*see below*); and by passing acetylene and ammonia through a redhot tube (probable origin of pyrrole in coal tar); by heating its carboxylic acids; and in other ways. For its homologues, *see below*. *Derivatives:* Pyrrole derivatives are named by numbering or lettering the elements which form the ring, as shown above, then indicating the position of the substituting element or group by the proper number or letter, and naming the substituting group. Examples below. The following names are also employed:



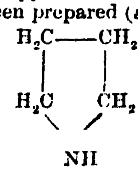
Δ_2-pyrroline.



Δ_3-pyrroline.

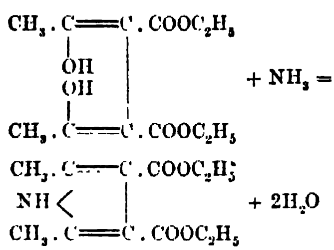
See NOMENCLATURE.

Derivatives of both pyrrolines are known; but only Δ_3-pyrroline has been prepared (*see above*).

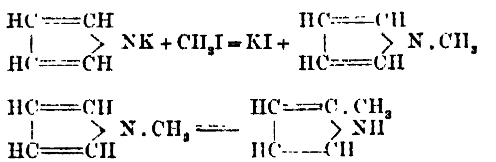


Pyrrolidine.

When in the pyrrolines or in pyrrolidine a CH_2 group becomes a CO group, the new compound is called respectively a pyrrolone or ketopyrroline, a pyrrolidone or ketopyrollidine. Examples below. *Halogen derivatives:* TETRACHLORPYRROLE is an unstable solid; melts with decomposition at 110°. It is obtained by the action of chlorine on an alcoholic solution of pyrrole, or by the action of sodium hypochlorite on pyrrole. Acted on by potassium iodide it yields iodol. TETRIODOPYRROLE (*see* IODOL). *Homologues of Pyrrole:* General reactions for the preparation of these are: (1) Action of ammonia on γ-diketones (*see* DIKETONES), or on their acid derivatives; in the latter case carboxylic acids are formed, and these on heating with quicklime give the hydrocarbons. *Example:* The sodium compound of ethyl acetoacetate when treated with iodine yields diacetyl succinic acid (*see* DIKETONES); this acid is the dicarboxylic acid corresponding to the 1 : 4-diketone acetonyl acetone. With ammonia it yields (working with its ester) 1 : 5-dimethylpyrrole-3 : 4-dicarboxylic acid ethyl ester:

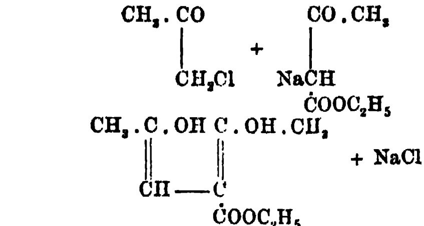


In this synthesis, if a primary amine is used instead of ammonia, the N-alkyl homologues may be obtained. (2) N-alkyl pyrroles may be obtained from potassium pyrrole by the action of alkyl iodides, also by reduction (distillation with zinc dust) of N-alkyl succinimides. These N-alkyl pyrroles on heating are transformed into 1-alkyl pyrroles. Example:

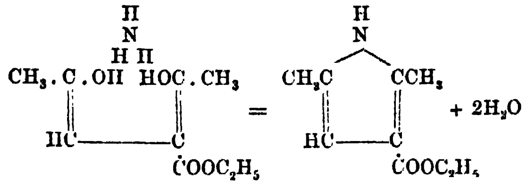


2-methyl pyrrole.

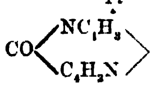
Although not strictly a homologue, β-pyridyl-α-pyrrole may be referred to here. Its preparation is given under NICOTINE (*q.v.*) It consists of white needles, melting at 72°; very soluble in alcohol, ether, and benzene; its solution fluoresces blue. HÆMOPYRROLE (*see* HÆMOGLOBIN) is an oil with characteristic smell; sparingly soluble in water; turns red on exposure to air. The colouring matter produced appears to be identical with UROBILIN. CARBOXYLIC ACIDS: These are obtained by fusing pyrrole homologues with caustic potash; by the action of carbon dioxide upon potassium pyrrole; from pyrrole and its homologues by the action of alcoholic potash and carbon tetrachloride; synthetically in several ways. Example: When monochloracetone acts upon the sodium compound of ethyl acetoacetate and the product is treated with ammonia, the ethyl ester of 1 : 5-dimethylpyrrole-4-carboxylic acid is obtained.



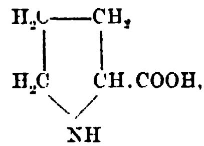
Enol form.



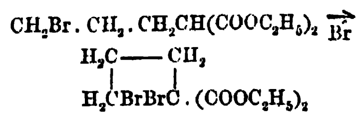
Other γ-ketonic acid esters and other monochlorketones can be used in this synthesis; also the ammonia can be replaced by an amine. A derivative of pyrrole-α-carboxylic acid called *pyrocoll*,



CO, is obtained by the distillation of gelatine. *Pyrroline derivative:* DIHYDRONICOTYRINE (*see* NICOTINE) is a pyrroline derivative. *Pyrrolidine derivatives:* NICOTINE (*q.v.*) is 1-methyl-2-pyridyl pyrrolidine; α-PYRROLIDINE CARBOXYLIC ACID,

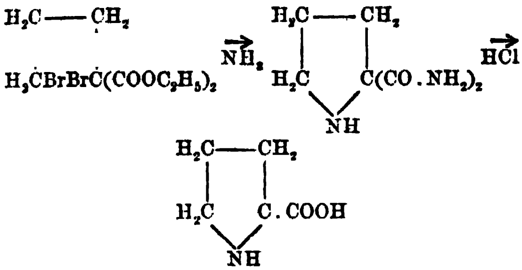


is a decomposition product of proteids. It has been found among the products of proteid hydrolysis by both hydrochloric acid and caustic soda. It was first obtained from casein (3·2 per cent.), and has since been obtained from the most varied proteids. As it contains an asymmetric carbon atom, it can exist in a dextro, lævo, and racemic form. The lævo form has a rotation $[\alpha]_D = -46{\cdot}53°$ in hydrochloric acid solution; α-pyrrolidine carboxylic acid is a white crystalline solid which melts with foaming at 205°. It is soluble in water; has a sweet taste; decolorises alkaline, but not acid permanganate; warmed with silver oxide it gives a mirror. It forms a characteristic copper salt which is sparingly soluble in cold water and easily soluble in warm water. The phenyl cyanate compound is formed in alkaline solution, and melts about 170° with foaming; with difficulty soluble in water. The acid has been synthesised thus: trimethylene bromide (from allyl bromide and hydrogen bromide) and ethyl sodium malonate give ethyl brompropylmalonate, which with bromine forms ethyl α δ-dibrompropylmalonate:

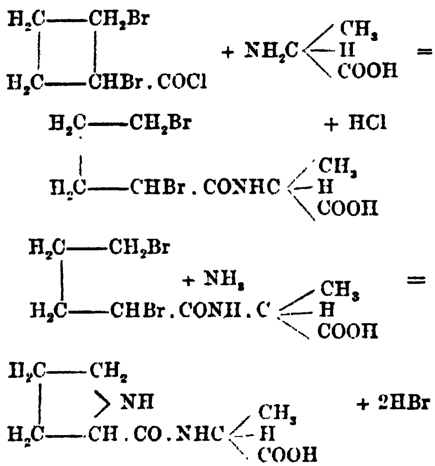


With ammonia the latter yields an amide which is

converted by heating with hydrochloric acid into α-pyrrolidine carboxylic acid :

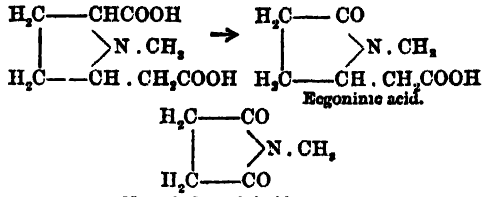


Fischer has proposed the name PROLINE for this acid for shortness. He has combined it with alanine to form a "dipeptide" called PROLYLALANINE by acting on an alkaline solution of alanine with the chloride of α δ-dibromvaleric acid, and treating the product with ammonia:



Prolylalanine is a white crystalline solid, soluble in water, and gives a white precipitate with phosphotungstic acid.

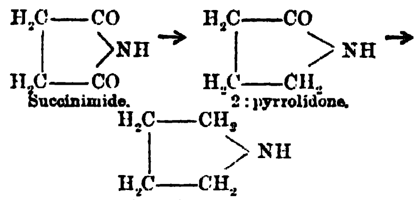
TROPINIC ACID, 
(1-methyl-2-carboxypyrrolidine acetic acid) is a white crystalline solid. As it contains two asymmetric carbon atoms, it should exist in several forms, only three of which are known—namely, an inactive form, a lævo and a dextro form. The inactive form has been resolved by cinchonine. Tropinic acid is obtained by the oxidation of both tropine and ecgonine (*see* ATROPINE *and* COCAINE) by means of chromic acid. The first product of oxidation in each case is tropinone, and this on further oxidation yields tropinic acid. The acid from tropine is inactive, that from ecgonine is dextrorotatory. The lævo acid was obtained by resolution of the inactive acid. The dextro acid melts at 253°, the inactive at 250°, and the lævo at 243°. The inactive acid is very soluble in water, and reduces ammoniacal silver on warming, forming a mirror. On oxidation with concentrated chromic acid tropinic acid yields ecgoninic acid, then N-methyl succinimide :



Ecgoninic acid.

N-methyl succinimide.

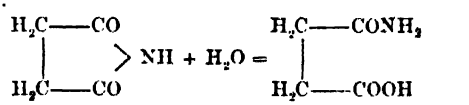
SUCCINIMIDES are 2 : 5-pyrrolidones (or 2 : 5-diketopyrrolidines). Succinimide itself crystallises in colourless plates with one molecule of water of crystallisation ; melts (anhydrous) at 126° ; boils at 228° ; soluble in water, the solution acting as an acid. Distilled with zinc dust it gives pyrrole. When reduced electrolytically, it gives 2-pyrrolidone. Its alcoholic solution, heated with sodium, gives pyrrolidine :



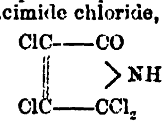
Succinimide. 2 : pyrrolidone.

Pyrrolidine.

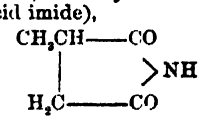
On hydrolysis with an alkali it gives succinamic acid :



With bromine and an alkali it yields β-aminopropionic acid. Phosphorus pentachloride converts it into dichlormaleicimide chloride,



and higher chlorinated pyrroles. Succinimide may be prepared by dissolving succinic acid in 25 per cent. ammonia, evaporating with constant stirring till the temperature rises to 200°, and distilling the product. On re-distillation a pure product is obtained. Homologues of succinimide can be obtained in an analogous way, *e.g.* N-methyl-succinimide by boiling a solution of succinic anhydride with methylamine ; 3-methyl 2 : 5-diketo-pyrrolidine (pyrotartaric acid imide),



by heating its anhydride in a stream of ammonia.

Pyrus (*Botany*). A genus of *Rosaceæ*, including the apple (*P. malus*), pear (*P. communis*), quince (*P. cydonia*), and medlar (*P. germanica*).

Pyruvic Acid (*Chem.*), $CH_3.CO.COOH$ (pyroracemic acid). A colourless liquid. Melts at 3° ; boils at 165° to 170°, with decomposition into carbon dioxide and pyrotartaric acid ; but at a pressure of 12 mm. it distils unchanged at 61°. It smells like

acetic acid; it is soluble in water, alcohol, and ether. On account of the ketone group it shows the reactions of a ketone, *e.g.* it is reduced by zinc and dilute sulphuric acid to lactic acid, $CH_3CHOHCOOH$. Phosphorus pentachloride converts it into α-dichlorpropionic acid; with hydroxylamine it yields an oxime; with sodium hydrogen sulphite it yields an additive compound; with hydrocyanic acid it gives a nitrile; with phenylhydrazine it yields a hydrazone which on being heated with hydrochloric acid gives α-indole carboxylic acid:

$$\begin{array}{l} CH_3 \\ | \\ C:N.NH.C_6H_5 \\ | \\ COOH \end{array} = \begin{array}{l} C \left\langle \begin{array}{l} CH \\ NH \end{array} \right\rangle C_6H_4 + NH_3. \\ | \\ COOH \end{array}$$

Boiled with baryta water it yields pyrotartaric, pyrotritaric, and uvitic acids (*see these*). Pyruvic acid reduces ammoniacal silver nitrate, being oxidised to carbon dioxide and acetic acid. Heated with dilute sulphuric acid at 150°, it gives carbon dioxide and aldehyde. The acid is prepared by distilling previously fused tartaric acid and fractionating the product, or by distilling a mixture of tartaric acid and acid potassium sulphate. Synthetically it is formed by hydrolysing acetyl cyanide, CH_3COCN (from acetyl chloride and silver cyanide), with hydrochloric acid.

Q, *q*. A symbol often used for Quantity, especially a Quantity of Electricity.

Quadrangle (*Architect.*) A square or rectangular court surrounded by buildings.

Quadrant. (1) The part of a circle bounded by two radii at right angles to each other, and by the arc of the circumference lying between them; one-fourth of the area of a circle. (2) An instrument resembling the Sextant (*q.v.*)

Quadrant Electrometer (*Elect.*) *See* ELECTROMETER.

Quadrant Plate (*Eng.*) A plate hinged at the end of the bed of a screw cutting lathe, the axis on which it turns being the end of the leading screw. It carries the change wheels used in screw cutting.

Quadrats (*Typog.*) Metal spaces or blocks of rectangular shape, used for spacing, and especially for filling up short lines. Quadrats stand lower than the face of the adjoining type, and are of various sizes. *See under* TYPE.

Quadrature (*Astron.*) Two heavenly bodies are said to be in quadrature when there is a difference of longitude of 90° between them.

Quadripartite Vaulting (*Architect.*) A form of vaulting in which the vault over each rectangle is divided into four parts. It is formed by the intersection of two barrel vaults, and is also known as a four part vault. *See* GROINED VAULT *and* SEXPARTITE VAULT.

Quadruple Expansion (*Eng.*) The expansion of steam in four successive cylinders of an engine. It is doubtful if this method has any great advantage over TRIPLE EXPANSION (*q.v.*)

Quadruplet (*Cycles*). A form of bicycle propelled by four riders, seated one behind the other.

Quadruplex Telegraphy (*Elect.*) The simultaneous use of a telegraph circuit for four messages, two in each direction.

Quaigh (*Archæol.*) A shallow wooden or metal drinking vessel generally with two handles, at one time common in Scotland.

Quaker Blue (*Dec.*) A dull blue made by adding black to Prussian blue and lightening up by means of a little white.

Quaker Drab (*Dec.*) A greenish grey shade obtained by mixing five parts of white with two parts each of medium chrome yellow and chrome green.

Quaker Greens (*Dec.*) A series of somewhat sombre, greyish greens, having no definite composition or shade. The term is variously applied for trade purposes, generally in contradistinction to the bright greens such as Brunswick, chrome, emerald, etc. The following mixture gives a typical Quaker green, one part each of medium chrome yellow, Venetian red and blue black, and three parts of chrome yellow.

Qualitative Analysis (*Chem.*) The method of proceeding in order to ascertain the nature of an unknown element or compound, or of a mixture of these. (a) *Inorganic:* If the substance is a solution, a part is evaporated. The solid is heated to see if it changes colour (*e.g.* zinc compounds are yellow while hot), if it sublimes (arsenic, mercury, ammonia compounds), if it gives off a gas (many nitrates give off nitrogen peroxide, etc.) The solid is then heated on platinum wire, moistening with hydrochloric acid to form if possible a trace of chloride, the chloride being the most volatile salt of a metal; characteristic colours are imparted to the flame by sodium, potassium, and some other metals. A borax bead is made on the platinum wire, a little of the solid added, and the bead fused in the outer flame; cobalt gives a blue bead, manganese an amethyst coloured bead, and so on. A portion of the solid may be mixed with sodium carbonate and potassium cyanide, as this mixture when heated in the blowpipe flame on a piece of charcoal reduces compounds of the easily reducible metals to the metallic state, *e.g.* tin, lead, bismuth, etc.; then the metal itself can be examined. The action of acid is tried, *e.g.* both dilute and concentrated sulphuric acid, first in the cold, then on warming. Many salts, oxides, and metals give off gases which can be readily recognised, *e.g.* a chloride gives off hydrogen chloride, a carbonate carbon dioxide, and so on. If the original substance is a solid, it must now be dissolved, in water if possible; otherwise suitable acids are tried. If the substance will not dissolve, the chemist knows that it can only contain a few substances, such as silica, alumina, barium sulphate, etc.; he then proceeds to make it into a soluble compound by fusion with sodium carbonate or acid potassium sulphate at his discretion. The examination of the solution is in outline as follows: add hydrochloric acid: silver, lead, mercurous compounds are thrown out as chlorides; any precipitate is filtered off. To the clear liquid sulphuretted hydrogen is added; it precipitates the sulphides of those metals which form sulphides insoluble in dilute hydrochloric acid, *viz.* lead, divalent mercury, bismuth, copper, cadmium, tin, arsenic, antimony. Most of these sulphides have characteristic colours; any precipitate is filtered off. To the clear liquid ammonium chloride and ammonia are added, and more sulphuretted hydrogen; this mixture gives us sulphides of metals which are soluble in dilute acid but not soluble in ammonia, also the hydroxides of aluminium and chromium and certain phosphates; any precipitate is filtered off. To the clear liquid

ammonium carbonate is added, calcium barium and strontium are precipitated as carbonates; any precipitate is filtered off. To a part of the clear liquid sodium phosphate is added; this gives us magnesium as ammonium magnesium phosphate. The rest of the clear liquid is evaporated to dryness and strongly heated, when only sodium and potassium compounds remain. The reagents added above are called *Group Reagents*, and they must be added as long as they produce a precipitate. All the precipitates are then examined separately by suitable methods to ascertain what metals of the group are present. When this has been done the analyst knows what metals are present, and this gives him valuable information as to the acids that may be united with them. The procedure for ascertaining the acids is less systematic: the action of sulphuric acid before mentioned gives valuable information; the solution, properly prepared and treated with barium nitrate and silver nitrate respectively, gives further information, and the analyst's knowledge and discretion decide the remaining operations. (b) *Organic:* The component elements must be ascertained; carbon and hydrogen, by heating with copper oxide, which oxidises any organic compound to carbon dioxide and water; nitrogen, by heating with sodium, which forms sodium cyanide with any organic substance containing nitrogen; if a cyanide is formed it can be detected by converting it into Prussian Blue (*q.v.*); sulphur, phosphorus, and halogens, by heating with nitric acid in a sealed tube, when these elements are converted respectively into sulphuric, phosphoric, hydrochloric, etc., acids, and these can be easily detected. The melting and boiling point should be taken next; if these are constant the substance is probably a pure compound, if not it is a mixture. The substance must now be examined as to its class by making use of reactions suitable to the detection of a hydrocarbon, alcohol, aldehyde, ketone, acid, amine, amide, etc. This being done, the melting point or boiling point will usually settle what particular alcohol, etc., it is. If the substance is a mixture, there is no method applicable to every case, and the analyst must be guided by his knowledge of the source of the substance and by any information he can glean from its chemical behaviour. Thus, if an analyst were given a piece of pitch to analyse he would not return a list of compounds he had extracted from the pitch—that would mean a long research; he would return the constituent elements, and perhaps state what fraction of the pitch was soluble in a particular solvent. In any analysis a substance which has no striking reaction, and is present in small quantity, may easily be missed; thus air had been analysed thousands of times, both qualitatively and quantitatively, before Rayleigh and Ramsay discovered argon in it, although this element forms nearly 1 per cent. of air.

Quandel. The central stake round which wood is arranged in forming a MEILER, *i.e.* the basin shaped stack in which the wood is piled by charcoal burners.

Quantitative Analysis (*Chem.*) The determination of the proportion by weight of any substance or substances contained in the material to be analysed. Before a quantitative analysis can be made a careful qualitative analysis must have been made. Then only can a method for a quantitative analysis be chosen. The analysis may be Gravimetric or Volumetric. In a Gravimetric analysis the substance to be estimated is converted into an insoluble compound of known composition, which can be filtered off, washed till free from excess of the precipitant, dried and weighed. Thus, to estimate the copper in a solution of copper sulphate, a weighed amount of the latter is taken, dissolved in water, a slight excess of caustic soda added to the hot solution so as to form hydrated copper oxide, which is filtered off, washed, dried, and ignited so as to form copper oxide, which can be weighed: the composition of copper oxide being known, it is clear that we should then know the proportion of copper in the original sulphate. For the method of Volumetric analysis *see* VOLUMETRIC ANALYSIS.

Quaquaversal (*Geol.*) An unusual type of inclination of strata in which the rocks dip outwards in all directions from some particular point, so that they form a series of domes or inverted basins over one another. The correlative term CENTROCLINAL DIP is employed in describing the opposite arrangement, in which the strata are inclined inwards towards a central point. This latter arrangement often occurs in volcanic necks.

Quarrel (*Architect.*) (1) A small, square, or diamond shaped piece of glass. (2) A similarly shaped brick, tile, or stone used in paving.

Quarrell (*Arms*). A short, thick, square headed arrow or bolt used with the crossbow. *See also* BOLT.

Quarry. An open pit or excavation from which stone and other materials are dug.

—— (*Architect.*) *See* QUARREL.

Quart. *See* WEIGHTS AND MEASURES.

Quarter. *See* WEIGHTS AND MEASURES.

—— (*Her.*) The canton (*q.v.*) now takes the place of the quarter

Quartered (*Her.*) Divided. *Quarterly:* Divided into four quarters or into more than four sections. A field may be quarterly of six or of eight, etc.

Quartering (*Carp.*) A term generally applied to strips of timber produced by cutting deals (*q.v.*) into four.

Quarterings (*Her.*) Several coats of arms blazoned on one shield either in four equal quarters or in a greater number of sections, according to the number of coats it is necessary to include. The sections are always equal in number, the principal coat being repeated if necessary.

Quarternary (*Geol.*) The geological formations of later date than that of the Pliocene Period.

Quaternary Ammonium Compounds (*Chem.*) Compounds of the type

$$\left.\begin{array}{l} R_1 \\ R_2 \\ R_3 \\ R_4 \end{array}\right\rangle N.X.$$

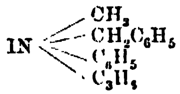
where R_1, R_2, R_3, R_4, are radicals joined to the nitrogen atom by carbon, and X is a hydroxyl group or a halogen. *E.g.* benzylphenylallylmethylammonium iodide,

$$I.N\left\langle\begin{array}{l} CH_2C_6H_5 \\ C_6H_5 \\ C_3H_5 \\ CH_3 \end{array}\right.$$

The quarternary ammonium hydroxides are powerful bases acting like caustic soda or potash; they absorb carbon dioxide from the air and neutralise the strongest acids, forming well crystallised salts. They

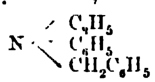
are obtained from amines by the action of alkyl iodides or bromides; this gives the quaternary ammonium iodide or bromide which can be decomposed by moist silver oxide. *E.g.* the above compound can be obtained: (*a*) from methyl aniline by the action of benzyl chloride upon it, yielding methylbenzylaniline,

and then acting on this compound with allyl iodide, yielding

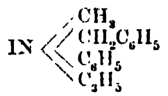


(*b*) from aniline by the action of allyl iodide (in the cold), forming

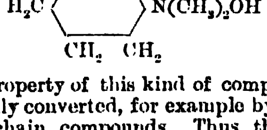
acting on the allyl aniline with benzyl chloride forming benzylallyl aniline,



and acting on the latter with methyl iodide, yielding



Although the iodides so prepared have the same chemical composition, they differ widely in physical properties; *e.g.* in melting point (dissociation point), specific gravity, crystalline form—they are isomeric. The chloroplatinate of methyldiethylisobutylammonium exists in two isomeric forms. Various explanations of this kind of isomerism have been advanced, but none is completely satisfactory. The isomerism does not occur with simple radicals; thus trimethylisobutylammonium salts show isomerism, but trimethylpropylammonium salts and dimethyldiethylammonium salts do not show isomerism. When the four organic radicals attached to the nitrogen atom are all different, the compound can be resolved into dextro-rotatory and lævo-rotatory forms: thus *a*-benzylphenylallylmethylammonium hydroxide (the compound prepared by method *a* given above) can be resolved by means of *d*-camphorsulphonic acid into its optically active components, the dextro rotatory ammonium compound of the sulphonic acid being less soluble than the lævo-rotatory compound. As quaternary ammonium compounds are considered those compounds where two of the four radicals R_1, R_2, R_3, R_4, are replaced by a ring; *e.g.*



A general property of this kind of compound is that they are easily converted, for example by distillation, into open chain compounds. Thus the dimethylpiperidinium hydroxide of the above formula gives Δ_4-pentenedimethylamine,

$$CH_2 : CH . CH_2 . CH_2 . CH_2 . N(CH_3)_2$$

Quarter Partition (*Build.*) A lath and plaster partition.

Quarter Plate (*Photo.*) A plate measuring $4\frac{1}{4}$ in. by $3\frac{1}{4}$ in.

Quarter Pyramid (*Min.*) One of the four pairs of faces making up a pyramid form of the Triclinic System.

Quarter Rip Saw (*Carp.*) Another name for a HAND SAW. *See* SAWS.

Quarters of the Moon (*Astron.*) When only one half of the illuminated portion of the lunar surface is visible. There are first and last quarters.

Quarter Space Landing (*Build.*) A landing whose width is equal to that of the ***stairs*** only, as distinguished from a HALF SPACE LANDING which extends the full width of the ***staircase***.

Quartet, Quartett (*Music*). A composition for four voices or instruments. A string quartet is a musical composition for four stringed instruments, generally two violins (first and second), viola, and violoncello. The family of "strings," *viz.* violin, viola, violoncello, and double bass, is sometimes spoken of as the quartet of strings.

Quarto. In printing, etc., a sheet which when folded makes four leaves. In the smaller sizes the height and breadth are nearly the same. Abbreviation, 4to.

Quartz (*Geol.*) A rock constituent of considerable importance. It occurs (1) as a primary mineral of the acid eruptive rocks, (2) as a mineral of secondary origin due to the decomposition of silicates, (3) in the form of veins, (4) as a derivative mineral, *e.g.* in the form of quartz pebbles or quartz sand. Quartz is characteristic of rocks of terrigenous origin, *i.e.* it is absent from oceanic deposits.

—— (*Min.*) Silicon dioxide, SiO_2. Silicon = 46·67, oxygen = 53·33. Rhombohedral. Transparent to opaque. Pure Quartz is colourless, but it is frequently coloured by various impurities, appearing brown, red, yellow, green, violet, etc. It is a mineral of the widest distribution, occurring both as a rock constituent and in veins. Quartz veins or "reefs" are often of great size, and are the commonest carriers of gold in gold bearing districts. Quartz is frequently found in gangue metal in metalliferous veins. Pure Quartz of the variety Rock Crystal is used for the manufacture of spectacle lenses under the name "pebble," and more recently for light treatment in Medicine. Pure Quartz sand is used in the manufacture of the soluble silicates of sodium and potassium known as "water glass," and also for many other industrial purposes. The chief varieties of Quartz are Rock Crystal, Amethyst, Smoky Quartz or Cairngorm, Aventurine, Cat's Eye, and Ferruginous Quartz. Chalcedony, which is often classed with Quartz, is really a mixture of anhydrous and hydrous silica.

Quartz Fibres (*Phys.*) Fine fibres produced by rapidly drawing out a piece of quartz when fused in the oxyhydrogen flame. These fibres can be made thinner than any natural fibre (*e.g.* unspun silk), and on account of their strength and elasticity are used in very sensitive galvanometers, electrometers, and other instruments containing moving parts which require delicate suspension.

Quartzine (*Min.*) *See* CHALCEDONY.

Quartzite (*Geol.*) A very hard rock, originally consisting of clean quartz sand, which, as a result of later causes, has been compacted by the deposition of secondary quartz between, or on, the grains of sand. The depositing agent has been water containing the silica in solution, in most cases at a moderately high temperature, and charged with an alkali. Impure quartz sand, under the operation of the same causes, passes into greywacké (*q.v.*)

Quartzose. Consisting of or containing a large percentage of quartz. Thus there are quartzose gneisses, quartzose schists and quartzose rocks of derivative origin.

Quartz Porphyry (*Geol.*) An eruptive rock of acid composition, in which blebs of quartz occur in a stony or lithoidal ground mass. Potash felspar is usually present.

Quartz Trachyte (*Geol.*) A synonym of LIPARITE (*q.v.*)

Quasi (*Music*). As if; somewhat; in the style of; as *quasi allegro*, somewhat cheerfully; *quasi sonata*, in the style of a sonata, *i.e.* in irregular sonata form.

Quassia (*Botany*). The wood of the West Indian trees *Picrasma excelsa*, *Quassia amara* (order, *Simarubaceæ*), furnish the Quassia wood. It is used as a bitter tonic.

Quatrefoil (*Architect.*) A cusped opening in Gothic tracery, formed with four foils or spaces between cusps. *See* CUSP, FOIL, TREFOIL, CINQUEFOIL, *and* MULTIFOIL.

—— (*Her.*) A plant with four leaves joined at a common centre, but without stalk. A figure formed of four leaves joined together at a common centre.

Quattro Cento (*Art*). Literally 400, but used as an abbreviation of 1400 (*Cf* CINQUECENTO). A term applied to Italian art, architecture, literature, etc., of the fifteenth century.

Quaver (*Music*). The name of one of the notes and rests. *See* NOTES—RESTS.

Quebracho Bark (*Botany*). The bark of several American trees, *e.g. Aspidosperma Quebracho* (order, *Apocynaceæ*), is imported from Argentina; it contains a number of alkaloids, amongst them ASPIDOSPERMINE, and is used medicinally and in leather tanning.

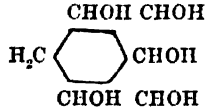
Queen Post (*Build.*) One of the vertical members of a queen post truss. *See* ROOFS.

Queens (*Build.*) (1) Roofing slates measuring 36 in. by 24 in. (2) QUEEN POSTS (*q.v.*)

Quenching (*Eng.*) The sudden cooling of steel by plunging it into water when redhot, whereby it becomes extremely hard.

Quercetin (*Chem.*) *See* FLAVONE.

Quercite (*Chem.*)



(Pentaoxyhexamethylene). Forms colourless prisms; melts at 234°; shows strong triboluminescence; sweet taste; soluble in water; less soluble in alcohol; insoluble in ether. It contains four asymmetric carbon atoms and should exist in twelve active and four inactive modifications. It is only known in one form, which is dextro-rotatory. On heating over 260° quinone, hydroquinone, pyrogallol, and other bodies sublime. It does not reduce Fehling's solution. On oxidation with manganese dioxide and sulphuric acid it gives quinone: with nitric acid it gives trioxyglutaric acid and mucic acid as well as oxalic acid. On reduction with hydriodic acid it gives benzene, phenol, pyrogallol, quinone, hexane, and hexylene. With nitric and sulphuric acids it yields a pentanitrate. It does not ferment with yeast. Quercite occurs in acorns, and is prepared from them. The acorns are extracted with cold water, the solution concentrated at 40° under reduced pressure, fermented with yeast to remove sugar, and treated with basic lead acetate; excess of lead is removed from the filtrate by sulphuretted hydrogen, and the solution is now crystallised: it is purified by recrystallisation from alcohol.

Quercitrin (*Chem.*) A glucoside. It is a yellow crystalline solid, slightly soluble in water; soluble in alkalis and in acetic acid. On boiling with dilute acids it is hydrolysed to rhamnose and quercetin. *See also* FLAVONE.

Quercitron Bark (*Botany*). A North American oak, *Quercus tinctoria* (order, *Cupuliferæ*), whose bark is used as a yellow dye. *See* DYES AND DYEING.

Quern (*Archæol.*) A primitive form of handmill consisting of two circular stones, the upper one fitted with a handle; used for grinding corn and other substances.

Queue (*Her.*) The tail of an animal.

Quick Curve. A curve of small radius.

Quick Gear, etc. (*Eng.*) Any gearing which produces a more rapid motion than the normal or working motion is often described as "quick."

Quicklime. Lime before being slaked; *i.e.* calcium oxide, CaO, as distinguished from the same oxide when combined with water, $Ca(OH)_2$, known as SLAKED LIME. *See* CALCIUM *and* CALCIUM COMPOUNDS.

Quick Return (*Eng.*) Some form of mechanism in machine tools for causing the return stroke (during which the cutting tool is not acting) to be performed more rapidly than the forward or cutting stroke.

Quicksilver (*Min.*) *See* MERCURY.

Quick Vinegar Process (*Chem.*) The process for making vinegar from malt liquor described under acetic acid (*q.v.*)

Quietamente, Quieto (*Music*). Quietly.

Quill (*Silk Manufac.*) *See* PIRN.

Quillaia. *See* QUILLAJA.

Quillaja *or* **Quillaia** (*Botany*). A South American genus of Rosaceæ. *Q. Saponaria* yields the soap bark of Chili, used in pharmacy.

Quinaldine (*Chem.*) Another name for *a*-METHYLQUINOLINE. *See* QUINOLINE.

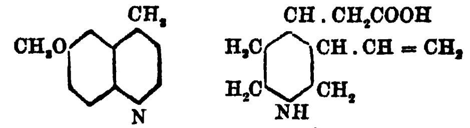
Quincunx. An arrangement of five objects so that four of them occupy the corners of a rectangle, the fifth being placed in the centre. A group of trees so arranged.

Quinic Acid (*Chem.*) $C_6H_7(OH)_4COOH$ (Hexahydrotetrahydroxybenzoic acid). A white crystalline solid; melts at 162°; very soluble in water, less soluble in alcohol, nearly insoluble in ether; lævo-

rotatory. When boiled with water and lead dioxide it gives hydroquinone: distilled with manganese dioxide and dilute sulphuric acid it gives quinone. It is reduced to benzoic acid by hydriodic acid. It is the acid or one of the acids with which the alkaloids are united in cinchona bark. To obtain it the bark is extracted with dilute sulphuric acid, precipitated by milk of lime, filtered, and the filtrate evaporated. The residue is extracted with alcohol—calcium quinate remains: it is purified by recrystallisation from water and decomposed by oxalic acid.

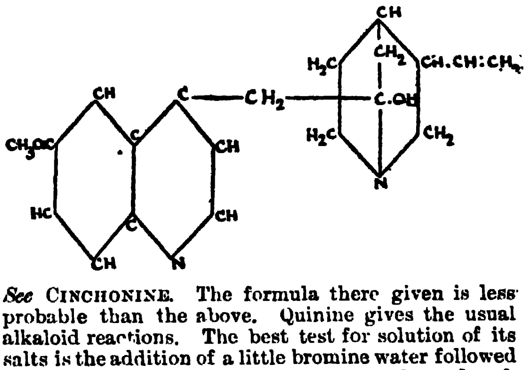
Quinine (*Botany*). This important alkaloid and its salts are obtained from the bark (Peruvian bark) of various species of *Cinchona* (order, *Rubiaceæ*). *See* CINCHONA.

—— (*Chem.*) $C_{20}H_{24}N_2O_2$. Forms white silky needles; where quinine is precipitated from solutions of its salts by ammonia and allowed to stand, the crystals contain three molecules of water; the anhydrous quinine melts at 175°, the hydrated quinine at 57°; it is sparingly soluble in cold water (1 part anhydrous quinine in 1,960 parts of water at 15°); much more soluble in alcohol, ether, chloroform, and hot benzene. Quinine is lævo-rotatory. It occurs in Cinchona Bark and in Remijia Bark. To obtain quinine the cinchona bark is boiled with dilute sulphuric acid, the solution is precipitated with caustic soda solution, the precipitate is dissolved in rectified spirit, neutralised with sulphuric acid, and the alcohol distilled off; crude quinine sulphate crystallises out, it is purified by recrystallisation, being less soluble than the other alkaloid sulphates. From the sulphate, quinine is separated by ammonia or caustic soda. *Salts:* Quinine is a diacid base, and so forms two series of salts—namely, basic salts, which have a neutral reaction, and normal salts, which have an acid reaction. In the following formulæ B stands for one molecule of quinine. The neutral sulphate $B_2H_2SO_4 8H_2O$, commonly called quinine sulphate, is the most important salt; it is a light, silky looking crystalline solid, sparingly soluble in water (1 part in 800 parts water), but readily soluble in water containing a little sulphuric acid when it forms the acid sulphate; the solution shows a blue fluorescence. When the neutral sulphate is dissolved in water containing one molecular proportion of sulphuric acid, alcohol added, brought to boiling, and treated with hydriodic acid and iodine (2HI + 4I), there is deposited on slow cooling a lustrous green crystalline (leaves) solid of the formula $B_4(H_2SO_4)_3(HI)_2I_4 6, H_2O$, called Herapathite. This substance has the remarkable property of polarising light about four times as strongly as tourmaline. The chlorides have the formulæ $B . HCl 2H_2O$ and $B2HCl$.; they are more soluble than quinine sulphate. Many other salts are known, but those mentioned are the ones used in medicine. Thus tincture of quinine contains the hydrochloride, ammoniated tincture of quinine contains the sulphate, ammonia, and alcohol. Quinine solutions have a very bitter taste; they are used in medicine as stomachics and as a preventive and cure for malaria; they are also good antiseptics. *Constitution:* Quinine is methoxycinchonine. *See* CINCHONINE. It is a ditertiary base because it adds on two molecules of methyl iodide; it is an alcohol, as it unites with acid chlorides and anhydrides to form esters; it is unsaturated, as it adds on two atoms of bromine or a molecule of hydriodic acid. When quinine hydrochloride is treated with phosphorus pentachloride it yields a quinine chloride—a hydroxy group is replaced by chlorine. This chloride on boiling with alcoholic potash loses hydrogen chloride and forms quinine. Quinine when heated with phosphoric acid yields paramethoxylepidine and meroquinine:



Paramethoxylepidine. Meroquinine.

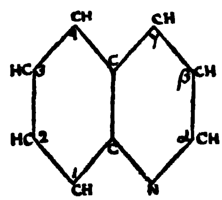
When quinine is oxidised with chromic acid, meroquinine is among the products; another product is quininic acid, which is the carboxylic acid corresponding to paramethoxylepidine (CH_3 changed to COOH). The constitution of meroquinine is fairly well established. On these grounds the formula for quinine is probably



See CINCHONINE. The formula there given is less probable than the above. Quinine gives the usual alkaloid reactions. The best test for solution of its salts is the addition of a little bromine water followed by ammonia, when a bright green colour is produced. The blue fluorescence of the sulphate is very characteristic.

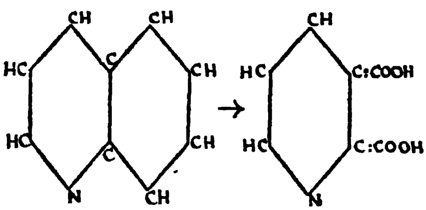
Quinol (*Chem.*) Another name for HYDROQUINONE (*q.v.*)

Quinoline (*Chem.*)



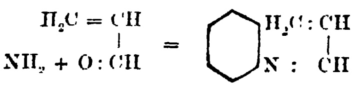
A colourless liquid; boils at 239°; it has a characteristic smell; nearly insoluble in water, readily soluble in the ordinary organic solvents; it is a strong antiseptic. It occurs in bone oil and in coal tar, and is formed when certain alkaloids, *e.g.* cinchonine, quinine, strychnine, are distilled with caustic potash. It is prepared by heating together aniline (38 grms.), glycerine (120 grms.), concentrated sulphuric acid (100 grms.), and nitrobenzene (24 grms.) The heating is done in a flask with reflux condenser; at first the temperature is kept for several hours at about 125°, then raised from 180° to 200°, till all reaction is over Water is added and the product boiled to drive off excess of nitrobenzene. Caustic soda is now added till strongly alkaline, and the mixture is distilled in steam. Aniline is present, and is removed by acidifying the distillate with sulphuric acid and adding sodium nitrite to convert the aniline to diazo-sulphate, which

is converted to phenol on boiling. The liquid is now made alkaline and again distilled in steam, the distillate is extracted with ether, dried over caustic potash, the ether distilled off, then the quinoline is distilled over. This method of preparing quinoline is known as Skraup's synthesis, and the reaction is a general one. *See below.* Quinoline forms salts with acids, *e.g.* $C_9H_7N.HCl$. This hydrochloride forms a double salt with platinic chloride; of the other salts the dichromate, which is very sparingly soluble in water, is important, $(C_9H_7N)_2H_2Cr_2O_7$. It also combines with many salts, *e.g.* with mercuric chloride. As a tertiary base it unites directly with alkyl iodides, forming quaternary ammonium iodides, *e.g.* with methyl iodide it forms methylquinolinium iodide, $CH_3C_9H_7NCH_3I$. On reduction with zinc and hydrochloric acid it forms tetrahydroquinoline—the pyridine ring being reduced; and when the tetrahydroquinoline is reduced with hydriodic acid and phosphorus the benzene ring is reduced, forming decahydroquinoline, $C_9H_{18}N$. When oxidised by potassium permanganate in alkaline solution or in strong sulphuric acid solution the benzene ring is destroyed and $\alpha\beta$-pyridinedicarboxylic acid is formed.

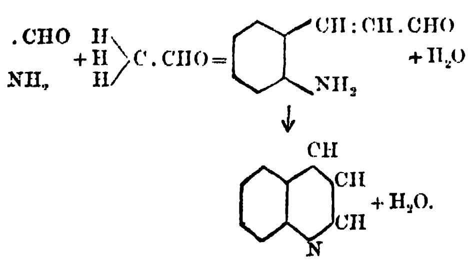


Quinolinic acid.

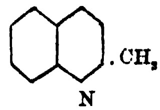
That quinoline has the formula assigned to it is shown by Skraup's synthesis; in this the glycerine is converted into acrolein by the sulphuric acid, and the acrolein condenses with the aniline:



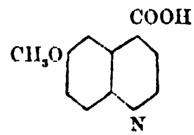
The nitrobenzene acts as an oxidising agent, furnishing oxygen, which unites with an atom of hydrogen adjacent to the nitrogen in the benzene ring and an atom of hydrogen from the methylene group, and thus brings about the ring formation. Another synthesis showing the constitution consists in condensing orthoamidobenzaldehyde with aldehyde in presence of caustic soda, forming orthoamidocinnamic aldehyde, which readily loses water and forms quinoline.



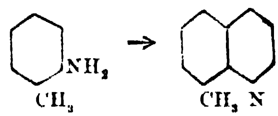
Quinoline derivatives are named by lettering the pyridine ring and numbering the benzene ring as shown in the formula for quinoline; then denoting the position of the substituent by its letter or number, naming the substituent and adding the name quinoline. Position 1 is sometimes called the ortho-position, 2 the meta-position, 3 the para-position, and 4 the ana-position with respect to the nitrogen atom. A number of quinoline derivatives have special names. Examples:



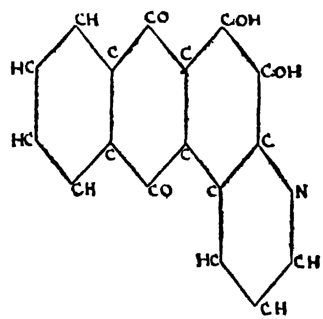
is α-METHYLQUINOLINE—also called QUINALDINE. γ-METHYLQUINOLINE is called LEPIDINE (*q.v.*)



is PARAMETHOXYQUINOLINE-γ-CARBOXYLIC ACID; also called QUININIC ACID. *See* QUININE. Quinoline derivatives can be synthesised (1) by Skraup's synthesis, using in place of aniline any substituted aniline, naphthylamine or substituted naphthylamine, etc., provided an ortho-position to the amido group is vacant. *E.g.* orthotoluidine would give orthomethylquinoline.

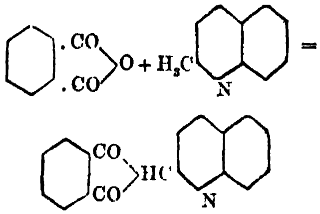


Skraup's synthesis is employed technically in the preparation of alizarine-blue—in fact, it was this preparation which led to its application to the synthesis of quinoline. Alizarine blue,



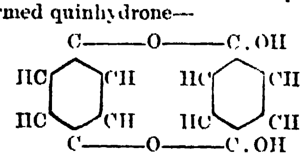
dihydroxyanthraquinonequinoline, is made by heating β-nitroalizarine with glycerine and sulphuric acid: it forms lustrous brownish violet needles, insoluble in water, slightly soluble in alcohol, and is a weak base; it is used chiefly in the form of its sodium bisulphite compound as a blue dye. (2) By heating together aniline, aldehyde, and concentrated sulphuric or hydrochloric acids. This synthesis is general, and various anilines, aldehydes, or an aldehyde and a ketone can be used; *e.g.* aniline and ordinary aldehyde give quinaldine. Quinaldine when heated with phthalic anhydride and zinc chloride

gives quinoline yellow, which is used in colouring wax and varnish.

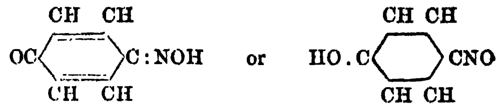


Other quinoline dyes are: Cyanine, a blue dye of unknown constitution obtained from molecular proportions of quinoline and lepidine by the action of amyl iodide and subsequent treatment of the product with caustic soda—used in photography. Quinoline red, obtained by the action of benzotrichloride, $C_6H_5CCl_3$, on a mixture of quinaldine and isoquinoline in presence of zinc chloride, is also used in photography.

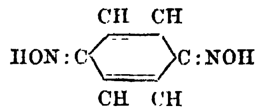
Quinone (*Chem.*)  (Parabenzoquinone). Yellow prisms; melts at 116°; readily sublimes; sparingly soluble in cold water; readily soluble in hot water, in alcohol, and in ether. It has a characteristic penetrating smell. Volatile in steam. Quinone is made by the oxidation of aniline; the aniline is dissolved in dilute sulphuric acid, cooled to 0°, and a strong solution of sodium dichromate added gradually and with constant stirring, keeping the temperature below 10°. After twelve hours a further addition of sodium dichromate (twice as much as before) is made, and the mixture again allowed to stand several hours. The quinone is now extracted with successive large quantities of ether, shaking gently to avoid the formation of a troublesome emulsion. The ether is distilled off, and the quinone distilled over in steam. Another method is to oxidise para-amidophenol sulphate in aqueous solution with lead dioxide and sulphuric acid; extract with ether, and so on as before. Many other paradisubstituted benzene derivatives yield quinone on oxidation. Quinone is an exceedingly active compound chemically; some of its reactions are as follows: It is easily reduced to hydroquinone, *e.g.* acidified potassium iodide reduces it with liberation of iodine; sulphurous acid reduces it. As an intermediate product of its reduction to hydroquinone, there is formed quinhydrone—



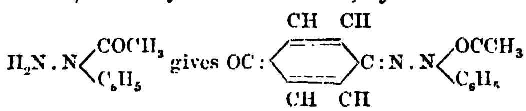
a lustrous green crystalline solid, which is also formed by direct union of quinone and hydroquinone. Chlorine converts quinone into a mixture of trichlor and tetrachlorquinone (chloranil). Its behaviour towards those reagents which act on ketones (*q.v.*) is as follows: (*a*) With hydrocyanic acid it forms 2 : 3-dicyanhydroquinone. (*b*) With hydroxylamine it yields both a monoxime and a dioxime; the monoxime is identical with nitrosophenol (*see* NITROSO COMPOUNDS), so that its formula is—



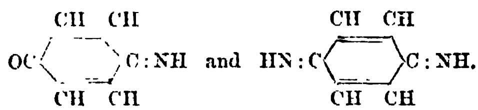
The dioxime has the formula



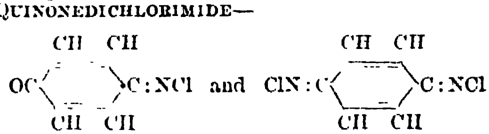
(*c*) With phenylhydrazine it does not give a hydrazone, but is reduced to hydroquinone; if the phenylhydrazine has a hydrogen atom replaced by an acid radical, then a hydrazone is formed, *e.g.*



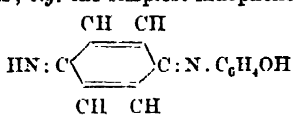
(*d*) With phosphorus pentachloride it gives paradichlorbenzene. Quinone has many important derivatives. Among them may be mentioned: (1) MONIMINOQUINONE and DIIMINOQUINONE—



They are obtained by oxidising para-aminophenol and paraphenylenediamine respectively in ethereal solution with dry silver oxide in presence of anhydrous sodium sulphate to take up water. They are both colourless compounds, and the moniminoquinone is explosive. (2) QUINONEMONOCHLORIMIDE and QUINONEDICHLORIMIDE—

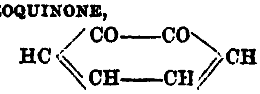


are crystalline solids, which melt at 85° to 124°, and are formed from para-amidophenol and paraphenylenediamine by the action of bleaching powder solution; the monochlorimide is also formed from aniline by hypochlorous acid. The quinoneimides may be regarded as the parent substances of a number of dyes. Thus salts of diiminoquinone form with aromatic amines, and with phenols Indamines (*q.v.*), and indophenols; *e.g.* the simplest indophenol is



(3) ANILIDOQUINONES: When aniline and quinone are boiled in alcoholic solution there is formed dianilidoquinone, $C_6H_2O_2(NHC_6H_5)_2$. The further action of aniline on this compound yields dianilidoquinonedianil, $C_6H_2(NC_6H_5)_2(NHC_6H_5)_2$, also called azophenine. It forms red leaflets, melts at 241°, is insoluble in alcohol and in ether, but soluble in benzene; it is formed in the preparation of indulines (*q.v.*), and is probably an important intermediate

product in the formation of this class of dyes. ORTHOBENZOQUINONE,



forms red plates; melts with decomposition at 60° to 70°, and is obtained by oxidation of orthodihydroxybenzene (catecohol) in dry ether solution by silver oxide. The name quinone is used in combination to denote other substances having a similar constitution to the ortho- and para-benzoquinones. For examples *see* ANTHRAQUINONE and NAPHTHAQUINONES. As all quinones are coloured (yellow or red), the groupings found in these substances are regarded as colour forming groupings: thus diacetyl, $CH_3 . CO . CO . CH_3$, has the orthoquinone grouping, and is yellow in colour. In accordance with this idea many dyes are written with "quinonoid" formulæ. *See, for example,* MALACHITE GREEN, PARAROSANILINE, NEUTRAL RED.

Quint (*Music*). An organ stop sounding the fifth above the open diapason. It is of 5⅓ ft. length on the manuals, and of 10⅔ ft. length on the pedals.

Quintet, Quintett (*Music*). A composition for five voices or instruments.

Quintuplet (*Music*). A group of five notes in the time of four.

Quintuple Time (*Music*). One that has five beats in a bar. *See* TIME.

Quire (*Paper Trade*). Twenty-four sheets of paper. *See* REAM.

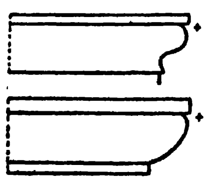
Quired Paper (*Paper Trade*). Sheets of paper folded in quires in contradistinction to paper sent out flat or lapped. *See* REAMS.

Quirewise (*Typog.*) Work printed as alternate pages on single leaves, and folded so as to allow of sewing instead of stabbing through.

Quirk (*Architect.*) An acute channel frequently used in Greek mouldings to separate an ovolo or a cyma reversa from the fillet above. It is also very commonly used in Gothic mouldings.

QUIRKED OGEE.

QUIRKED OVOLO.



—— (*Join., etc.*) The narrow groove at the side of a bead.

Quirk Router (*Join.*) A tool used in cutting a quirk (*q.v.*); it consists of an iron stock resembling that of a spokeshave, with movable cutters or quirking irons of various sizes to suit the width of groove required.

Quoin (*Build., etc.*) An external angle of a wall or building. A corner stone or one that serves to form an angle. A wedge-shaped implement or piece of material.

—— (*Typog.*) A small wedge used in locking up a forme (*q.v.*)

Quotation (*Typog.*) A phrase transcribed from a speaker or author in his own words, and indicated by having two inverted commas at the commencement and two apostrophes at the close, as: "The art preservative of arts."

Quotation Quadrats (*Typog.*) Large metal "spaces" of different bodies used for making up blanks and short pages, and usually cast hollow.

R (*Elect.*) The symbol for RESISTANCE (*q.v.*)

ρ (*Phys.*) A symbol generally used for DENSITY.

R.A. (*Astron.*) RIGHT ASCENSION (*q.v.*)

Rabbet *or* **Rebate** (*Build.*) A groove or slot on the edge or face of a flat surface. It is intended to receive the end or edge of another piece of material. A rectangular recess along a projecting angle, *e.g.* one to receive the edge of a door.

Rabbet Plane (*Join.*) A plane for working a right angled recess or groove on the edge of a piece of wood.

Rabbia, Con (*Music*). With fury.

Rabble (*Met.*) The flat ended but hooked bar used by puddlers in working the charge of iron, as contrasted with the "paddle," which is a straight chiselled edge bar, much the same as the "peeler" used for placing "piles" (*q.v.*) in the reheating or balling furnace.

Rabbling (*Met.*) The process of stirring the fluid iron during puddling (*q.v.*) The long iron rod bent at the end, with which the operation is effected, is termed a RABBLE (*q.v.*)

Race (*Eng., etc.*) (1) The open channel leading water to a water wheel, etc. (2) The path along which the shuttle travels in a loom. *See* RACE BOARD. (3) The space in which a drum or the flywheel of an engine revolves. (4) The path of the rollers or balls in anti-friction bearings, *e.g.* in a cycle wheel.

Race Board (*Weaving*). The smooth board fixed on the loom sley over which the shuttle traverses.

Raceme (*Botany*). An inflorescence in which the main axis bears stalked flowers and is capable of continued growth, adding new flowers in the apical region. An example is seen in the Currant.

Racemic Acid (*Chem.*) A form of tartaric acid composed of equal quantities of dextrotartaric and lævotartaric acids. *See* TARTARIC ACID.

Racemic Form or Modification (*Chem.*) *See* STEREOISOMERISM.

Racer (*Eng.*) A term sometimes applied to certain parts of machines which move with very great velocity.

Racing (*Eng.*) Uncontrolled increase in the speed of an engine when the governor (*q.v.*) fails to act properly. In marine engines racing occurs if the screw propeller is lifted out of the water by the motion of the vessel in rough weather.

Racing Cycles (*Cycles*). Very light cycles fitted with thin tyres, rat trap pedals, and very small saddles.

Rack (*Eng.*) (1) A bar, either straight or slightly curved, with gearing teeth cut on it, employed for converting rectilinear into circular motion, or the contrary. (2) A very general term for an object with a series of projections or equidistant parts of any description in machines, etc.

—— (*Lace Manufac.*) A unit of measurement employed in the manufacture of lace by machinery, *viz.* 240 holes or meshes of net. The system of measurement by which the Twist hand or working lacemaker is paid and by which lace is usually sold when in the "web" or "brown."

—— (*Typog.*) A fixture with grooves or runners for holding formes, cases, boards, etc.

Rack and Pinion (*Eng.*) A device for converting the rotary motion of a shaft into linear motion by means of a small toothed wheel or pinion keyed on the shaft, and gearing with a rack. Frequently used in mechanism.

Rack Back (*Build.*) In building a wall it is sometimes necessary to leave a portion of it unfinished. When this is the case every course is started $2\frac{1}{4}$ in. back from the unfinished part. This is to prevent unequal settlement when the wall is finished.

Racking (*Build.*) A term signifying distortion. If a piece of framing is moved out of shape, it is said to be racked.

—— (*Chem. Manufac.*) The process of running spirit from one vessel to another, so as to expose it to the action of the air in order to promote oxidation, etc. It facilitates the "ageing" of spirit.

—— (*Mining*). The separation of ores, etc., by washing them on a sloping surface.

—— (*Surveying*). *See* SURVEYING.

Rack Rail (*Eng.*) The toothed rail used in certain forms of MOUNTAIN RAILWAY (*q.v.*)

Raddle (*Build., etc.*) Wattled work, *e.g.* a hurdle formed of supple sticks or boughs intertwined between stout upright sticks. A similar structure, formed of laths, and daubed or plastered with clay, is sometimes used to form a wall.

—— (*Weaving*). A coarse kind of sley or reed (*q.v.*), but usually made of wood. Between the pins or pegs the threads of warp are passed in groups in running the warp on to the warp beam or roll.

Raddolcendo (*Music*). Increasing in softness.

Radial Arm (*Eng.*) A projecting lever or arm, pivoted at one end, and usually carrying some mechanism, as in a RADIAL DRILLING MACHINE (*q.v.*)

Radial Drilling Machine (*Eng.*) A drilling machine in which the drill spindle is carried on a projecting arm which can rise and fall or swing round in a horizontal plane, thus allowing the drill to be brought into different positions over the piece of work.

Radial, Radially. Having the direction of a radius, *e.g.* lines, etc., diverging from a centre.

Radian (*Math.*) The unit angle in the system of CIRCULAR MEASURE (*q.v.*)

Radiant (*Astron.*) A point from which the paths of a number of meteors appear to diverge.

—— (*Phys.*) Acting as a source of radiation. The term is sometimes applied to the source itself, *e.g.* the light used in an optical lantern is termed the Radiant.

—— *or* **Rayonné** (*Her.*) A charge or ordinary having rays issuing from the edge.

Radiant Heat. Heat which passes from a hot body or source through an intervening medium which transmits, but does not absorb it. Heat, or, more correctly speaking, radiant energy, travels from the sun to the earth in this manner through the ether, and appears as heat when it falls on a body which absorbs it.

Radiation (*Phys.*) A term denoting the emission of energy from a body.

LIGHT AND HEAT RAYS: In this case the energy takes the form of wave motion in the surrounding ether, originated by the molecular vibrations of the radiating source, and does not become heat or produce the sensation of light until it falls upon a body which absorbs it, or upon the retina of the eye. The process of warming by radiation, as the earth by the sun, thus differs from other possible methods of transferring heat energy, in the fact that the temperature of the intervening space is not affected by the transmission, and is quite independent of that of the source or the receiver. Ether waves only differ from one another in the rapidity of the vibrations; the slower they are the greater the wave length, and *vice versâ.* The waves emitted from a hot solid body are a very complex mixture of different wave lengths, dependent not only upon temperature, but usually also on the nature of the body—that is, some wave lengths are emitted in greater proportion than others. According to modern ideas regarding the structure of matter, all bodies above absolute zero are sources of disturbance in the ether in which they are embedded. It is probably inaccurate to regard the molecular vibrations themselves as originating waves, for ordinary matter moves freely in ether without getting any "grip" on it; it is most likely the oscillations of the attached electric charges or "electrons" which are effective, their period, however, being governed and controlled by the molecules to which they are attached. The properties of the waves thus produced are functions of their period or wave length. Very long waves of slow period, of lengths, say, half inch and upwards, are most easily produced by electrical methods, and are applied to useful purposes in Wireless Telegraphy. The radiation from heated bodies has been traced experimentally through a range of wave length extending from about $\frac{1}{400}$ to $\frac{1}{250000}$ in. At about $\frac{1}{32000}$ in. they become capable of producing the sensation of red light, the greatest heating effect being produced by invisible waves somewhat longer than these. When $\frac{1}{63000}$ in. is reached for the extreme violet the radiation again becomes invisible, and within this range the heating effect has rapidly decreased and the power of producing fluorescence, phosphorescence, and chemical action has increased with equal rapidity. The general laws of radiation were discovered during the earlier and middle part of the last century by Leslie, Melloni, Forbes, Tyndall, and others. Their investigations established the fact that good radiators are also good absorbers, and *vice versâ,* and also that a body when cool absorbs most readily those wave lengths which it most readily emits when hot. But as their methods dealt with complex sources of radiation as a whole, and as these properties vary in general with wave length, no exact quantitative results were obtained. Probably the greatest advance which has been made since the days of the early experimenters has been in the direction of sorting out radiation and dealing with particular wave lengths individually, and also in the conception and realisation of the "absolute black body." Black surfaces possess the property of absorbing or radiating all waves with almost equal freedom; but even lampblack reflects and diffuses some of the radiation which falls upon it, and it becomes therefore possible to imagine an ideal substance which shall neither reflect, diffuse, nor transmit, but completely absorb all the incident waves of whatever kind. The properties of such a body can be investigated mathematically, and among other important results it has been established:

(1) The radiation from it depends only upon its temperature and the refractive index of surrounding

medium, and is quite independent of its nature or physical state.

(2) The energy value of the total radiation emitted per unit area in unit time is proportional to the fourth power of the absolute temperature.

(3) At any given temperature there is one particular wave length which conveys the maximum energy, and this wave length is inversely proportional to the absolute temperature.

(4) The amount of radiation of this particular wave length, for which the energy is a maximum, varies as the fifth power of the absolute temperature,—really a deduction from (2) and (3).

These results afford several methods of measuring very high temperatures, and have been repeatedly verified. No actual substance could satisfy the mathematical requirements of absolute blackness; but a small hole in an enclosure kept at constant temperature realises it in practice, for very little incident radiation is reflected out of it again, and it can be shown to emit the full radiation for that particular temperature. As regards ordinary bodies, it may be said that the higher the temperature the more closely they approximate to the behaviour of the ideal black body.

LIGHT WAVES: It follows from what has been said that light rays differ in no way from other ether waves, except in their special power of stimulating the visual organs, and may form an altogether insignificant fraction of the total emission from a hot body. Their discussion as radiation belongs to the Theory of Light; here it is sufficient to say that solid incandescent bodies give a continuous spectrum, *i.e.* emit waves of all lengths within a certain range, the maxima extending further into the violet as the temperature rises, in accordance with the radiation law (3) already given. Gases and vapours do not usually become luminous by merely rising in temperature; but when caused to emit light by any suitable stimulus, they give, under ordinary conditions, discontinuous spectra, *i.e.* there is selective radiation and consequently there is selective absorption—a fact upon which the whole science of Spectrum Analysis is founded.

PRESSURE OF RADIATION: According to the theory of light there must be a pressure upon any surface due to incident radiation, that due to normal incidence upon a completely absorbent surface being numerically equal to the energy of the wave per unit volume. For a perfectly reflecting surface its value would be twice as great. The absolute value of this pressure is very small (about $4{\cdot}1 \times 10^{-5}$ milligrams weight for sunlight); but it has been detected experimentally by Lebedew, and the results confirmed by Nichols, and in the case of very small particles it may be greater than gravitation. Poynting has detected experimentally the tangential forces which exist in the case of refraction. This pressure of radiation is of great importance in the theory of the absolute black body.

SOLAR CONSTANT: This is the amount of energy (expressed in gram-centigrade heat units) received by 1 square centimetre per minute at the earth's distance from the sun, assuming no atmosphere present. Its value lies probably between 3 and 4. At least 40 per cent. of this energy is intercepted by the atmosphere. A simple calculation shows that the energy radiated per square centimetre per minute from the sun's surface is 460,000 times as much, which works out to about 17 horse power.

CATHODE, LENARD, AND RÖNTGEN RAYS: The first two of these are not radiation in the ordinary sense (not being ether waves), but may be dealt with conveniently here as special cases of emission of energy. Cathode rays are given out by the negative terminal of a vacuum tube at very high exhaustions (of the order of one-millionth of an atmosphere). They were first noticed by Plücker and Hittorf, and afterwards carefully studied by Crookes. This radiation is easily shown to issue normally from a cathode, and to behave as if it were a stream of material particles carrying negative charges and moving with very high velocities (which may amount to from $\frac{1}{10}$ to $\frac{1}{3}$ of the velocity of light). This stream possesses inertia, being capable of turning vanes and of heating the surfaces on which it falls, and many substances become brilliantly phosphorescent with characteristic colours when exposed to its impact. Finally, these properties are completely independent of the nature of the matter present in the tube. Lenard covered a small hole in the tube with very thin aluminium (following up an observation due to Hertz), and found that when a stream of cathode rays fell upon it, something feebly luminous passed through into the outside air which could excite phosphorescence and produce feebly most of the effects of cathode rays, but which became speedily dissipated and lost except close to the origin. It was, in fact, cathode rays which had penetrated the aluminium, and which were found to be capable of penetrating any kind of matter if only thin enough, being stopped by substances roughly in the order of their densities. The study of cathode rays inside the tube naturally suggested the idea of material particles, while, on the other hand, the fact that their properties were independent of the nature of the matter used, and the remarkably penetrating nature of the Lenard rays in air seemed to contradict this hypothesis, for no ordinary atom could move a fraction of an inch in air without being stopped and diverted by frequent collisions. Hence arose two schools of thought, the English physicists on the whole regarding them as charged particles, whilst Lenard and his followers considered them to be a particular kind of ethereal disturbance independent of ordinary matter. Finally, J. J. Thomson, in a most brilliant series of measurements, showed that the cathode stream consists of negatively charged particles having only about $\frac{1}{700}$ of the mass of the hydrogen atom, and which, although derived from ordinary matter, are certainly not matter in its ordinary sense. This result, together with their high velocity, explains their penetrating power, and constitutes an epoch in our knowledge of the structure of the atom. Röntgen discovered that when cathode rays are suddenly stopped by striking an obstacle, a new and still more penetrating kind of radiation emanates from the point struck, which, although invisible to the eye, can pass through the glass of the tube and affect photographic plates or excite phosphorescence outside. Like Lenard rays, it is stopped by bodies roughly in the order of their densities, but differs from them in being perceptible at enormously greater distances from the tube. This radiation possesses conspicuously the power of strongly ionising air or other gases through which it passes, making them temporarily conductors. Further, it is incapable of being refracted or regularly reflected, and no definite results of the nature of interference or polarisation have been detected. The great range of these rays seems to exclude the idea of projected material particles, and they are generally supposed to be really a special kind of ether wave, not produced in regular vibrations, but as an irregular series of discrete

pulses produced by the shock of the impact of the cathode rays. The question would be practically settled by a determination of their velocity, but it is doubtful if this has really been successfully accomplished at present.—E. E. B.

Radiation, Solar (*Astron.*) Expressing this in energy, it is nearly 130,000 horse power continuously for each square metre of the sun's surface. The Earth receives only about $\frac{1}{2200000000}$ of the total radiation.

Radiator (*Build.*) A hollow frame or structure, generally of cast iron, through which steam, hot water, or hot air circulates. The heat is radiated into the apartment in which the structure is fixed, thus warming it. Where feasible, radiators should be fixed against an outer wall and be furnished with a device for admitting air from without; this becomes heated as it passes over the surface of the radiator, and keeps the atmosphere of the apartment fresh.

—— (*Eng.*) A device for dispersing heat by radiation; *e.g.* the apparatus by which the circulating water in a motor car is cooled. *See* MOTOR CAR *and* PETROL ENGINE.

Radical (*Chem.*) Literally the common stem or root of a number of different compounds. It is used occasionally of elements. Thus, when it is desired to refer to the metal in a series of salts of that metal, the metal might be spoken of as the basic radical. But the term is much more commonly used to denote a group of elements which reacts as if it were a single element; such groups are known as compound radicals, and have not an independent existence. Thus the group CN is the cyanogen radical, but it does not exist by itself. However, two such groups usually unite together to form a compound which can exist. Thus we have:

Methyl, CH_3	Ethane, CH_3-CH_3
Cyanogen, CN	Cyanogen, Gas, $CN-CN$
Phenyl, C_6H_5	Diphenyl, $C_6H_5-C_6H_5$

See also COMPOUND RADICAL *and* CACODYL.

Radicle (*Botany*). The descending portion of the axis of the embryo in a seed. It absorbs nutritive solutions from the soil, and also gives anchorage to the seedling. In most Dicotyledons the radicle develops into the main or tap root of the adult plant; but in Monocotyledons it is suppressed, and roots arise from the base of the stem.

Radio- (*Phys.*) Relating to rays or radiation, *e.g.* RADIOACTIVITY (*q.v.*)

Radioactivity (*Phys.*) The power possessed by certain substances of spontaneously emitting radiations capable of affecting photographic plates, exciting phosphorescence, and ionising the surrounding air.

In 1896 Becquerel discovered that uranium salts emitted something which could act upon a sensitive plate wrapped up in black paper, and which made the air around temporarily a conductor. He found that all salts of uranium, and also the metal itself, possessed these properties, which in no way depended upon previous exposure to light and were in no degree weakened by lapse of time. He also found that the radiations could not be reflected, refracted, or polarised, while researches by various experimenters showed that of the known elements only thorium possessed similar powers.

The next great step was made by M. and Madame Curie, who found that while all uranium minerals were active, their activity was not proportional to the amount of uranium they contained, and in some cases was even greater than that of the metal itself. This suggested that small quantities of some very active substance were present, and after much labour M. and Madame Curie were able to separate from PITCHBLENDE (a very complex ore of uranium) two intensely active substances now known as RADIUM and POLONIUM, the former being a definite element allied to Barium, and the latter a substance associated with bismuth, difficult to isolate and as yet of uncertain nature. Other radioactive bodies have been separated from pitchblende, but in quantities excessively small, and it is still doubtful how far they are really independent entities. Debierne obtained ACTINIUM, and Marckwald RADIO-TELLURIUM, while Hofmann and others have found an active substance present with lead derived from that mineral.

Radioactivity is detected either by its effect on a sensitive plate or by its power of discharging charged bodies, the latter method being by far the more delicate and reliable. It appears to be due to the gradual breaking up of a complex atom into simpler forms, accompanied by the emission of relatively enormous quantities of energy. Very little of this emitted energy is in the form of ordinary light or heat waves, although the emission keeps the source at a perceptibly higher temperature than its surroundings. It mainly consists of streams of charged particles projected with great velocities. Such a stream is deflected by magnetic and electric fields, and the amount of the deflection in the two cases determines the velocity and ratio of mass to charge of the flying particles. Three distinct types of radiation were soon recognised and distinguished as the α, β, and γ-rays respectively, all of which are given off by Radium and Thorium: whereas Polonium and Radio-Tellurium appear to give off mainly one kind, the α-rays.

The α-rays represent most of the radiated energy, and appear to be positively charged particles about twice as heavy as the hydrogen atom, and moving with velocities of about 20,000 miles per second. They excite phosphorescence in certain substances, especially Sidot's Blende (*q.v.*), and their ionising power is very great. They are only slightly deflected by a magnetic field, and are very easily stopped by slight obstacles, such as a sheet of paper.

The β-rays appear to be identical with Cathode rays. They consist of negatively charged particles much smaller than ordinary atoms, moving with velocities varying from about 50,000 miles per second to a speed closely approaching that of light itself. They are easily deflected by magnetic and electric fields, can excite phosphorescence, especially in Willemite, Kunzite, and barium-platinocyanide, and can readily penetrate obstacles which would entirely stop the α-rays. At the same time their ionising power is much less than that of the α-rays.

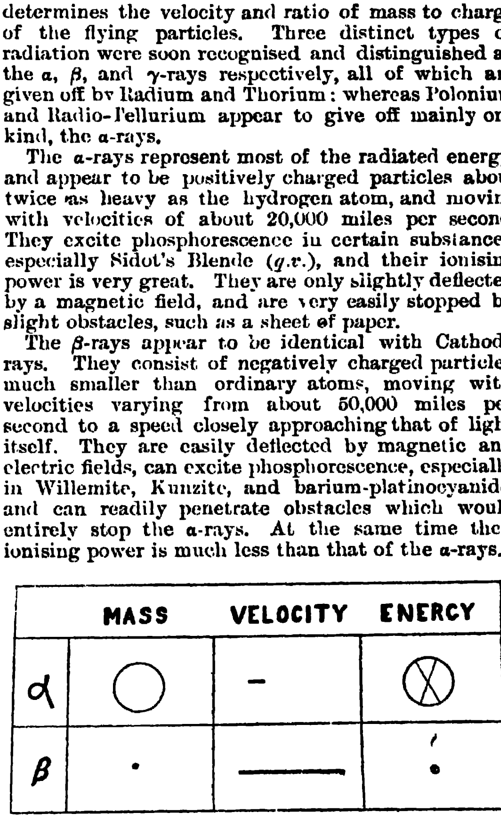


FIG. 1.

Diagram showing the mass, velocity, and energy of the α and β particles. The velocity is represented by the length of the lines in the middle column, the mass and energy by spheres.

The γ-rays do not appear to consist of material particles, as they are not deflected by magnetic or electric fields. They are probably a special kind of ether wave, *i.e.* of light, resembling X-rays, and are produced by the shock of starting the emitted particles, just as ordinary X-rays in a vacuum tube are produced by their sudden stoppage. Their chief characteristic is their remarkable power of penetration, in which respect they surpass the X-rays. They also possess the power of exciting phosphorescence and causing ionisation, but in the latter respect are less effective than the β-rays and enormously less effective than the α-rays.

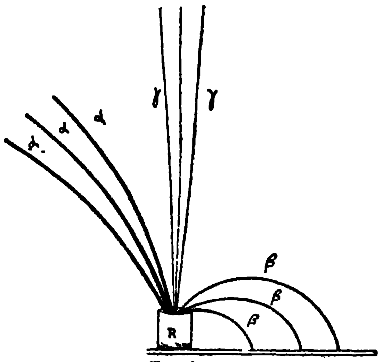

FIG. 2.

Diagram showing the deflection of the α, β, and γ Rays from Radium.

In addition to these typical forms, it has been recently shown by J. J. Thomson and others that there is also a copious emission of quite slow moving β-particles. These complex radiations are not emitted by Thorium, Radium, or Uranium themselves, but by substances continually being formed from them, and which by suitable means can be removed from the parent substance, leaving an inactive material which regains its radioactive power at a perfectly definite rate.

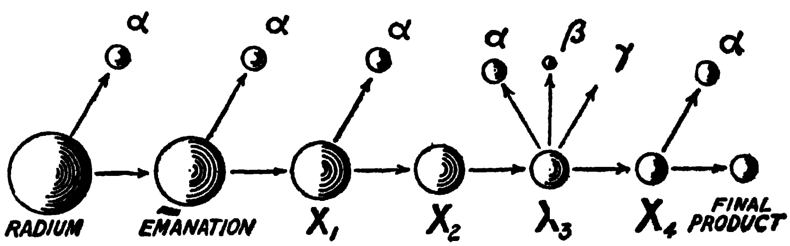

FIG. 4.

Diagram representing the disintegration of a Radium Atom.

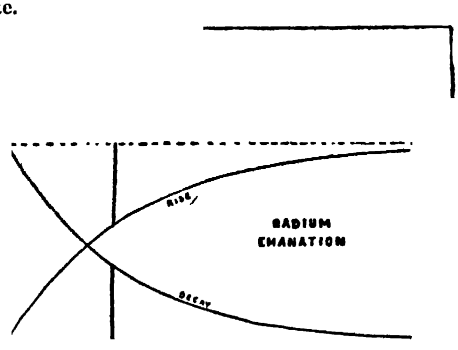

FIG. 3.

Curves showing the rate of decay of the activity of the emanation, and the recovery of activity of Radium.

Meanwhile the very active portion removed gradually loses its activity at exactly the same fate, differing for different substances, but always in a geometrical ratio with time. For this reason it is convenient to state the time required for the body to lose half its activity, for this is a definite period, whatever the initial strength may be. It will be sufficient here to trace the life history of radium as far as at present known.

The parent of radium is probably uranium, from which it is formed at a very slow rate—so slowly that this fact is as yet not definitely established. Radium itself does not appear to be radioactive, but in its turn slowly breaks up, giving off in minute amount an "emanation" (discovered by Rutherford first in the case of thorium), which mostly remains occluded in the parent radium salt, from which it can be removed by heating or bubbling air through a solution. This "emanation" appears to be an inert heavy gas, displaying no chemical activities, and absolutely unaffected at the highest temperatures. It can be liquefied by cold and pumped through tubes, and it apparently has a characteristic spectrum. It is intensely radioactive, its presence in glass tubes being indicated by the phosphorescence of the walls, and it supplies most of the heat emission of radium salts (according to Rutherford, if it were possible to collect a cubic inch, it would probably melt the glass tube containing it), and it appears to emit only α-particles. It loses half its activity in four days, which means that in that time half of it has changed into some other form. Apparently this change is due to the emission of the α-particle, and it now becomes "emanation X_1," a solid body which collects on surfaces exposed to the gaseous emanation, leaving them temporarily radioactive after the latter has been blown away. In three minutes half of this changes into "emanation X_2," also with the emission of α-particles. X_2 does not appear to emit any kind of particle; but every twenty-one minutes half of it changes into X_3, which in its turn breaks up rapidly (half in twenty-eight minutes), with the emission of α, β, and γ-rays. It is noteworthy that the β and γ-rays are only emitted during the last of these four rapid changes.

The next two stages occur very slowly, and have only recently been traced by Rutherford, who calls them provisionally D and E. The former only gives out β-rays, and is half transformed in about forty years into E (however, it may eventually turn out that two changes occur here instead of one). E gives out only α-rays, and is half transformed in about 150 days. Beyond this nothing is as yet known with certainty. These slow changing bodies should gradually accumulate in ores of radium, and it is possible that D may turn out to be the active constituent in Hofmann's radioactive lead, while E may be identical with the polonium of the Curies and the radio-tellurium of Marckwald. Only the first product of radium, the gaseous emanation, is

chemically inert. All the succeeding solid products have definite chemical and physical properties, which make it possible to identify and partially separate them. What the final products may be is as yet unknown; but it is certain that the rare gas HELIUM is one of them, and it may possibly be the projected α-particle itself. This formation of helium from radium (discovered by Ramsay and Soddy) is remarkable as being the first case known of one element changing partly into another. Evidence is rapidly accumulating which goes far to show that radioactivity is in various degrees a general property of matter, and not confined to a few very rare substances. Apparently the whole crust of the earth is more or less radioactive, and it seems probable that slow and gradual change into simpler forms is part of the life history of the atom.—E. E. B.

Radiograph. (1) An instrument for measuring and recording the intensity and duration of sunshine. (2) An image of some object produced on a sensitised plate by means of the Röntgen rays.

Radiolarian Ooze *and* **Radiolarian Chert** (*Geol.*) Large numbers of *Polycystinæ* (*Protozoa* with siliceous tests) live in the upper waters of the warmer parts of the ocean along with the *Foraminifera*, which secrete calcareous shells. When these die their shells descend together towards the ocean floor. But solution of the calcareous shells begins at a few hundred fathoms below the surface, and is generally completed by the time they have sunk to a depth of 2,500 fathoms. The siliceous shells of the *Radiolaria* or *Polycystinæ* then reach the bottom alone, *i.e.* without any calcareous matter. A deposit so formed is termed a Radiolarian Ooze. Ancient Radiolarian Oozes, now altered into more or less cherty rocks, occur in many geological formations, and bear important testimony to the former presence of oceanic conditions in areas which may now form parts of continents.

Radiometer, Crookes' (*Phys.*) A set of light metal vanes, fixed on a vertical axis so as to be capable of easy rotation, and enclosed in an exhausted globe. One side of each of the vanes is blackened, the other left bright. Radiant heat received by the vanes causes them to rotate at a rate depending on the intensity of the radiation.

Radio Micrometer (*Elect., etc.*) An instrument for the detection and measurement of small amounts of radiant heat. It consists of two small bars of metal forming a thermo-electric couple (*q.v.*), one end of each bar being attached to a small blackened copper disc on which the radiant heat is received, and the other ends connected together by a loop of copper wire. The whole arrangement thus forms a closed circuit, and is suspended by a quartz fibre in the strong magnetic field between the poles of a magnet such as is used in suspended coil galvanometers. Radiant heat falling on the disc heats the thermo-electric junction, causing a current to flow round the loop, and the whole circuit turns through an angle depending on the strength of the current, *i.e.* on the intensity of the radiation received. The instrument is extremely sensitive, and when used with a suitable reflector will detect the radiant heat received from a candle placed two miles away.

Radium (*Chem.*) Rd. Atomic weight, 225. A metal which occurs, in traces only, in pitchblende, carnotite, and a few other rare uranium-containing minerals. The pitchblende (*q.v.*) from Joachimsthal (Bohemia) contains more radium than any other variety. After the uranium has been extracted from this pitchblende, a ton of the residue yields 0·2 to 0·3 gram of radium bromide. The metal itself has not been prepared; but it amalgamates with mercury, as is shown by the fact that when a saturated solution of radium-barium chloride is shaken with a 1 per cent. sodium amalgam, a radium-barium amalgam relatively richer in radium than the original double chloride is formed, so that the metal could be prepared by means of its amalgam. *Cf.* BARIUM. A number of radium salts have been prepared, *e.g.* the bromide, chloride, nitrate, carbonate, and sulphate, and they resemble generally the corresponding barium salts; but the bromide and chloride are less soluble than those of barium, and of course no barium salt is radioactive. Radium bromide is prepared from pitchblende by the following method. The pitchblende is powdered and fused with sodium carbonate. Soluble salts are extracted with hot water, and the residue is treated with dilute sulphuric acid. The sulphuric acid solution contains the uranium. The insoluble residue, formerly a waste product, contains the radium; it is treated with concentrated hydrochloric acid. The solution thus obtained contains most of the polonium and actinium, while the insoluble part contains the radium in the form of sulphate. After washing with water, this residue is boiled with a concentrated solution of sodium carbonate, in order to transform the insoluble sulphates to carbonates; the carbonates are washed with water, then dissolved in dilute hydrochloric acid. This solution is again precipitated with sulphuric acid, and the resulting sulphate converted into chloride exactly as above. The solution of chlorides is now treated with sulphuretted hydrogen; the precipitate contains some polonium. The solution is boiled and oxidised by potassium chlorate, and treated with ammonia; the precipitate contains some actinium. The solution is precipitated by sodium carbonate, the precipitate is washed, dissolved in hydrochloric acid, evaporated to dryness, and the residue washed with concentrated hydrochloric acid to remove calcium chloride, and leave a residue of barium and radium chlorides. A little radium is removed by the washing with hydrochloric acid; it is precipitated by sulphuric acid, and the precipitate worked up with fresh material. The radium and barium chlorides are dissolved in water, precipitated by sodium carbonate, and the carbonates dissolved in hydrobromic acid. Eight to ten kilograms of mixed bromides result from 1,000 kilograms (2,204 lb.) of pitchblende, and it is about sixty times as active as uranium. The bromides are now submitted to fractional crystallisation, first from water, then from hydrobromic acid, the radium bromide being less soluble than the barium bromide. The most active bromide obtained is about two million times as active as uranium. Radium bromide crystallises in the monoclinic system, is deliquescent, and is therefore kept in sealed tubes; it gives a crimson colour to the Bunsen flame, and when this flame is viewed in the spectroscope it gives two lines in the red, one in the blue green, and two (faint) in the violet. On keeping, the radium bromide, which is pure white when fresh, becomes brown; but it can be made white again by heating. A solution of radium bromide in water evolves hydrogen and oxygen continually at the rate of 10 cc. of the mixed gases per gram of radium per day, the hydrogen always being rather more than double the volume of the oxygen. Radium salts convert yellow phosphorus into red phosphorus. When exposed to air, ozone is

produced; iodine is liberated from a solution of iodoform. They impart a brown violet colour to glass, blacken a diamond externally, also darken quartz. When a radium salt contained in a celluloid capsule is placed on the skin and left a while, its action can be felt, and some hours after its removal a red patch appears, then a wound, which takes a long time to heal. On this account radium salts have been applied to the cure of lupus. Attempts have been made to cure cancer by the application of radium salts, but without success. Radium salts cause a number of substances to fluoresce, especially barium platinocyanide, willemite (zinc orthosilicate), Sidot's blende (slightly impure zinc sulphide). A radium salt is feebly luminous in air, and the spectrum of this light has been shown to be that of nitrogen, but in an atmosphere free from nitrogen the spectrum is continuous. Radium is an element which is constantly undergoing spontaneous decomposition; its atom is not stable, but breaks up into simpler atoms. This decomposition differs from ordinary chemical decompositions in being entirely beyond the control of the chemist, who can neither accelerate nor retard it. The rate of this decomposition is such that a gram of radium bromide would be half decomposed in about 1,150 years; the nature of the decomposition is described under RADIOACTIVITY (*q.v.*) As radium has a comparatively short life, it follows that, in a mineral such as pitchblende, radium is constantly being produced. Its probable source is uranium, itself a radioactive element, but with a much longer life (2,000,000,000 years). There is little direct evidence bearing on this subject as yet; but it is noteworthy that the amounts of uranium and radium present in pitchblende are about as $10^9:10^3$. The physical behaviour of radium is described in the article on RADIOACTIVITY (*q.v.*) The atomic weight of radium has been determined by precipitating a solution containing a known weight of radium chloride with silver nitrate, and weighing the silver chloride so produced; the value obtained was 225 (O = 16). It has also been determined by comparing the frequency difference of the double lines in the two subordinate series of the radium spectrum with those of magnesium, calcium, strontium, and barium; the result is 257·8. The reason of this great difference is unknown. That radium is an element is shown by the fact that it falls into position in the periodic system (*q.v.*); it has chemical properties closely resembling those of barium, which is an element in the same group; it has a characteristic spectrum.

W. H. H.

Radius. In a circle, the distance from the centre to the circumference. *See also* RADIUS OF CURVATURE.

Radius of Curvature. If normals be drawn from two adjacent points on a curve, they will intersect in a point lying on the concave side of the curve. If the two points be now supposed to move towards one another, the point of intersection of the two normals will move towards a limiting position, which it will occupy when the two points from which the normals are drawn are upon the point of coinciding. The distance from the curve to the point of intersection of the normals is termed the RADIUS OF CURVATURE of the curve. The point of intersection is the CENTRE OF CURVATURE, and a circle drawn from this centre, touching the curve at the points from which the normals are drawn, is termed the CIRCLE OF CURVATURE of the given curve at the point of contact. It has at this point the same *slope* and the same *rate of change of slope* as the given curve.

Radius of Gyration (*Phys., etc.*) The Moment of Inertia (*q.v.*) of a body may in general be expressed in the form $K = mk^2$, where m is the mass; the quantity k is called the Radius of Gyration.

Radius of the Earth (*Astron.*) The mean or average radius is about 3,959 miles. Measured from the Pole to the centre it is 3,950 miles; from the Equator to the centre it is 3,963 miles. The earth is really an oblate spheroid, *i.e.* a solid produced by an ellipse revolving about its shorter axis.

Radius Rod (*Eng.*) Part of the Parallel Motion used in beam engines; now nearly obsolete.

Radius Vector (*Phys., etc.*) A line drawn from a fixed point to a particle or body moving under the influence of a force acting towards that point; *e.g.* the line drawn from a planet to the sun.

Raffia (*Botany*). The thin cuticle (or outer wall of the epidermis) of the leaves of a Madagascar palm, *Raphia ruffia* (order, *Palmæ*), used by gardeners for tying up plants, flowers, etc.

Raffinose (*Chem.*) $C_{18}H_{32}O_{16}$ (Melitose or Melitriose). A sugar which crystallises in shining needles or prisms containing 5 molecules of water of crystallisation. On slow heating at 80° to 105° it loses this water and forms an anhydride. Soluble in water; insoluble in alcohol; no sweet taste; its solution is dextrorotatory $[\alpha]_D = 404°$. On hydrolysis with dilute acids it yields dextrose, lævulose, and galactose:

$$C_{18}H_{32}O_{16} + 2H_2O = 3C_6H_{12}O_6.$$

On careful hydrolysis an intermediate stage occurs, lævulose splitting off first and melibiose being formed, $C_{18}H_{32}O_{16} + H_2O = C_6H_{12}O_6 + C_{12}H_{22}O_{11}$. Raffinose has no reducing properties, and therefore forms no osazone. Nitric acid oxidises it to oxalic, saccharic, and mucic acids. It forms an endeca-nitrate and an endeca-acetate. Like cane sugar it unites with calcium, barium, and strontium oxides. It is not inverted by diastase; but it is inverted to lævulose and melibiose by invertase; and another yeast enzyme (meliboglycase) inverts the melibiose. Zymase slowly, but completely, ferments it. Raffinose occurs in eucalyptus-manna, in cotton seeds, and in beetroot sugar molasses. It can be obtained from the manna by repeatedly extracting it with boiling water and some animal charcoal and purifying the product by recrystallisation from dilute alcohol.

Rafters (*Build.*) The timbers to which the roof covering is fixed. *See* ROOFS.

Rag. (1) The name given to various kinds of stone found in different parts of England, and used for building purposes; *e.g.* Kentish rag. *See* BUILDING STONES. (2) A large roofing slate with one side rough.

Rag Bolt (*Build.*) (1) A bolt with an enlarged end for bedding in masonry. (2) A bolt with barbs or jags in the direction of the head, so that it cannot be withdrawn after being driven in.

Rag Grinding (*Mango or Shoddy Manufac.*) The operation of reducing rags made of wool, worsted, or mixed materials to fibre. Done by a rag grinding machine.

Raglet (*Build.*) A groove cut in a wall, into which the edge of flashing (*q.v.*) is turned.

Raguly *or* **Ragulée** (*Her.*) Having projections. A dividing line similar to "embattled," but with the projections slanting. *See under* HERALDRY.

Rail (*Carp.*) A general term for a horizontal member in a framed structure.

—— (*Eng.*) Applied in a general sense to a long bar, especially to a bar along which the wheels of a vehicle run. Rails are described according to the kind of line for which they are used, and are further distinguished according to cross section as Double Headed Rails, etc. *See under* RAILWAYS.

Rail Bender (*Eng.*) A massive clamp used for bending rails to an arc of a curve. The force necessary to bend the rail is applied by a screw or by hydraulic pressure.

Rail Bond (*Elect. Eng.*) An electrical connection established by means of conductors, usually of copper, between the adjacent ends of two lengths of rail in electric traction.

Rail Clamp (*Eng.*) A clamp or bracket used to hold a ratchet drill (*q.v.*) in place when a rail is being drilled; by this means a hole can be made in a rail while it is in position.

Rail Fagot (*Eng.*) A FAGOT or pile (*q.v.*) of bars of different qualities of iron, which is to be used for rolling rails. Fagoted iron rails are now almost superseded by steel rails.

Rail Gauge (*Eng.*) A measuring bar used in fixing rails the proper distance apart.

Rail Guards (*Eng.*) Bars fitted to the front of the frame of a locomotive, and reaching nearly down to the rails. Their purpose is to remove obstacles from the surface of the rails.

Rail Ingots (*Eng.*) Ingots of Bessemer steel about 1 ft. square, from which steel rails are rolled.

Rail Tests (*Eng.*) Rails are usually tested by allowing a heavy mass of specified weight to fall on a rail resting on two supports. The amount of deflection is noted, and from this, in conjunction with chemical tests, the quality of the rail can be estimated.

Railways. Early in the seventeenth century an inventive genius, with a view to reduce frictional resistance on roads, hit upon the idea of laying down parallel blocks of timber for the wheels of vehicles to travel on, thus forming a TRAMROAD, in the neighbourhood of coal and iron mines. No marked strides seem to have taken place until about a century later, when the wooden blocks were abandoned in favour of cast iron plates, which were secured to iron shoes bolted to stone blocks. Vehicles drawn by horses, and fitted with flanged wheels, travelled on these plates; but this road proved much too rigid, and eventually the stone blocks were replaced by timber sleepers, and the cast iron plates by wrought iron rails. The application of STEAM as a motive power was assuming practical lines early in the nineteenth century, leading to further improvements and developments of the tramroad, which was now merging into the dignity of a railroad. In 1821 a line was opened for goods traffic between Stockton and Darlington, followed in 1830 by the first railway designed for passenger traffic, *viz.* from Liverpool to Manchester, engineered by the famous George Stephenson. The line was a double one, and the motive power the historical engine "Rocket," made by Stephenson. This enterprise proved an immediate financial success, resulting in an enormous development in the construction of railways, the movement quickly spreading to the Continent and America and gradually to every part of the globe. It is scarcely possible to realise the full importance of the introduction and extension of railways as a factor in the world's progress and advancement.

Approximately, the present MILEAGE (1905) is 534,300, distributed as follows:

	Miles.
Europe	186,720
Asia	46,530
Africa	15,560
N. America	239,020
S. America	29,860
Australia	16,610
Total	534,300

The capital involved is nearly £8,000,000,000 (eight thousand millions). In the United Kingdom the mileage is 22,435, the capital £1,245,629,000, and the approximate number of people employed 500,000. In this country the construction of railways is controlled by various Acts of Parliament, and before a new line can be opened for passenger traffic the Board of Trade must certify that it has been properly constructed and equipped and all rules and regulations complied with.

CONSTRUCTION.—In laying out a railway the cuttings should as far as possible balance the embankments, consistent with workable curves and gradients. On the earlier railways gradients were seldom constructed steeper than 1 in 200, nor curves sharper than 60 chains' radius; but with the improvements in the permanent way and engines and the introduction of machine brakes, gradients of 1 in 50 and curves of 15 chains' radius became common. These limits are greatly exceeded on mountain railways, where gradients of 1 in 4 and curves of about 300 ft. radius are frequent, such steep gradients being workable by the "Abt" or the "Fell" System, or some form of rack and pinion, and the provision

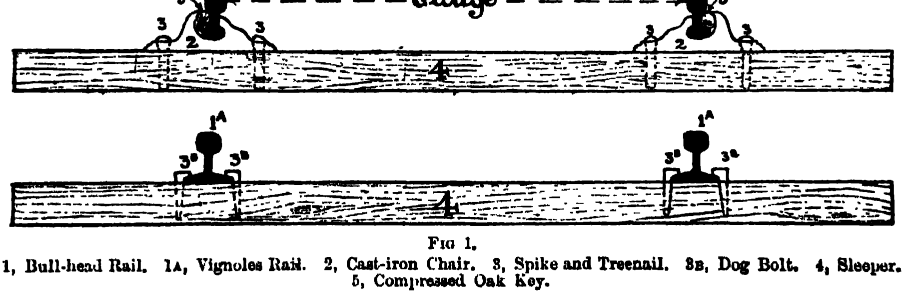

FIG 1.
1, Bull-head Rail. 1A, Vignoles Rail. 2, Cast-iron Chair. 3, Spike and Treenail. 3B, Dog Bolt. 4, Sleeper. 5, Compressed Oak Key.

of powerful machine and automatic brakes. The FORMATION is the prepared surface in cutting or embankment ready to receive the ballast and permanent way. The slopes or batter of the sides of the cuttings and embankments vary with the geological formation passed through. For ordinary soil the most usual is a batter of 1½ horizontal to 1 vertical, but in some kinds of clay the slopes may reach 3 or 4 to 1, whilst a cutting in rock may have vertical sides. The width of formation for a single line is 18 ft. and for a double line 30 ft. A layer of broken stone or coarse gravel 12 in. deep is first placed on the formation, upon which rests the PERMANENT WAY. The modern practice is to place sleepers 9 ft. long × 10 in. × 5 in., generally creosoted (*see* CREOSOTE) about 2 ft. 6 in. apart. Cast iron chairs weighing from 30 to 50 lb. are fastened to these sleepers by spikes and treenails, through-bolts or coach screws, and the RAILS are placed in these chairs and secured by compressed oak keys. *See* fig. 1. In Great Britain the form of rail favoured is the Bullhead, varying in weight from 65 to 100 lb. per lineal yard. Following the American practice of STANDARDISING, which has resulted in many advantages, a committee (Engineering standards) of experts consisting of well known English engineers and others, have recently decided upon a standard rail, both as regards manufacture and dimensions. *See* Fig. 2, which gives three of the standard sections. In future the rails used in this country will comply with the suggestions of the committee. They will be manufactured of steel made by the Bessemer or Siemens-Martin process and to the following limits in chemical composition, *viz.*:

Carbon	0·35 to 0·5 per cent.
Manganese . . .	·7 to 1·0 „ „
Silicon not to exceed .	0·1 „ „
Phosphorus . . .	0·075 „ „
Sulphur	0·08 „ „

On the Continent and America the type of rail mostly used is the Vignoles or Flat Bottom (fig. 1). Chairs are not necessary with these rails; they rest either directly on the sleepers, or sometimes a sole plate of thin wrought iron is placed between the rail and sleeper to prevent the rail squeezing into the latter. Rails are usually 30 ft. in length, although 45 ft. is a dimension now becoming general on important lines. The joints are secured by a pair of plates (Fishplates) from 1 ft. 6 in. to 2 ft. in length, with four bolts from ⅞ in. to 1 in. diameter, provision being made for expansion and contraction by slotted holes in the rails. In countries where timber is scarce, or where it is attacked by ants (*e.g.* India) sleepers made of wrought or cast iron are used. The ORDINARY GAUGE in Europe and America is 4 ft. 8½ in. In Ireland it is 5 ft. 3 in., and India 5 ft. 6 in. NARROW GAUGE varies from 1 ft. 6 in. to 3 ft. 6 in., a very large mileage being on the metre gauge (3 ft. 3⅜ in.) The JUNCTION of one line of rails with another is effected by means of switches or points (fig. 3). These are tapering movable rails. The intersection of one rail with another is termed a CROSSING. In America it is termed a FROG (fig. 3). To insure the safe movement of trains, SIGNALS and signal boxes are provided at stations, and also at intervals between them. The signals are usually worked by manual labour by means of levers, and are so arranged that it is not possible to lower a signal for the passage of a train unless the points are properly set, locked in position, and all conflicting signals at "danger." This is termed "interlocking." *See* fig. 4. At present

power signalling is coming into favour, the power being either compressed air or electricity, in lieu of manual labour. A further development is the automatic signalling. Briefly described, this system is as follows (fig. 5): The line is divided into sections of about one mile, and the rails at these points are insulated by means of a special block joint. Every such length forms a distinct section from block to block with the signals controlling it, the intervening joints as to ensure the distant signal remaining at the "on" or danger position until the home signal on the next forward post has returned to the "off" or alright position after the train has passed out of the next adjoining section. Fig. 5 shows a diagram of one section of a line with an automatic pneumatic signalling installation. Doubtless automatic signalling will be extensively adopted in the near future on main lines. It not only increases the carrying

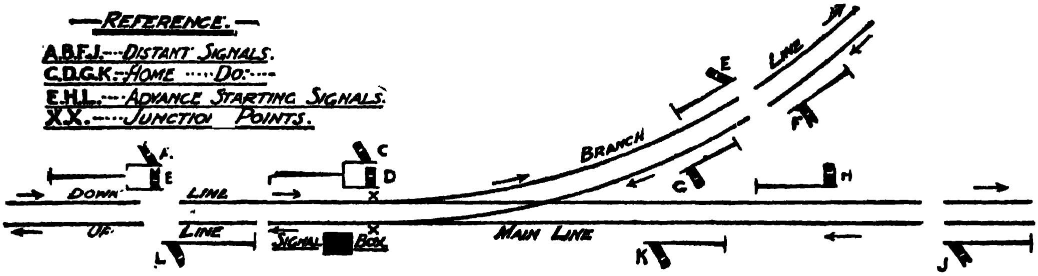

Fig. 4.—Signals.

The road is set for a down branch and up main train; and before Signals A C E J K and L can be lowered, the Points at X X must be locked over in position, and all conflicting Signals must be at the danger position as shown.

being bonded (*i.e.* electrically connected) by means of copper or other suitable wire. The semaphore signals are placed in proximity to the bonded joints, and are moved by levers actuated by compressed air, controlled by valves. The latter are operated by electro-magnets, working with relays (*q.v.*) on the rail or track circuit. A track battery is connected in circuit with the rails, and placed at the end farthest from the signals; a low voltage current is transmitted through one rail to a relay against the signal and through this relay back to the battery along the other rail. A signal battery having a circuit through the contact joint on the track relay, capacity of the line, but tends to greater safety in working.

In no detail has greater strides been made than the Locomotive. From a machine weighing 4½ tons, working at a steam pressure of about 50 lb. and capable of hauling some 20 tons, we now have engines exceeding 100 tons, with a weight of 20 tons on the driving axle, working at a pressure of about 240 lb. per square inch, and capable of hauling 500 tons and upwards. In America goods trains weighing as much as 3,000 tons are not uncommon. To facilitate the working of traffic at goods stations numerous mechanical devices are used, such as steam,

operates an electro-pneumatic valve by means of the electro-magnet. Assuming there is no train on the line, the signals stand at the "alright" or "off" position by reason of the air pressure in a cylinder actuating the semaphore. This compressed air is generated at a central generating station, and conveyed along the railway by means of a small iron main. When a train enters a section the track circuit is broken down by the wheels and axle forming a short circuit; the relay is now de-energised. This has the effect of closing the valve supplying the air, and the semaphore goes to the "danger" or "on" position by gravity. Circuit breakers are so arranged hydraulic, and electric cranes, hydraulic capstans, turntables, and hoists.

Brakes.—The block system in connection with the working of railways is compulsory in this country, as is also the use of automatic continuous brakes on passenger trains. There are several such brakes, but only two in general use, *viz.* the Westinghouse Automatic and the Automatic Vacuum. Shortly described, the former is worked by compressed air obtained from a small compressor fixed on the engine, which compresses air to about 80 or 100 lb. per square inch. Fig. 6 gives a diagram of the working of the brake. The compressed air is stored in a main reservoir

fixed under the engine, and from this it is conveyed by a main pipe the whole length of a train. Branch pipes connecting with a triple valve, subsidiary reservoir, and brake cylinder are fixed under each vehicle, and two brake blocks are usually placed against each wheel. The brake cylinders are provided with a pair of pistons held together by spiral springs, and under normal conditions the main pipe and reservoirs are charged with compressed air which is shut off from the brake cylinders by means of the triple valve, and equilibrium is maintained. To apply the brakes the driver or guard opens a valve which reduces the pressure in the main pipe, opening

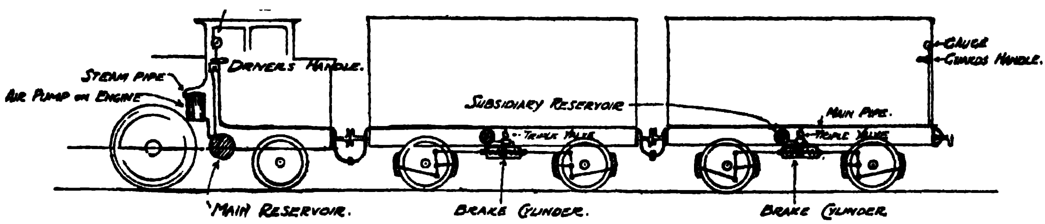

Fig. 6.—Westinghouse Automatic Brake.

the top port in the triple valves and causing the air in the subsidiary reservoirs to enter the brake cylinders between the two pistons, forcing them asunder, and actuating the brake blocks by rods and levers. A similar operation takes place automatically should a vehicle become detached accidentally, as the main pipe is thereby severed. By opening a valve between the main reservoir and main pipe the pressure is restored, the brake blocks return to their normal position and equilibrium again obtains. The action of this brake is very rapid; trains travelling at great speed can be pulled up in little more than their own length. Fig. 7 shows diagrammatically the working of the Automatic Vacuum Brake. This consists

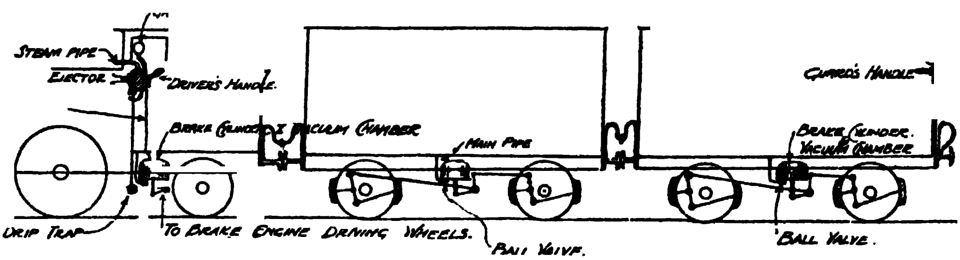

Fig. 7.—The Vacuum Automatic Brake.

of an ejector placed on the engine connecting with brake cylinders and vacuum chambers, fixed under each vehicle by a main pipe which extends the whole length of the train, terminating in the guard's van. The brake cylinders are fitted with a piston connected with brake blocks on each wheel by means of rods and levers in a manner somewhat similar to the last described brake. Before starting a journey the driver operates the ejector which creates a vacuum in the main pipe and brake cylinders, equilibrium then obtains, and the brake blocks hang free. To apply the brakes the driver or guard opens a valve admitting air at atmospheric pressure into the main pipe, which enters the brake cylinders and forces the piston upwards: this in turn actuates the brake blocks. To restore equilibrium and remove the brake blocks the ejector is again brought into action and a vacuum created. In the event of the main pipe becoming severed accidentally, air is admitted and the brakes are automatically applied. This brake is also very rapid in action and is largely used.

Electricity as a motive power is now being much favoured by railway companies, the advantages claimed being that it enables a greater volume of traffic to be dealt with at a reduced cost of working. Several existing railways are electrifying their systems, a notable instance being the underground lines of London. In America electric railways have already reached a considerable mileage, and there is little doubt the development of this system of motive power is likely to be far reaching.

A Light Railway is a railway made under powers obtained from the Board of Trade and the Light Railway Act, the object being to develop country districts at present not provided with railways. Such lines are constructed as cheaply as possible, level crossings are allowed in lieu of bridges, and signalling is as simple as is consistent with safety.—A. W. S.

Railway Wheels. Although the wheels and axles used on railways vary in detail, the general types do not differ greatly. There is, however, a marked difference between the wheels of a roadway and a railway vehicle; *i.e.* in the case of the former the wheels revolve on the axle, whereas on the latter the wheel and axle revolve together. There are two general types of railway wheels in use in Great Britain, *viz.* the open body with spokes or arms now used chiefly for wagons, and the solid body or Mansell wheel fitted to carriages and vans. A wheel consists of the axle, terminating in journals (which accommodate the axle-box, brasses, springs, etc.), boss, body, tread, and tyre, the two latter together constituting the flange. The axles are made of a high class wrought iron or steel, capable of being bent double, when cold, without fracture; the boss may be of cast or wrought iron, and is shrunk on the axle; the body may be of wrought iron or solid

wood; the flange is of steel. When the body is of wrought iron the spokes or arms are fixed in the hub, and secured to the flange by shrinking and keying (fig. 1). In a Mansell wheel the solid

5. Tread. } Flange.
6. Tyre.

wooden body is bolted to the hub and flange, as shown in fig. 2. The advantages of a Mansell wheel are the reduction in resistance and a continuous support to the flange. In America and other countries a wheel made of cast iron is favoured. A system now largely adopted is the bogie truck, which consists of two or three pairs of Mansell wheels attached to a frame. The carriage rests on two such bogie trucks, one at each end, and is fixed by a pivot placed in the centre of each truck. This arrangement greatly reduces the rigidity of the wheel base, and enables the vehicle to travel round sharp curves with the minimum of friction.

Rain (*Meteorol.*) When clouds form over a region in which the air is nearly or quite saturated with moisture, the globules of water which form the cloud unite and descend through the stratum of moist air underneath, and fall as rain when the temperature is above freezing point. *See* CLOUDS *and* SALT.

——, **Geological Action of.** Rain water contains a small percentage of carbonic acid, which enables it to act chemically upon various rocks, especially upon limestone. But its chief function consists in washing away disintegrated materials, and thus exposing new surfaces to attack. Furthermore, rain contains a small percentage of the salt dust derived from sea spray, which is transferred from the air to the land. These salts may be carried by streams to arid regions, and there accumulate as the water evaporates.

Rain Band (*Meteorol.*) An absorption band in the solar spectrum due to the aqueous vapour in the earth's atmosphere. The intensity of this band increases as the aqueous vapour becomes more abundant.

Rainbow (*Meteorol., Phys.*) The prismatic arch of light formed by the reflection of light from the internal surface of drops of rain on which the sun is shining. The chief or PRIMARY BOW has a radius of 40° for the violet and 42° for the red light; hence the violet is inside, the red outside. The SECONDARY BOW is due to light which has been reflected twice; it is outside the primary bow, and the relative position of the colours is reversed. The radii are 51° for the red and 54° for the violet light. Bows due to three, four, etc., reflections are occasionally produced; they lie between the observer and the sun, but are obscured by the bright light. The fifth bow, however, is occasionally observed, as it lies in the same part of the sky as the primary and secondary bows. LUNAR BOWS, which are similar phenomena produced by the moon, are occasionally noticed under favourable conditions at full moon. Inside the primary or just outside the secondary bows there may sometimes be seen other bows; these are termed COMPLEMENTARY, SPURIOUS, or SUPERNUMERARY BOWS; they are due to INTERFERENCE (*q.v.*)

Rain Cloud (*Meteorol.*) A cloud or system of clouds from which rain is falling. This type of cloud is the Nimbus or Cumulo-cirro-stratus. *See* CLOUDS.

Rainfall (*Meteorol.*) The amount of rain falling in a given time is expressed by the depth to which it would cover a flat surface if the whole of the water remained upon it. "One inch of rain" is an amount which would cover the ground to a depth of one inch; this requires about 60,000 tons of water per square mile. *See also* METEOROLOGY.

Rain Gauge (*Meteorol.*) An instrument which in its simplest form consists of a funnel whose opening or mouth is of known area, and a collecting vessel, screened from wind and sun to prevent evaporation, placed beneath it. By measuring the total quantity of rain collected in a given time, it is easy to calculate the amount which has fallen on any area.

Rain Water (*Chem.*) *See* WATER.

Rain Water Pipe (*Build.*) The pipe that carries the water from the roof, gutters, etc.

Rain Water Separator, Roberts'. An apparatus which prevents the suspended matters—soot, decaying leaves, bird droppings—in rain water from passing into the storage tank. The separator is made of zinc upon an iron frame, the centre part being placed on a pivot. The first part of the rainfall passes through a waste pipe, and after a certain amount has fallen the separator cants over and passes the clear water into the storage tank.

Raised Beach (*Geol.*) Strictly speaking, the term "raised beach" ought to be restricted to deposits of sand and shingle which have been formed at the margin of a lake or on a seashore by the action of the waves, and have subsequently been elevated by terrestrial movements to a position in which, while the level character of the surface is still retained, the waves can no longer affect the deposit. But the term is also applied to a rocky shelf or ledge which has been sculptured by wave action, and has been elevated so as to be out of reach of the agent that shaped it.

Raised Oil. *See* RAISING.

Raised Panel (*Carp. and Join.*) A panel thicker in the centre than at the edges.

Raised Work (*Eng.*) Sheet metal work which has been shaped by hammering. This process is chiefly used in the production of ornamental work in copper, brass, etc.

Raising (*Leather Manufac.*) A process of raising or recovering the oil from the washings in the manufacture of chamois or oil leather. The wash waters are run into a large tub and heated with acid. The acid splits up the soap, and the oil is "raised" and floats on the surface: this oil is termed "RAISED OIL" or "SOD OIL" (*q.v.*)

—— (*Woollen Manufac.*) Applied to woollen cloths, and consists of drawing the fibre from the surface of the threads by means of teazles or card wire. Such cloths as beavers, meltons, pilots, blankets, etc., are raised

Raising Piece (*Carp.*) A timber laid on a wall or other support to carry a beam or beams.

Raising Plate (*Carp.*) A wall plate for carrying the heels of rafters. *See* ROOFS.

Rake (*Mining*). A Cornish term for a lode or vein.

——, **Raking.** (1) Slope or inclination. (2) A tool of the familiar pattern, used in many metallurgical and other operations.

Raking Bond (*Build.*) Diagonal or herring-bone bond.

Raking Cornice (*Architect.*) The cornice in a pediment (*q.v.*) bounding the sloping sides of the tympanum (*q.v.*)

Raking Flashing (*Build.*) The inclined flashing (*q.v.*) used on a roof against a stone wall.

Rallentando (*Music*). Gradually decreasing the pace.

Ram (*Eng.*) The piston of a hydraulic press (*q.v.*)

Ramie Fibre (*Botany*). A fibrous material which is now often used for many purposes in which cotton was formerly employed. *See* RHEA.

Ram Leather (*Eng.*) The cup leather of a press. *See* HYDRAULIC PRESS.

Rammer (*Foundry*). A cast iron head fixed to a handle; used for filling a moulding box and forcing the sand into close contact with the pattern.

Ramp (*Build.*) (1) A curve, concave on the upper surface; *e.g.* the upward bend of a handrail at a landing. (2) The curved or straight shoulder connecting the coping of a wall at different levels. (3) The coping of a stair or steps. (4) The difference of level in the abutments of a Rampant Arch (*q.v.*)

—— (*Eng.*) An inclined plane used in raising or lowering heavy weights through small distances.

Rampant (*Her.*) Lions and beasts when represented standing on the hind legs with one fore leg elevated are blazoned rampant. It is the natural position of an animal springing on its prey.

Rampant Arch (*Build.*) An arch with its springing higher on one abutment than the other.

Rampant Guardant (*Her.*) As rampant, but face turned to spectator.

Rampant Reguardant (*Her.*) As rampant, but head turned to look behind.

Random (*Typog.*) A sloping frame, generally used in making up type into pages.

Random Ranges (*Textile Manufac.*) Experimental ranges or pattern trials made with a view of acquiring styles from which ranges proper may be constructed.

Random Rubble (*Build.*) Masonry consisting of stones of various sizes and shapes which are not built in courses.

Range. (1) Compass, extent, scope. (2) A series of things standing in line. (3) The series of sounds of which the voice or a musical instrument is capable. (4) A kitchen grate with which is combined a cooking apparatus, etc.

—— (*Biol.*) (1) The geographical distribution of an animal or plant. (2) The geological period throughout which it has existed on the earth.

Ranging *or* **Setting Out** (*Surveying*). The location and marking on the ground of required points.

Ranging Rod (*Surveying*). A simple straight rod, coloured so as to be easily distinguishable, used for marking any required point.

Rank (*Music*). Used of pipes in an organ, and signifies a row of pipes belonging to a certain stop. The mixtures are of three, four, or five ranks. *See* MIXTURES.

Ranseur (*Arms*). A mediæval spear with accessory spikes at the base of the point.

Ranunculaceæ (*Botany*). An important natural order of Dicotyledons, chiefly found in the North Temperate Zone. Many garden and medicinal plants belong to the order, such as Aconitum, Actæa, Clematis, Ranunculus, Delphinium, Pæonia.

Raoult's Method (*Chem.*) A method of determining molecular weight by the lowering of the freezing point of a solution. The apparatus commonly employed is Beckmann's. It is described under FREEZING POINT (*q.v.*)

Rape Oil. This oil is substantially the same as colza oil, and is prepared by expressing the small black spherical seeds of the rape plant, *Brassica napus*, which is grown in most parts of Europe and in many places abroad. The oil is used for illuminating, in soapmaking, and for lubricating purposes. Sp. gr. at 18° C. 0·914 to 0·916.

Raphides (*Botany*). The term applied to the needlelike crystals of oxalate of lime, usually acicular in form, found in the tissues of many plants.

Rapidamente, Rapido (*Music*). With rapidity.

Rapier (*Arms*). A light, narrow, sharp pointed sword (a small sword), designed for thrusting, used from the sixteenth century onwards. Originally a long two edged sword, suited for cutting or thrusting.

Rapping (*Foundry*). Loosening a pattern from the sand by tapping or hammering. To prevent injury to the pattern, plates of metal termed RAPPING PLATES are let into the wood in convenient positions; these may be struck with suitable tools termed RAPPING BARS and RAPPING MALLETS.

Rasch (*Music*). Quick; comparative, *rascher*.

Raschette Furnace (*Met.*) A form of BLAST FURNACE (*see* FURNACES) with a wide hearth and a number of tuyères; it is used in smelting lead and copper in America.

Rasp (*Carp., etc.*) *See* FILES.

Raspberry (*Botany*). A well known fruit, *Rubus idæus* (order, *Rosaceæ*), consisting of an aggregate of drupes. Each small drupe has a similar structure to that of a cherry or plum.

Ratchet. A RATCHET WHEEL (*q.v.*)

Ratchet Bar (*Eng.*) A bar with teeth like those of a RATCHET WHEEL (*q.v.*)

Ratchet Brace (*Eng.*) A tool for drilling holes in confined situations: the drill is rotated by a ratchet actuated by the handle of the brace, and pressure is applied to the tool by means of a screw which works in a nut on the brace itself or in a separate frame or clamp; turning this screw causes the "feed" or motion of the drill in the direction of its own length.

Ratchet Drill (*Eng., etc.*) *See* RATCHET BRACE.

Ratchet Wheel (*Eng., etc.*) A wheel with teeth of peculiar shape, somewhat resembling those of a circular saw. These teeth engage with a PAWL, a piece of metal hinged at one end and coming in contact with the edge of the teeth at the other. The paul may serve the purpose of communicating motion to the wheel or of preventing it from turning backward (*i.e.* it allows motion in one direction only).

Ratching (*Cotton Spinning*). The excess speed traverse of a mule carriage over the roller delivery as it travels outwards. This has the effect of stretching and subjecting the twisted thread to a further draft, and produces a more even spun thread. Sometimes spoken of as "Carriage gain."

Rate of a Chronometer (*Astron.*) The amount it gains or loses during one day. Rate is reckoned positive when the clock loses.

Rate of Denudation (*Geol.*) *See* DENUDATION, RATE OF.

Ratio (*Math.*) The relation between two magnitudes or quantities of the same kind; it is expressed by stating what multiple, part, or parts, one quantity is of the other. In mathematical symbols the ratio of A to B may be written A : B or $\frac{A}{B}$

Rational Formula (*Chem.*) Is the same as constitutional formula. *See* CHEMICAL FORMULA.

Ratio of Expansion (*Eng.*) The relation of the final volume to the initial volume of a gas which is allowed to expand. The term is especially applied in engineering to the expansion of steam in the cylinder of an engine.

Ratio of Specific Heats (*Phys.*) *See* SPECIFIC HEATS OF GASES.

Rat Trap Pedals (*Cycles*). Pedals in which the foot rests on notched steel bars instead of on bars covered with rubber. Lighter than the latter form, but not so free from vibration.

Raw. A term applied to various substances to denote that they are in a natural, unrefined, unmanufactured, undiluted, or undressed condition; *e.g.* raw hide = untanned hide; raw silk, silk simply reeled from the cocoon.

Raw Hide. Leather which has not been tanned. It is sometimes used for thongs and for driving belts.

Raw Linseed Oil. Oil that has not been boiled, so called to distinguish it from boiled linseed oil. *See* OILS.

Ray (*Music*). Second degree of scale in "Movab'e Doh" system.

—— (*Phys.*) The line along which the disturbance produced in any form of wave motion travels. Thus a ray of light may be regarded either as a line along which light travels, or as a normal to the wave front (*q.v.*)

Rayonné (*Her.*) *See* RADIANT.

Rays (*Her.*) The sun as a charge is sometimes represented with rays; they are alternately straight and wavy, and sixteen in number.

Rb (*Chem.*) The symbol for RUBIDIUM (*q.v.*)

Re (*Music*). The sol-fa syllable for D.

Reactance (*Elect.*) That part of the impedance (*q.v.*) of a circuit which is due to its self induction and capacity. In most cases in practice the effect of capacity can be neglected, and the reactance is $2\pi nL$, where L is the self induction and n is the frequency. *Cf.* IMPEDANCE.

Reactance Coil (*Elect. Eng.*) A CHOKING COIL (*q.v.*)

Reaction (*Chem.*) Chemical action occurring between two or more substances.

—— (*Mech.*) A general term for a force which is acting in opposition to another force or system of forces.

Reader (*Typog.*) A person whose province is to correct errors of the compositor in setting type, revise the various proofs, and be responsible for the accuracy of the forme before it is finally printed off. His duties commence with the first proof or impression, which is "run through" with the copy by its side, and all literals and other obvious errors marked by means of special signs. *See* PROOF CORRECTIONS. The copy is then given to a boy or girl, usually called a copyholder, who reads it aloud while the reader verifies the proof, paying special regard to orthography, punctuation, division and compounding of words, use of capitals, and the general "style" of the house, etc. When all the necessary marks are made, the proof is handed to the compositor, who corrects it and pulls a "revise." The reader compares this with the first proof to see that all his marks have been carefully followed, in which case the type is made up into pages and imposed, etc. A proof in sheet form is pulled and folded, but not cut. It is then the reader's duty to read the headings of the pages, check the size, style, and register of the make up, and verify the folios or pagination, signatures, and connections of the pages. When these points have had due attention by the compositor, the author's proof is pulled; and after the reader has indicated upon it any query he deems necessary to raise, it is submitted for approval. On its return, this proof is carefully and critically perused by the press reader as a whole. In the event of the alterations being considerable, involving disturbance of lines or paragraphs, the proof is first given to the compositor; and after the author's corrections are made, a further proof or press revise is pulled, upon which the final marks are made, and the work "passed for press."

Readers' Marks (*Typog.*) *See* PROOF CORRECTIONS.

Reading Beds (*Geol.*) A series of clays, loam, and sands, with some pebble beds, formed under fresh water, estuarine, and marine conditions during the Lower Eocene Period in the London Basin. The estuarine and marine type is found to the east of London, and the fresh water type mostly to the south and the west.

Reading Microscope *or* **Telescope** (*Phys., etc.*) A microscope or telescope used for reading the indications of a finely divided scale or other instru-

ment, or for measuring small distances. Reading microscopes are usually mounted so that the axis of the instrument can be moved parallel to itself through small distances, which can be accurately read off on a scale attached to the frame of the instrument. In many cases a fine adjustment is provided by means of a screw with a graduated head.

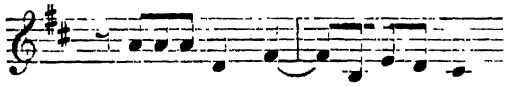
Reading Off (*Lace Manufac.*) Converting the lines that represent threads upon the draft into figures for the use of the Jacquard card puncher. *See* DRAFTING.

Reagent (*Chem.*) Any chemical substance (element or compound) used to bring about a chemical change. Thus in qualitative analysis (*q.v.*) the chemicals used to precipitate the various groups of metals are called group reagents. The word is, in fact, more commonly used to denote chemicals used in testing than any others. For example, we have the alkaloid reagents (*q.v.*), Nessler's reagent (*q.v.*) Phenylhydrazine is a reagent for aldehydes and ketones.

Real Fugue (*Music*). A fugue having the intervals of the answer strictly repeated in the fifth above (or fourth below), *e.g.*:

Subject. J. S. BACH.

Real Answer.



Realgar (*Min.*) One of the sulphides of Arsenic; AsS. Arsenic = 70·1, sulphur = 29·9 per cent. Monosymmetric, usually massive. Colour, orange red; lustre, resinous. It is usually associated with the other sulphide Orpiment. From Northern Hungary, Transylvania, Bohemia, Asia Minor, etc.

Real Image (*Light.*) *See* IMAGE *and* CONJUGATE FOCI.

Realism (*Art, etc.*) Rendering or reproducing precise details of a subject or scene. In recent years the term has been employed to indicate that the details are of an unpleasant character. Opposed to Idealism.

Ream (*Paper Trade*). A certain quantity of paper, generally 480 sheets or 20 quires, but varying slightly according to the purpose for which it is intended; *e.g.* a printers' ream consists of 21½ quires (516 sheets), to allow for waste in printing.

Reamer (*Eng., etc.*) A tool used for enlarging or truing a hole already drilled. A common form consists of a short shaft with longitudinal cutting ridges.

Rear Vault (*Architect.*) The vaulted surface on the interior of a window head in a thick wall.

Rebate (*Carp., etc.*) A synonym for RABBET (*q.v.*)

Rebated (*Her.*) Broken off.

Rebec (*Archæol.*) A lute-shaped musical instrument of mediæval times, with one, two, or three strings, played by a bow; the prototype of the violin.

Rebus (*Her.*) An allusive device. Charges frequently occur in heraldry in which the bearer's name is suggested. For instance, Dearing blazons a deer and a ring; Ashton, an ash tree issuing from a tun or cask; Abbot Ramryge adopted for supporters two rams wearing collars with the letters "Ryge."

Recalescence (*Phys.*) If a piece of iron wire which has been heated to a red heat be allowed to cool in a dark room, it cools down, losing its glowing appearance, and then suddenly glows out again, when its temperature has fallen to a certain value. This phenomenon is termed RECALESCENCE, and the temperature at which it occurs the TEMPERATURE OF RECALESCENCE.

Receiver (*Eng., etc.*) (1) A general term for a receptacle, place of storage, etc. (2) In the foundry, a tank into which metal for large castings is run from the cupola, and from which it is run into the moulds. (3) In telegraph and telephone practice, etc., it signifies the instrument by which a message is received.

Recess (*Build.*) The inside of a REVEAL (*q.v.*)

Recessing Machine (*Join.*) A machine used for sinking (*q.v.*), housing (*q.v.*), and for cutting out recessed and shaped work generally.

Reciprocal. The reciprocal of a quantity is equal to unity divided by the quantity.

Reciprocal Figure. *See* GRAPHIC STATICS.

Reciprocating. Applied in engineering, etc., to mechanism of which the parts move backwards and forwards alternately, as is the case in ordinary steam engines.

Recitando, Recitante (*Music*). In a reciting manner.

Recitative (*Music*). A composition without regular rhythm, being of a declamatory character. Recitatives are of two kinds: (1) *Recitativo secco*, recitative supported by occasional chords only, in which the performance is in free time; and (2) *recitativo con accompagnamento* or *stromentato*, accompanied recitative, in which the performance is in comparatively strict time. "Comfort ye My people" (Handel's *Messiah*) is a good example of both kinds of recitative.

Recorder. An instrument which produces a record of its indications in some form of written or printed symbols. *See also* RECORDING AMMETER, *etc.*

Recording Ammeter, Voltmeter, etc. (*Elect.*) An instrument by which the value of a current, voltage, etc., is continuously recorded on a drum or card.

Recording Drum (*Phys., etc.*) A revolving drum covered with paper or some other suitable surface, on which the indications of an instrument are recorded by means of a line whose distance from a fixed zero line represents the displacement of the indicating portion of the instrument, and therefore the value at any given instant of some quantity which it is desired to record. The drum is rotated at a known uniform rate by clockwork or other means.

Recovered Sulphur (*Chem.*) *See* CHANCE'S PROCESS.

Rectangle. A plane, four-sided figure, whose angles are all right angles.

Rectangular Components. *See* RESOLUTION OF FORCES.

Recte et Retro, Per (*Music*). *See* PER RECTE ET RETRO.

Rectification (*Chem.*) Literally a second distillation. To rectify a liquid means to redistil it. Rectified spirit is alcohol which has been at least twice distilled; it has a variable strength of from over 80 to about 91 per cent. by weight of alcohol.

—— (*Elect.*) The conversion of an alternating current into a continuous or uni-directional current.

Rectified Spirit. *See* ALCOHOL.

Rectifier (*Elect. Eng.*) A machine or piece of apparatus for converting an alternating current into a uni-directional current. A rectifier may be (1) a mechanical device of the nature of a COMMUTATOR (*q.v.*), or (2) a ROTARY CONVERTER (*q.v.*), or (3) it may depend on some electrolytic action, being then termed a CHEMICAL *or* ELECTROLYTIC RECTIFIER. Electrodes formed by a pair of plates of aluminium, dipping into a suitable solution (*e.g.* ammonium phosphate) are connected to the alternating current supply, when it is found that the current will pass through the cell in one direction only. The current may be used for actuating an induction coil or even for charging accumulators.

Rectilinear (*Architect.*) *See* CURVILINEAR *and* PERPENDICULAR.

Recto (*Typog.*) The right hand page of a printed work. *Cf.* VERSO.

Rectum (*Zoology*). The terminal portion of the alimentary canal communicating with the exterior by the anus.

Red Builders. *See* BRICKS.

Red Crag (*Geol.*) A member of the Older Pleiocene Rocks which is typically developed in East Anglia. It contains a large number of species and individuals of fossil shells in a good state of preservation. The formation, as a whole, presents a ruddy aspect, which is due to the presence of iron oxide, probably arising from the alteration of Glauconite.

Reddle (*Eng.*) A mixture of red lead and oil, used to show which parts of two surfaces are in contact when brought together as closely as possible. The mixture is rubbed on one surface, and it marks the points of contact when the second surface is pressed or rubbed against the first. *See* SURFACING.

—— (*Min.*) An earthy variety of Hæmatite (*q.v.*), used as a pigment and as a polishing agent. *See* HÆMATITE.

Red Fog (*Photo.*) A reddish haze on a negative. Red fog is very apt to make its appearance during intensifying with silver nitrate if the solution is not kept in motion, or if too little acid is present as a restrainer.

Red Heat. The temperature at which a body emits a red glow. It varies within certain limits, but may be given as 700° to 800° C.

Red Lead (*Chem.*) *See* LEAD COMPOUNDS.

—— *or* **Minium** (*Dec.*) An oxide of lead having an approximate formula of Pb_3O_4 and a specific gravity of about 8·62. It is of a bright orange or scarlet colour, and is made from metallic lead, which is heated in an open furnace, a current of air being passed over the molten lead, which absorbs oxygen, and is converted into litharge. This is ground to a fine powder, and heated in the furnace a second time, when it absorbs more oxygen, and becomes (when cool) a bright red colour. The principal advantages of red lead have been thus summarised: It is inexpensive; it forms a strong protective covering to the iron or woodwork to which it is applied; it is very durable, resisting alike the action of frost, damp, and heat; it is remarkably adhesive; it mixes well with linseed oil; it has a powerful drying action on oil, and hence dries quickly; it possesses good covering properties, and it may be mixed with, or applied over, any of the other pigments without affecting them or being affected itself, with the exception of ultramarine, cadium yellow, and those pigments which contain sulphur. The disadvantages are stated by way of contrast as follows: Red lead is quite inadmissible as a water paint; it is influenced by sulphuretted hydrogen, and turns quite black under its influence; it sets quickly; it is somewhat difficult to work. The bright orange colour of red lead is sometimes objectionable. This may be avoided by mixing lampblack in a proportion not exceeding 1 oz. to the pound. When used as paint it must be mixed fresh every day, or even several times a day, as it sets so quickly. About a gallon of linseed oil is required to grind 100 lb. of red lead. For painting articles which are to be subjected to a good deal of rough usage and hard wear, such as agricultural implements, carts, waggons, etc., red lead is generally used. It is also employed to considerable extent for a priming coat (*q.v.*) on woodwork, being mixed with white lead. It should not, however, be used under white work. The fact that it hardens quickly causes it to be used largely in various cements. *See also* LEAD COMPOUNDS.

Red Oils (*Chem. Tech.*) Crude oleic acid, obtained in the manufacture of stearine.

Red Oxide of Copper (*Min.*) *See* CUPRITE.

Red Oxide of Zinc (*Min.*) *See* ZINCITE.

Red Phosphorus (*Chem.*) *See* PHOSPHORUS.

Red Precipitate (*Chem.*) A common name for the red form of mercuric oxide. *See* MERCURY COMPOUNDS.

Redruthite (*Min.*) *See* CHALCOCITE.

—— (*Mining*). *See* COPPER GLANCE.

Red Sandstones. *See* BUILDING STONES.

Redshort (*Met.*) A term applied to iron or steel which cannot readily be forged or rolled at or above red heat. It is caused by the presence of 0·2 per cent. of sulphur in wrought iron or steel; 0·5 per cent. of copper in the case of iron; 0·2 per cent. of antimony in either iron or steel. Pig iron containing 0·3 per cent. of sulphur invariably yields redshort steel by the Bessemer or Siemens processes. In steel 0·5 per cent. of silicon causes redshortness. *Compare* COLDSHORT.

Red Silver Ores (*Min.*) Under this term are included PYRARGYRITE *and* PROUSTITE (*q.v.*)

Reduced Work (*Build.*) A wall the standard thickness of one and a half bricks. All walls are reduced to this thickness for the purpose of measurement. *See* ROD.

Reducing Agents (*Chem.*) *See* REDUCTION.

Reducing Furnace (*Met.*) A furnace in which ores of metals are reduced, *i.e.* the combined oxygen is removed. A blast furnace is therefore a reducing furnace.

Reducing Mixtures (*Chem.*) A mixture of two or more substances, employed to effect Reduction (*q.v.*) A substance capable of acting as a flux (*q.v.*) is often included in the mixture.

Reducing Pipe, Joint, *or* Socket. A pipe or joint, etc., used to connect together two pieces of piping of different diameters.

Reduction (*Chem.*) This process is the converse of oxidation (*q.v.*) It may consist in any one of the following operations: (1) removal of oxygen from a compound; (2) addition of hydrogen to a compound; (3) changing an "-ic" salt to an "-ous" salt; (4) replacing another element by hydrogen. Examples: (1) when carbon dioxide is passed over red-hot carbon it loses an atom of oxygen, $CO_2 + C = 2CO$. Many metallic oxides when heated with carbon or in a stream of hydrogen or carbon monoxide give up oxygen, and are reduced either to the metal or to a lower oxide; thus ferric oxide, cupric oxide, zinc oxide, stannic oxide, lead oxide all give the metal; but the oxides of manganese are only reduced as far as manganous oxide, MnO. As an organic example the removal of oxygen from azoxybenzene (*q.v.*) by distillation with iron filings may be given. (2) This may occur with or without resolution of the original compound into simpler ones. Aldehydes unite with hydrogen directly to form alcohols:

$$R - C \begin{matrix} \diagup H \\ \diagdown O \end{matrix} + H = R - C \begin{matrix} \diagup H \\ - H \\ \diagdown OH \end{matrix}$$

ketones (*q.v.*) to form secondary alcohols. Aromatic hydrocarbons and their derivatives are frequently reduced by sodium and alcohol or by hydriodic acid to hydro-aromatic compounds; for examples *see under* NAPHTHYLAMINES *and* PHTHALIC ACID. Hydrazines are reduced by tin and hydrochloric acid to amines and ammonia; *e.g.*

$$\underset{\text{Phenylhydrazine.}}{C_6H_5 . HN . NH_2} + 2H = \underset{\text{Aniline.}}{C_6H_5NH_2} + NH_3.$$

(3) This change can be effected in some cases in the dry way, as when hydrogen is passed over heated chromic or ferric chlorides. It is commonly effected in solution when the reaction is an ionic reaction and the actual change consists in the removal from a positive ion of one or more quantities of electricity each equal to that carried by the hydrogen ion; *e.g.* the reduction of ferric chloride solution by zinc and dilute sulphuric acid may be represented thus:

$$\underset{\text{Metal.}}{Zn} + 2\overset{+}{H} + \overset{=}{SO_4} = \underset{\text{Ion.}}{\overset{++}{Zn}} + \overset{=}{SO_4} + \underset{\text{Free hydrogen.}}{H_2}$$

$$2\overset{+++}{Fe} + 6\overset{-}{Cl} + H_2 = 2\overset{++}{Fe} + \underset{\text{Ion.}}{2\overset{+}{H}} + 6\overset{-}{Cl}$$

(4) Common examples of this kind of reaction are the replacement of chlorine or oxygen by hydrogen; *e.g.* methyl iodide is reduced by the zinc copper couple in presence of alcohol to methane; trichloracetic acid in aqueous solution is reduced to acetic acid by potassium amalgam; succinimide,

$$\left.\begin{matrix} CH_2 - CO \\ | \\ CH_2 - CO \end{matrix}\right> NH$$

can be reduced to 2-pyrrolidine,

$$\left.\begin{matrix} CH_2 - CO \\ | \\ CH_2 - CH_2 \end{matrix}\right> NH$$

or to pyrrolidine—

$$\left.\begin{matrix} CH_2 - CH_2 \\ | \\ CH_2 - CH_2 \end{matrix}\right> NH$$

See PYRROLE. Reagents which effect reductions are called reducing agents; they are, of course, substances which can themselves be somewhat readily oxidised. Examples of reducing agents are hydrogen, carbon, sulphurous acid, sulphuretted hydrogen, stannous chloride, hydriodic acid, sodium stannite, zinc dust, aldehydes.

Reduction Factor (*Elect.*) If a unit current in a galvanometer produce a magnetic field of strength G, and H be the strength of the controlling field (due to the earth, control magnet, etc.) at right angles to this, the ratio $\frac{H}{G} = k$ is termed the Reduction Factor of the galvanometer. If the deflection δ be proportional to the current C, then $C = k\delta$; in the case of a tangent galvanometer, $C = k \tan \delta$. *See also* GALVANOMETERS.

Reduction of Area. When a piece of metal is drawn out in a testing machine the area of its cross section becomes reduced; the amount of reduction which occurs before the specimen breaks is a good test of the quality of the metal.

Redundant (*Music*). A term applied by some writers to augmented intervals.

Redwood. *See* WOODS.

Reed (*Carp. and Join.*) A bead without a quirk.

—— (*Music*). A thin piece of cane or metal which vibrates and produces a musical sound when a column of air passes it. Reeds are of two kinds—free reed, as in the harmonium (*q.v.*, p. 442), and the striking reed, as in the organ (*q.v.*, p. 441). *See also* REED INSTRUMENTS, p. 431.

—— (*Weaving*). A comb-like instrument with splits or dents of varying gauge. It is fixed in the loom sley, and serves three useful purposes, *viz.* (1) it maintains the warp threads in corresponding positions throughout weaving, and fixes the gauge or set of the cloth; (2) assists in the beating up; (3) acts as a guide when the shuttle is crossing. Also used in the preparatory processes for regulating the width of warp threads. Reeds were first made of metal by John Kay, the inventor of the fly shuttle. *See* LOOM.

Reed Marks, Reedy (*Weaving*). Defective streakiness warpways of the cloth, due to the threads rolling in the splits of the reed, particularly in mat weaves. They may also occur in the direction of the weft, due to the reed cutting the picks of weft. The reverse of "cover" (*q.v.*)

Reef (*Mining*). (1) A lode or vein; (2) the outcrop of a vein.

Reel (*Textile Manufac.*) A skeleton cylinder on which yarn can be wound in 1 or $1\frac{1}{2}$ yard lengths, for the purpose of ascertaining its counts (*q.v.*)

Reeler (*Paper Manufac.*) Apparatus for working up the dry paper from the machine into a reel, for use on a Rotary printing press. *See* TYPOGRAPHY.

Reeling (*Cotton Manufac.*) Winding the thread by means of a reel from a ring bobbin or cop into a standard length, such as a "lea" or "hank," so as to be more convenient for dyeing purposes. Two forms of reeling are employed, *viz.* (*a*) straight reeling, (*b*) cross reeling.

—— (*Textile Manufac.*) The operation of reeling and hanking the yarns. Woollen yarns are hanked on the 1 yard reel, worsted on both 1 yard and 1½ yard, and cotton on the 1½ yard.

Reel of Paper (*Paper Trade*). The form in which paper is supplied for use on Rotary machines. It is printed in continuous lengths.

Refectory (*Architect.*) A hall in which meals were formerly taken.

Reference Marks (*Typog.*) *See* NOTES.

Refined Iron (*Met.*) White cast iron which has been partially deprived of its carbon previous to the process of puddling (*q.v.*) The process termed REFINING (*q.v.*) is dispensed with when the pig iron is converted into wrought iron by the process of PIG BOILING or WET PUDDLING (*q.v.*)

Refiner (*Paper Manufac.*) A conical shaped apparatus similar to the "perfecting engine" used for beating pulp.

Refinery. A place in which the processes of Refining (*q.v.*) are carried on.

Refining. A term applied in a very wide manner to various purifying processes, *e.g.* the final stages in the manufacture of spirits, sugar, metals, etc.

Refining of Iron (*Met.*) Pig iron is heated in a furnace resembling a cupola, or small blast furnace, but with a number of tuyères which point downwards towards the hearth, so as to cause an abundant supply of air to play on the molten iron. A great deal of the carbon and most of the silicon are oxidised and removed from the iron, which is then run into moulds, suddenly cooled by water, and broken up, when it is ready for Puddling (*q.v.*) *See also* IRON.

Reflecting Galvanometer (*Elect.*) *See* GALVANOMETERS.

Reflecting Telescope (*Astron.*) A telescope in which a mirror is employed for obtaining the primary image. They take several forms, the chief of which is known as a Newtonian.

Reflection (*Phys.*) If any disturbance, whether of the nature of wave motion or of actual motion of translation of matter, impinge upon a surface which changes the direction of motion of the disturbance, and sends it back through the medium on the same side of the surface as that on which it was originally travelling, the disturbance is said to be REFLECTED. The surface which produces the change in direction is said to be a REFLECTING SURFACE.

Reflection Grating (*Phys.*) *See* DIFFRACTION GRATING.

Refracting Telescope (*Astron.*) A telescope in which a lens is employed for obtaining the primary image.

Refraction (*Phys.*) If a disturbance pass from one medium to another, the direction of propagation generally undergoes a sudden change; the ray (*q.v.*) is turned through an angle at the point where it meets the surface of separation of the two media. This bending, or change of direction, is termed REFRACTION. The same term is also applied to other phenomena having a certain resemblance to the foregoing, *e.g.* the change in direction of the lines of flow of an electric current when it passes from any conducting medium to another of different conductivity, or of the lines of electric or magnetic force in passing from one medium to another of different Specific Inductive Capacity (*q.v.*) or different Permeability (*q.v.*) respectively.

Refractive Index (*Phys.*) *See* INDEX OF REFRACTION.

Refractometer (*Phys.*) An instrument for the measurement of the refractive index (*q.v.*) The INTERFERENCE REFRACTOMETER depends upon the interference of two beams of light, derived from the same original source, when a transparent medium is interposed in the path of one of the beams.

Refractory (*Met.*) Applied to infusible substances such as fireclay, lime, etc., which are used as crucibles and furnace linings.

Refrigeration. Cooling to a low temperature. The process is extensively applied to articles of food (meat, etc.) in order to prevent decomposition during transit.

Refrigerator. (1) A cold chamber for storage of perishable foods, etc. (2) A machine for the artificial production of cold. On a large scale this result is produced by allowing a compressed gas to expand rapidly in coils surrounded by brine or air. Heat is absorbed and refrigeration effected. The compression of the gas is effected by pumps driven by power, and the heat produced by the compression is carried off by means of water jackets through which a continuous stream of water circulates. Ammonia gas or carbon dioxide is found to be very convenient for this use; after expansion, it is again compressed, and used over and over again with little or no loss of gas.

Refuse. (*a*) Street. By Sec. 29 of the Public Health (London) Act, 1891, it is the duty of the Sanitary Authority to collect and remove street refuse, defined by Sec. 141 to consist of dust, dirt, rubbish, mud, road scrapings, ice, snow, and filth. (*b*) House. Sec. 30 requires the removal by the Sanitary Authority, at proper periods, of all house refuse, defined as ashes, cinders, breeze, rubbish, night soil, and filth, but does not include trade refuse. (*c*) Trade Refuse, that is, the refuse of any trade, manufacture, or business, or of any building materials, must be removed by the Sanitary Authority at the request of the owner or occupier of the premises, and on payment of a reasonable sum for such removal (Sec. 34). (*d*) Offensive Refuse. It is not the duty of the Sanitary Authority to remove such refuse, but the Sanitary Inspector shall serve a notice on the owner or occupier of the premises where it exists, requiring its removal. If within forty-eight hours the notice is not complied with, the Sanitary Authority may remove and sell or otherwise dispose of it (Sec. 35).

Regal, Regals (*Archæol.*) A miniature reed-pipe organ of the sixteenth and seventeenth centuries. It was supported by the player, the bellows being manipulated by one hand and the manual played by the other.

Regelation (*Heat*). If ice be subjected to pressure, the freezing point is lowered, and some of the ice melts. On the withdrawal of the pressure, freezing occurs again; to the latter process the term Regelation is applied.

Regenerative Furnace. A furnace in which hot waste gases are utilised to heat the incoming air, or, in the case of gaseous fuel, the mixture of air and combustible gases. They first pass through a chamber filled with open brickwork, to which a large portion of the heat is given up; when the chamber is sufficiently heated, the air, or mixture of air and combustible gases intended to supply the furnace, is caused to pass through it, while the waste gases flow through a second brickwork chamber or REGENERATOR. Thus the air and gas entering the Regenerative Furnace are already at a high temperature, and economy of working results.

Regenerator (*Met., etc.*) The chamber of a Regenerative Furnace (*q.v.*) It is filled with brickwork arranged as chequer work, *i.e.* with spaces between the bricks, so as to present a large amount of surface to the gases.

Register (*Typog.*) Accurate adjustment in printing the second side of a page, or the "re-iteration" of a sheet, as it is sometimes termed. Perfect registration is necessary in order that the margin of the pages may be exactly even when the sheets are folded. In colour printing, the absolute agreement of two formes which is necessary when one colour is imposed on another.

Register Sheet (*Typog.*) The sheet or sheets of paper used in making register, usually of a common quality when the paper on which the work is to be printed is expensive.

Register Stove (*Build.*) A stove with an iron flap, the REGISTER, placed over the opening of the flue, which it serves to close.

Reglet (*Architect.*) A flat, narrow moulding used to separate larger mouldings, or to form frets, etc.

—— (*Typog.*) A kind of furniture (*q.v.*) made of wood, and of equal thickness all its length. It comprises all sizes up to "narrow" or three line pica.

Reguardant (*Her.*) Looking back. *See* LION REGUARDANT.

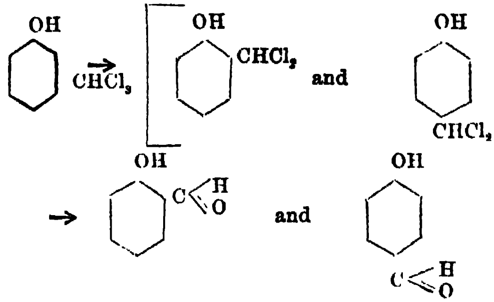
Regulator Valve (*Eng.*) A valve, controlled by the driver, which regulates the supply of steam to the cylinders of a locomotive.

Regulus (*Met.*) A mass of partly smelted ore or partly purified metal.

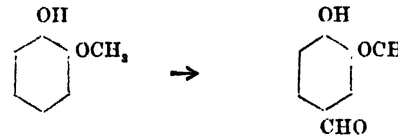
Reheating (*Met.*) The process of heating steel ingots in the mill furnace before rolling. It is often avoided by the use of SOAKING PITS (*q.v.*)

Reichardite (*Geol.*) A mineral found in the Carnalite region of Stassfurt. Composition: $MgSO_4$, 48·78 per cent.; H_2O, 51·22 per cent.

Reimer's Reaction (*Chem.*) A general reaction for the introduction of the aldehyde group into certain classes of aromatic compounds, especially phenols. For example, when phenol, chloroform, and an aqueous solution of caustic soda are boiled together under a reflux condenser a mixture of ortho- and para-hydroxybenzaldehydes is obtained, the former of which is volatile in steam—

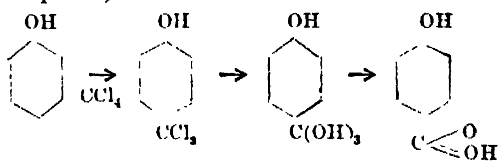


Other phenols can be used in place of ordinary phenol; for instance, if guaiacol is used, vanillin can be obtained.



Guaiacol.

Quite analogous is the formation of parahydroxybenzoic acid (with a little of the ortho-compound) by boiling phenol with carbon tetrachloride and alcoholic potash).



Reins (*Eng.*) A term sometimes applied to the handles of a blacksmith's tongs.

Reiteration (*Typog.*) The term applied to the "second" side of a sheet that has to be printed.

Relative Humidity (*Meteorol.*) *See* FRACTION OF SATURATION.

Relative Minor (*Music*). A key having the same signature as the relative major, but whose tonic or keynote is a minor third lower, *e.g.* A major, F♯ minor.

Relay (*Elect.*) A device consisting of an electromagnet through which a feeble current passes, causing the magnet to actuate a switch or contact maker by which another (and usually more powerful) current is turned on. The latter current, which is supplied by a local battery, acts on any required apparatus, *e.g.* a telegraphic receiving instrument.

Release (*Eng.*) The opening of the exhaust port of an engine cylinder to allow the escape of the steam or other gas at the end of the stroke.

Relief (*Art*). (1) In painting, the apparent projection obtained by modelling, or the gradation of tones or tints. (2) In Sculpture, the projection of figures beyond the ground or plane on which they are formed, *e.g.* alto-relievo, basso-relievo, mezzo-relievo (*q.v.*) (3) In architecture, the projection of mouldings and systems of ornament from the surface of a wall or façade.

Relief Printing (*Typog.*) A term used to distinguish letterpress from lithographic or plate printing.

Relieving Arch (*Build.*) *See* DISCHARGING ARCH.

Religioso (*Music*). In a devotional manner.

Reliquary. A depository or casket in which relics are preserved; a shrine.

Reluctance (*Elect.*) *See* MAGNETIC RELUCTANCE *and* MAGNETIC CIRCUIT.

Remanence (*Elect.*) The property possessed by a magnetic body (*e.g.* iron) of retaining a certain amount of magnetism after the original magnetising influence has ceased to act.

Removes (*Typog.*) A term used to express the gradations between type of different sizes.

Renaissance (*Art, etc.*) The period of transition from mediæval to modern times. In Europe this occurred between the beginning of the fifteenth and the end of the eighteenth century.

Renaissance Architecture. The revival of the use of classic forms which was one of the results of an intellectual movement beginning in Italy during the thirteenth century is known as the Renaissance. Even in Italy, however, it was not until the fifteenth century that Renaissance art asserted itself. The decline of the Renaissance in Italy began with the Baroque period, 1550—1600 A.D., and the Italian Renaissance ended with the Rococo style, a vulgar and debased architecture which obtained during the seventeenth century. English architecture began to show signs of the Renaissance in the Tudor period. The Tudor style obtained during the first half of the sixteenth century, and can be looked upon as a period of transition. In the Elizabethan period (1558 - 1603) the pointed arch is no longer used, and the orders are introduced as ornamental features. In the Jacobean style (1603—1625) classic details are more in evidence. Inigo Jones and Sir Christopher Wren were responsible for the principal buildings which were erected during the period in which the classic style—for which Gothic architecture made way at the close of the Jacobean period—obtained.

Render (*Chem. Tech.*) To extract and refine the fat, etc., from animal tissues by heat.

Rendering (*Plastering*). The first coat of plaster laid on a brick wall.

Rennet. A preparation of the mucous membrane of the stomach of a calf: used to produce coagulation of milk in making cheese, etc.

Rep (*Silk Manufac.*) A corded silk fabric showing a bold rib. Made with a binder warp in addition to the ground and with two shuttles, one carrying a coarse round thread of worsted or cotton, the other a fine thread or divider. If made face upwards the whole of the ground warp is raised for coarse shoot, 1st pick, and the whole of the binder cane for divider, 2nd pick.

—— (*Textile Manufac.*) A worsted, cotton, or silk fabric in which there are lines formed across the fabric, and in which only the warp shows on the face.

Repeat (*Music*). This is indicated by dots placed at a double bar:

 or 

and signifies that the section on the side of the double bar on which the dots occur is to be played twice. In the performance of the minuet or scherzo it is customary to omit the repeats in the Da Capo (*q.v.*) after the Trio.

Replacing Switch (*Eng.*) A device with an inclined plane by means of which derailed cars are placed upon the rails again.

Replenisher (*Elect.*) A small electrostatic machine for charging the needle of an electrometer.

Replica (*Art*). A facsimile of a work executed by the artist who produced the original. *Cf.* COPY.

—— (*Music*). Repeat. *Senza replica,* without repeats. *See* REPEAT.

Repose (*Art*). The term is applied to a work of art the details of which are well balanced and in harmony, no one feature unduly attracting the attention of the observer.

——, **Angle of** (*Phys., etc.*) The maximum angle at which any surface may be inclined without causing a body which rests on the surface to commence to slide down is termed the Angle of Repose. The term is commonly applied in practice to the maximum angle of inclination of the sides of a heap of loose material (*e.g.* earth, sand, etc.)

Repoussé. A style of decoration effected on metal work by beating the metal on one side with a hammer until a rough image of some desired figure or design is produced, which is then chased (*q.v.*)

Representative Fraction. *See* SCALE DRAWING.

Reredos (*Architect.*) The screen or wall panelling behind an altar in a church.

Reseau (*Astron.*) A network of lines forming small squares impressed on a glass plate. Used extensively in photographic star charting.

Reserve of Buoyancy (*Phys., etc.*) When a body floats in a liquid, and is only partially immersed, it is said to have a Reserve of Buoyancy. Further immersion can only be effected by the application of additional force (acting downward), and this force is opposed by an increased upward force due to the extra displacement of liquid.

Reservoirs (*Civil Eng.*) For the storage of water are made by excavation or embankment, the floor and sides being lined with concrete or well puddled clay. Service reservoirs should be covered and ventilated, and the water from the supply reservoir passed through filter beds of sand before entering the service reservoir for distribution. They should be placed on as high ground as possible to give a sufficient pressure of water, so that the supply may be assured by gravitation; otherwise the water must be raised by pumping.

Residual Charge (*Elect.*) A small charge remaining in a Leyden Jar or other condenser after it has been discharged.

Residual Gases. The gaseous products of combustion, together with any unburnt and incombustible gases, which remain in a gas engine cylinder or the bore of a gun, etc., after explosion.

Residual Magnetism (*Elect.*) The magnetism which is retained by iron, etc., after the magnetising force has ceased to act on it.

Resilience (*Phys.*) In general language the reaction of a body against a force producing distortion: in scientific terminology, the work expended in producing a given strain. This work is stored up in the body and can be recovered if the stress has not been increased beyond the elastic limit. The term Resilience is frequently restricted to the maximum amount of work which can be stored up in a strained body without exceeding the elastic limit.

Resilience (*Eng.*) If p be the stress when the elastic limit (*q.v.*) is reached, E the coefficient of elasticity, and V the volume of the body, then the Resilience $= \frac{1}{2}\frac{p^2}{E}V$. The quantity $\frac{p^2}{E}$ is termed the MODULUS OF RESILIENCE, and p the PROOF STRESS.

Resin *or* **Rosin** (*Music*). A preparation obtained by dissolving ordinary rosin and straining it thoroughly. The best is made from Venetian turpentine, should be quite transparent, and when crushed not sticky. It is rubbed on the hair of stringed-instrument bows to facilitate the setting of the strings in vibration.

Resins. It is very difficult to define a resin. It is undoubtedly an exudation from the trunk and limbs of trees, existent or non-existent; but these exudations vary so much in all their properties that the terminology of them is wide, complicated, and in many cases contradictory. On the whole, it seems advisable to adopt the definition to be presently given, and to be guided by it in the subsequent remarks. The literature of the subject is scanty, and is the work of writers who have evaded the difficulty of definition. We propose to define a resin by three properties, as follows:

(1) It is a vegetable production.

(2) It solidifies after exudation from the tree.

(3) It is insoluble in water, but soluble in various organic liquids, such as chloroform, alcohol, oils, etc.

The second of these three essentials serves to establish a distinction between resins and balsams, such as copaiba and tolu, which are very closely related to the resins, and may, in fact, be regarded as substances intermediate between them and the essential oils. The third separates the resins from the gums proper, *e.g.* arabic and tragacanth, which are also vegetable exudations. The difficulty of the subject is well shown by the frequent use of the term "gum resin" and by the fact that the German word *gummi* means gum and also indiarubber, which may be regarded as a special kind of resin. In fact, there is a regular gradation from hard resins to soft resins, oleo resins, balsams, and essential oils; but with such small differences that it is practically impossible to draw any but arbitrary lines of demarcation. There is little doubt that the essential oils are the original material from which Nature has elaborated the balsams and resins by processes at present imperfectly understood, and therefore they cannot yet be reproduced artificially. There seems to be a strong probability that the action of atmospheric oxygen has played a considerable part in their formation, and that this formation has much analogy with the phenomena attending the solidification of a drying oil; but the fact remains that very little is known about the matter. The oxidation theory was, in fact, suggested by the behaviour of drying oils. Resins are classified as hard and soft, fossil and recent. The HARD RESINS, generally speaking, are also the fossil resins. The term fossil (dug up) does not necessarily mean that the resin won from the ground is the product of trees now extinct. It may be that this is sometimes the case. Amber, for instance, is probably the product of extinct trees. Nevertheless there are places, *e.g.* in New Zealand, where fossil resin is dug up on the sites of perished forests, and this product is indistinguishable from the fresh resin obtained from living trees in other parts of the country. The chief hard resins are amber and copal. AMBER is a fossil resin from an unknown tree. It was formerly dredged up on the southern shore of the Baltic, being washed by the waves from the submerged sites of ancient forests. Most of it is now, however, obtained by mining. It is used in fancy work, especially for the mouthpieces of pipes and cigar-holders, and for making the best and most expensive varnishes. Beads, too, are made of it. Its Greek name, *Electron*, has given us the word electricity, because it would seem that electrical attraction was first noticed in a piece of this substance which had been subjected to friction. COPAL comes from various trees. The best resins, those of Zanzibar and Mozambique, are the products of the gums *Trachylobium.* These give the hard copals. Animi or Indian copal, also known as Manila copal, is a softer resin, produced by *Valeria Indica.* The difference in nomenclature is geographical and commercial rather than a distinction of intrinsic value. Kauri or New Zealand copal is both a fossil and a recent resin. The African copals are dug up from depths of 3 or 4 ft. in districts from which the trees of their origin have entirely disappeared or perhaps become totally extinct; but in New Zealand we have the Kauri gathered from the living trees in one place and dug out of barren soil in another. Fossil copal has been dug out of the London tertiaries at Highgate. South American copal is a soft copal like animi and manila, but from a different tree, *viz. Hymenæa coubaril.* DAMMAR is practically equivalent to Kudri copal, and the difference in nomenclature is geographical only. *Dammara australis* is the tree responsible for both sorts. Alive it produces dammar. Kauri is the legacy of dried resin left behind by former generations of the same tree. It should be noted that the name Agathis is in some books substituted for the older name Dammara. These hard resins have the curious property of requiring to be heated before they can be dissolved in oil and turpentine for varnish making. "Copal running," as the process is called, requires a fairly high temperature, and yields a distillate containing substances of some value, although the vapours are usually allowed to escape into the open air. The only SOFT RESIN calling for notice is the chief of all the resins, and it lends itself to a larger variety of uses than its congeners. While other resins are restricted in their use to the making of varnishes, rosin (pine tree resin), while doing good service to the varnish maker, is largely used as a cement and for the preparation of resinates. It makes, like shellac, an excellent medium for stopping leaks in china and earthenware vessels. Shellac, which is largely used for stopping up cracks in jugs, teacups, etc., as it will stand hot water, is distinctly inferior to rosin for the purpose. Colophony, or rosin, is the coagulated exudation obtained from cuts in the bark of trees belonging to several species of Pinus, largely grown in America and on the west coast of France. The crude resin yields on distillation oil of turpentine first and then a mixture of liquids of higher boiling temperature known as rosin oil. This oil is largely employed in making the cheaper varnishes, lamp-black for printers' ink, and also, in some places on the Continent, illuminating gas. It is not used, however, for this last purpose in Great Britain, although very high illuminating power is claimed for the gas. The final residue of the distillation is pitch, which is used for caulking seams and for waterproofing the inside of casks. It must not be confounded with coal-tar pitch. Colophony is largely used for varnish making, for making violin bows grip the strings, as a flux by plumbers in

soldering, for filling soaps, and for the preparation of resinates. All cheap varnishes contain colophony, and one of the "copal" varnishes, for which high prices are charged, contains little else except the solvent. The use of rosin in soapmaking is one of its most important applications. Boiled with an alkali, it produces an alkaline resinate, which has at least this much of a soap about it, that it lathers well. This circumstance, together with the fact that rosin is much cheaper than soap, has naturally drawn the attention of soap boilers to it. The alkaline resinates have, however, a much more legitimate use as a raw material for the preparation of the resinates of heavy metals, such as manganese and lead. These resinates have an extended application in the manufacture of driers and of paints. We may conclude with a brief notice of LAC. This does not conform altogether to the first requisite of a resin as defined above, since, although it is primarily a vegetable substance, it is worked up and secreted by an insect; still it has a close connection with the true resins. The products of the lac insect are purified first to seed lac and finally to shell lac (shellac). Spirit varnishes are made from it and also French polish, and it is the chief ingredient of sealing wax. It is the only animal product which conforms to the second and third requisites of a resin.—A. S. J.

Resist. A substance or composition which is temporarily applied to certain parts of the surface of another substance to prevent an acid, dye, mordant, etc., from affecting those parts, *e.g.* the wax applied in a thin coat to glass previous to etching. *See* GLASS MANUFACTURE.

Resistance (*Elect.*) The ratio of a constant electromotive force to the steady current produced by it in any conductor is termed the ELECTRICAL RESISTANCE of the conductor. If the length of a conductor be l and its area of cross section a, then its resistance R is given by the formula $R = \sigma \frac{l}{a}$. If l and a are each unity, then σ is the resistance of the conductor. It is termed the SPECIFIC RESISTANCE.

—— (*Eng.*) That which opposes the action of a force; it is therefore a force itself. The term is applied especially to frictional forces.

——**, Measurement of** (*Elect.*) The measurement of the electrical resistance of a conductor is effected in practice by comparison with a known resistance. The principal methods by which this comparison is made are as follows: (1) METHOD OF SUBSTITUTION: The unknown resistance is connected in series with a cell or battery of constant electromotive force and an ammeter or a galvanometer, by which the current which flows through the circuit can be measured. Let X be the value of the resistance, E the E.M.F., and C the current, S the resistance of the rest of the circuit. Then by Ohm's Law (*q.v.*)

$$C = \frac{E}{X + S}$$

An adjustable resistance or set of resistances is now substituted, and its value adjusted until the current has the same value as before. Let R be this resistance. Then

$$C = \frac{E}{R + S}$$

But as the current is unchanged in amount, and E is constant, $X + S = R + S$ or $X = R$. If R cannot be adjusted to give the same current, the values C_1 and C_2 of the current must be observed; then

$$\frac{C_1}{C_2} = \frac{\frac{E}{X+S}}{\frac{E}{R+S}} = \frac{R+S}{X+S}$$

To find X in terms of R it is now necessary that S be known. In the application of this method to the comparison of very high resistances, which is its chief practical use, the value of S is very small compared to R and X, and in this case

$$\frac{C_1}{C_2} = \frac{R}{X}$$

(2) METHOD OF FALL OF POTENTIAL: If C be the current in a conductor of resistance R, the difference of potential E_1 between the ends of the conductor is CR. If the same current flow through another conductor of resistance X, the difference of potential E_2 is CX. Thus

$$\frac{CX}{CR} = \frac{E_2}{E_1} = \frac{X}{R}$$

The known and unknown resistances are connected in series with each other and with a constant battery; the differences of potential E_1 and E_2 are observed by means of a voltmeter or a high resistance galvanometer. This method is used for the comparison of very small resistances. (3) MEASUREMENT BY WHEATSTONE'S BRIDGE: This is the method which is used in practice for the measurement of the great majority of resistances; the form known as the Post Office Box can be used for measuring resistances from ·1 ohm to 1,000,000 ohms, though the extreme range is not used when considerable accuracy is required. The method is described under WHEATSTONE'S BRIDGE (*q.v.*)

Resistance Coil (*Elect.*) A coil of insulated wire whose resistance has been adjusted to a stated value. In forming the coil a wire whose resistance is somewhat greater than that of the finished coil is first doubled in the middle, bringing the two ends together. The doubled wire is then wound on a reel, and the resistance measured, the wire being shortened until the proper value is attained. The ends are then connected to terminals placed on the top of the reel, and the whole enclosed in a suitable case.

Resolution (*Music*). A term applied to the proper and satisfactory progression of discords (*q.v.*)

Resolution of a Force. Finding the magnitude and direction of two or more forces such that their resultant (*q.v.*) is identical with the force which is being resolved. The separate forces, which may be substituted for the given force, are termed its COMPONENTS. If they are at right angles to each other, they are termed RECTANGULAR COMPONENTS. If f be the given force, and θ the angle which one component makes with the original force, then the value of this component is $f \cos \theta$, and that of the other component at right angles to it is $f \sin \theta$.

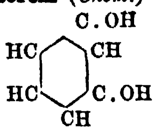
Resonance (*Phys.*) If any body (or system of bodies) be acted upon by a succession of impulses or vibrations, which recur at intervals corresponding to its own natural period of vibration, it will itself be caused to vibrate. This is termed RESONANCE. The phenomenon is very easily observed in the case of sound: *e.g.* a stretched string is readily set in vibration if a note of the same pitch (frequency) as

its own fundamental tone be sounded in the vicinity. Resonance is often made use of in the detection of vibrations which are too feeble to be detected by the unaided ear.

Resonant. As applied to substances, *e.g.* porcelain, metals, etc., indicates that they give a ringing sound when struck.

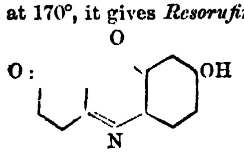
Resonator (*Phys.*) An object used in the detection of vibrations by Resonance (*q.v.*) In acoustic experiments, hollow vessels of approximately spherical form are often used, as their overtones (*q.v.*) are not readily produced, and therefore they resound to their fundamental tone only.

Resorcin (*Chem.*)



(Metadihydroxybenzene.)

A white solid crystallising in needles or plates; melts at 118°; boils at 277°; soluble in water, alcohol, ether; insoluble in chloroform; tastes sweet; it is a powerful antiseptic, and is used in medicine in some skin diseases. Ferric chloride gives a dark violet colour with a solution of resorcin. Reduces boiling Fehling's solution and boiling ammoniacal silver nitrate. With bromine water it forms tribromresorcin (MP 111°), which is insoluble in water (basis of method for estimation). Fused with caustic soda, it gives a 65 per cent. yield of phloroglucin, a little pyrocatechol and tetroxydiphenyl. Heated with phthalic anhydride alone or with a little sulphuric acid, it forms fluorescein (*q.v.*); other dibasic acids give similar compounds—*e.g.* succinic and tartaric acids. Heated with nitrobenzene and concentrated sulphuric acid at 170°, it gives *Resorufin*



which forms small brown needles, which dissolve in alkalis with a crimson colour showing scarlet fluorescence, and on bromination form *Resorcin blue*, which is tetrabromresorufin—a dye giving blue shade with brown fluorescence on silk and wool. *See also under* LACMOID. Resorcin is obtained when certain resins, especially asafœtida and galbanum, are fused with caustic potash. It is also obtained when many meta-disubstituted benzene derivatives are fused with caustic soda; also from some ortho- and para-derivatives. On the large scale it is made from benzene by heating with fuming sulphuric acid to form metabenzenedisulphuric acid, which is made into the calcium salt with chalk, then into the sodium salt with sodium carbonate,—the sodium salt is fused with caustic soda. From the aqueous solution amyl alcohol dissolves out the resorcin.

Resorcinol (*Chem.*) *See* RESORCIN.

Respond (*Architect.*) A half pillar attached to a wall and supporting an arch. It usually occurs at each end of a range of pillars.

Rest (*Eng.*) A support for a tool, especially a turning tool. *See* HAND REST, SLIDE REST, *etc.*

—— (*Music*). A sign indicating silence. There is a rest corresponding to each note and having exactly the same time duration as that note. The following is a list of rests with the respective shapes:

The Large or Maxima. The Long. The Breve.

The Semibreve. The Minim. The Crotchet. The Quaver.

The Semiquaver. The Demi-semiquaver. The Hemidemi-semiquaver.

In modern music it is usual to mark rests of more than two bars' duration thus, placing the number of bars over:

17

The semibreve rest is used for a complete bar's rest in either triple or common time.

Restitution, Coefficient of (*Mech.*) If two elastic spheres collide, their relative velocity after impact bears a certain ratio to their relative velocity before impact: this ratio is termed the COEFFICIENT OF RESTITUTION.

Restrainer (*Photo.*) *See* RETARDATION.

Restraining (*Photo.*) *See* RETARDATION.

Resultant. The Resultant of a system of forces is that single force which, when acting alone, produces the same effect as the separate forces, so far as regards the motion of the body which is acted on. (It does not follow, however, that the resultant will produce the same stresses in the body as the separate forces do.) The resultant of two velocities, accelerations, or other vectors (*q.v.*) is obtained in a manner similar to the resultant of two forces.

Retaining Rings (*Eng.*) Flange rings used to bind together the tyre and the central portion of railway wheels when built with wooden bodies.

Retaining Wall. A wall built to resist the pressure of earth or water.

Retardation. In general the checking or slowing down of any movement, or the application of a force or other agent which causes such checking.

—— (*Music*). A term applied by some musicians to suspensions which resolve upwards instead of downwards. *See* SUSPENSIONS.

—— *or* **Restraining** (*Photo.*) Causing a developer to act more gradually than it would otherwise do, by the addition of some substance (*e.g.* potassium bromide), which is termed the RESTRAINER *or* RETARDER.

Retarder (*Photo.*) *See* RETARDATION.

Retarders (*Eng.*) A flat strip of metal twisted into an elongated spiral, and placed in boiler tubes to increase the heating action of the furnace gases and break up the "steam lines." Sometimes they are made of fireclay; there are various patented forms.

Retarding Coil (*Elect.*) A choking or impedance coil.

Reticulated. Resembling network, having lines or veins crossing like a net.

Reticulated Tracery (*Architect.*) A form of tracery resembling network, used in the windows of the Decorated period of Gothic architecture.

Retort (*Chem., Met., etc.*) A vessel in which a substance is heated in order to cause a volatile constituent to be given off so that it may be condensed and separated from the original body. Retorts are made in a great variety of forms and many different materials, according to the purpose for which they are intended.

Retorted (*Her.*) Intertwined frettewise. Branches of trees are sometimes thus blazoned.

Retouching (*Art*). A modification or improvement carried out in a work of art. An alteration made to a photographic *cliché* to remedy the modelling.

Retrograde Motion (*Astron.*) The apparent westward motion of planets which occurs periodically, owing to the movements of the earth and the planet.

Retting *or* **Rotting** (*Linen Manufac.*) The term applied to the process of steeping the flax stalks in water. This dissolves out the gummy matter which surrounds the fibre and enables the "bone" of the plant to be broken up and dispersed in the process of scutching, without causing any unnecessary waste of fibre. *See* LINEN MANUFACTURE.

Return (*Architect., etc.*) A change in direction of a moulding such as that frequently used in the termination of a hood mould (*q.v.*)

—— (*Plumb.*) The pipe in which the water returns to the boiler in hot water circulation.

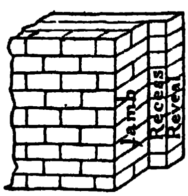
—— *or* **Point Pass** (*Textiles*). *See* ENTERING.

Returned Bead (*Carp. and Join.*) Beadwork on the side and edge of the same angle.

Returned Nosing (*Join.*) The moulding turned round the end of a stair tread.

Reuleaux's Valve Diagram (*Eng.*) *See* VALVE DIAGRAMS.

Reveal (*Build.*) The portion of the surface of a wall in an opening or recess (*e.g.* a door or window) between the edge or arris and the structure (*e.g.* window frame) placed in the recess. In the case of a window in an ordinary brick building the reveal is usually 4½ or 9 inches wide.

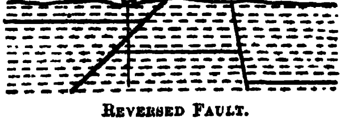


REVEAL.

Reverberatory Furnace. *See* FURNACES.

Reverse (*Coins*). The back of a coin or medal, *i.e.* the side opposite to the face or obverse (*q.v.*)

Reversed Faults (*Geol.*) In a normal fault the inclination of the plane of the fault is usually only a small number of degrees from the vertical, and is



REVERSED FAULT.

"forward at the foot," or advances in the direction of the downthrow side of the fault (*see b*, below). In a reversed fault the inclination or "hade" is in the opposite direction, so that a vertical shaft cutting the fault would pass twice through the same bed of rock, on either side of the fault, as at *a*.

Reversed Mould (*Foundry*). A kind of pattern made in metal or plaster, and used for producing a number of moulds when numerous similar castings are required.

Reverse Jaws (*Eng.*) Jaws on a lathe chuck which can be used for holding a ring or hollow cylinder, contact being made by the jaws with the inside of the ring, and the jaws moved outward till the object is firmly gripped.

Reversible Engine (*Phys.*) A "perfect engine" (*q.v.*) is said to be reversible, for the cycle of operations can (theoretically) be worked backwards. In this case the engine will take a quantity of heat H (measured in mechanical units) from the receiver or cool body, which is at a temperature θ_2, a certain amount of work, W, will be converted into an amount of heat *h*, and the larger amount of heat H + *h* will be given up to the hot body or source at a temperature θ_1. The ratio of work and heat is the same as in the case of the same engine when converting heat into work, *viz.*

$$\frac{W}{W+h} = \frac{\theta_1 - \theta_2}{\theta_1}$$

Reversible Reactions (*Chem.*) Reactions which may go, according to the conditions of experiment, in either direction. Thus, if sulphur dioxide is passed into water containing iodine in solution, we get the reaction

$$SO_2 + 2H_2O + I_2 = H_2SO_4 + 2HI.$$

But if strong sulphuric acid is added to a strong solution of hydriodic acid, we have the reverse of the above reaction—

$$H_2SO_4 + 2HI = SO_2 + 2H_2O + I_2.$$

Such reactions are usually written—

$$SO_2 + 2H_2O + I_2 \rightleftarrows H_2SO_4 + 2HI.$$

They are very numerous, and play a very important part in chemistry. *See* DISSOCIATION, MASS ACTION, PRECIPITATION.

Reversing (*Eng.*) Changing the direction of revolution of an engine or other mechanism.

—— (*Moulding*). Making an ordinary mould from a REVERSED MOULD (*q.v.*)

Reversing Back (*Photo.*) A frame (carrying the dark slide) which can be fixed to the camera in a horizontal or vertical position.

Reversing Countershaft (*Eng.*) A shaft from which a machine can be driven either by an open or a crossed belt, thus allowing the direction of rotation to be reversed.

Reversing Engine (*Eng.*) An engine which can be reversed, usually by LINK MOTION (*q.v.*) Locomotives, marine engines, etc., are almost invariably fitted with this gear; factory engines are not. Gas engines and steam turbines cannot, as a rule, be reversed by any form of valve or other gear.

Reversing Gear (*Eng.*) Any mechanism for reversing the direction of rotation. In engines it usually consists of LINK MOTION (*q.v.*) or a LOOSE ECCENTRIC (*q.v.*); in other machinery, of belts and countershafts or of trains of gear wheels.

Reversing Layer (*Astron.*) A thin stratum of a gaseous envelope lying just above the photosphere of the sun, the absorption of which is supposed by some astronomers to give rise to the Frauenhofer lines.

Reversing Link (*Eng.*) The slotted link used in LINK MOTION (*q.v.*)

Revise (*Typog.*) An impression of a forme taken for the purpose of seeing that all corrections have been made, etc. *See* READER.

Revolution (*Astron.*) The motion of one body round another, like the earth round the sun.

Revolving Boiler (*Paper Manufac.*) An apparatus used for digesting or boiling rags or straw.

Revolving Flats (*Cotton Spinning*). A series of slowly travelling bars on a carding engine, covered with wire filleting on their surfaces for the purpose of carding and cleaning the cotton as it goes over the large cylinder. Their travelling or revolving motion is for the purpose of subjecting a number of them in turn to a stripping process whilst the others are in action. By this means the filleting is always kept free from dirt, fluff, etc.

Revolving Furnace (*Met.*) A furnace containing either a flat circular hearth, revolving about an axis which is vertical or nearly so, or else having a tubular body, rotating about a horizontal or slightly inclined axis. Such furnaces are used in various processes for puddling or for steel manufacture. They are little used in this country.

Rh (*Chem.*) The symbol for RHODIUM (*q.v.*)

Rhætic Beds (*Geol.*) A geological formation of marine origin and of small thickness in Britain, which occupies a position between the base of the Lias and the top of the New Red. It is characterised nearly everywhere by the fossil mollusca *Avicula contorta*, *Cardium rhæticum*, and *Pecten valoniensis*. In the Rhætic Alps this formation attains to a much greater thickness.

Rhamnose (*Chem.*) $CH_3.(CHOH)_4.CHO$ (Isodulcite). A sugar which crystallises with one molecule of water in shining monoclinic crystals which show triboluminescence. On heating at 100° it loses its water of crystallisation, and on prolonged heating at this temperature forms an anhydride; soluble in water, also soluble in alcohol, but much less so than in water; its solution is dextrorotatory, but when quite freshly prepared its solution is lævorotatory, becoming dextrorotatory after about nine minutes. Rhamnose does not undergo alcoholic fementation. It reduces Fehling's solution and ammoniacal silver nitrate; on reduction with sodium amalgam it yields the corresponding alcohol (Rhamnite), $CH_3(CHOH)_4CH_2OH$; on oxidation with bromine water it yields the corresponding acid (Rhamnonic acid), $CH_3(CHOH)_4COOH$; on oxidation with nitric acid it yields oxalic acid and a trioxyglutaric acid, $COOH(CHOH)_3COOH$; silver oxide oxidises it to aldehyde and acetic acid. It forms a tetranitrate and a tetrabenzoate. Like dextrose, it forms an oxime with hydroxylamine, an osazone with phenylhydrazine, and a cyanhydrin with hydrocyanic acid. Rhamnose occurs in a state of combination in several glucosides, especially in quercitrin and in hesperidine. It is prepared from quercitrin by hydrolysis with dilute sulphuric acid; after filtering, the liquid is saturated with barium carbonate, again filtered, concentrated, and allowed to crystallise, when crude rhamnose separates. A further yield is got from the mother liquor by adding absolute alcohol. The crude crystals are purified by recrystallisation from water or alcohol.

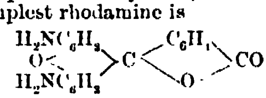
Rhea (*Botany*). A textile fibre known also as Ramie fibre or China grass, obtained from the stem of a Chinese nettle, *Boehmeria nivea* (order, *Urticaceæ*).

Rheostat (*Elect.*) An electric resistance which can be continuously varied within certain limits.

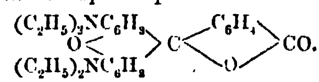
Rhizome (*Botany*). The stout underground stem ("rootstock") seen in the Iris, Solomon's Seal, and Wood Anemone. Its tissues are filled with various food materials, such as starch, etc.

Rhodamine. *See* DYES AND DYEING.

Rhodamines (*Chem.*) Dyes formed by the condensation of meta-amidophenol and its alkyl derivatives with phthalic and other anhydrides of dibasic acids, especially succinic acid. They are similarly constituted to the condensation product of resorcin and phthalic anhydride, FLUORESCEIN (*q.v.*); thus the simplest rhodamine is



The dye Rhodamine B is the hydrochloride of diethylmeta-amidophenolphthalein—



It forms green crystals, soluble in water and in alcohol; it dyes silk a strongly fluorescent bluish-red; cotton mordanted with tannin a violet red, not fluorescent unless the cotton has been oiled. It is prepared by heating diethylmeta-amidophenol with phthalic anhydride and concentrated sulphuric acid. The diethylmeta-amidophenol may be prepared from resorcin by heating it with ethylamine and ethylamine hydrochloride in aqueous solution under pressure at 200°. Other rhodamines are got by substituting succinic anhydride for phthalic anhydride.

Rhodium (*Chem.*) Rh. Atomic weight, 103. A rare metal resembling palladium and in a less degree platinum. It occurs in small quantity in platinum ores. It is white, and only fuses in the oxyhydrogen flame, and is in mass insoluble in acids. Occasionally used with platinum in making thermo-couples. It forms a chloride, $RhCl_3$, and oxides, RhO, Rh_2O_3, and RhO_2: it also forms complex ammonia compounds.

Rhodochroisite (*Min.*) Carbonate of Manganese, $MnCO_3$. Usually contains about 75 per cent. of carbonate of manganese, with other carbonates to 25 per cent., probably as replacement products. Rhombohedral, in curved rhombs of a flesh red colour. Also called DIALOGITE. From Oswestry in Shropshire, Warwickshire, co. Clare, Transylvania, Saxony, etc.

Rhodonite (*Min.*) Silicate of Manganese, $MnSiO_3$. Manganous oxide = 54·1, silica = 45·9. Triclinic; usually occurs massive. Colour, flesh red, changing to a black on exposure. It is used in glass and earthenware glazing to give violet tints. From Cornwall and Devon in England, Sweden, the Harz, Siberia, and several places in North America.

Rhomboid. A parallelogram whose adjacent sides are unequal and whose angles are not right angles.

Rhomb Spar (*Min.*) A ferruginous variety of DOLOMITE (*q.v.*)

Rhombus. A parallelogram whose sides are equal, but whose angles are not right angles.

Rhubarb. *Rheum officinale* (order, *Polygonaceæ*). The root, when dried, forms the medicinal rhubarb. It is imported from China. Several varieties are used, the best known being the Russian ("Turkey") Rhubarb. The garden forms are *R. rhaponticum* and *R. undulatum*.

Rhymer. A REAMER (*q.v.*)

Rhyolite (*Geol.*) An eruptive rock, in most cases a lava, of subacid or even acid composition, which is characterised by potash felspar crystals in a lithoidal ground mass. The rock often shows crumpled bands of alternately lighter and darker colours. The crumbling has arisen from the flowing movement of the rock after its solidification was far advanced.

Rhythm (*Music*). Consists of (1) proportionate duration of sounds, (2) symmetrical grouping, (3) regular accentuation. It signifies the arrangement by which the cadences are placed; hence a musical composition may be of two bar, four bar, five bar, or eight bar rhythm, and according as these cadences fall, so the composition is of REGULAR or IRREGULAR RHYTHM. Ernst Pauer says: "The rhythmical construction of a musical piece cannot be definitely fixed according to a pattern or an arbitrary rule. The law that has to be obeyed does not restrict freedom of fancy and feeling; *variety* is necessary as well as *unity*. Rhythm may be described as the art of the versifier, necessary, but yet only supplementary, to the genius of the poet or composer; for although rhythm will heighten the beauty of a melody, it can, even when used with the greatest cleverness, never succeed in ennobling vulgarity or triviality in music" (*Primer of Musical Forms*).

Rib (*Carp. and Join.*) One of the curved rafters of a roof or circular framing.

—— (*Eng.*) A projecting part, usually forming a ridge or flange, whose function is to strengthen the object across which it runs. In ships the ribs are the vertical portions of the framework.

—— (*Textile Manufac.*) A fabric differing from a rep in that the lines may be either across or lengthways of the fabric. It is a common type of worsted pattern.

Riband (*Her.*) A diminutive of the bend, of the same dimensions as a cotise but with the ends cut off or "couped," and not reaching the edges of the shield.

Rib and Panel Vault (*Architect.*) The form of vaulting which was introduced in England at the close of the Norman period, and which is one of the characteristics of Gothic architecture. The ribs are the constructional parts of the vault, the panels, cells, or severies being merely filled in between them. In this system of vaulting the thrusts are concentrated upon definite parts of the wall, which are designed to counteract them. In early rib and panel vaults the only ribs used were the formerets or wall ribs, the transverse ribs, and the diagonal ribs. In later work ridge ribs and tiercerons (intermediate ribs between the transverse and diagonal ribs) were introduced, and finally lierne ribs, which are merely decorative, were added. *See* SEXPARTITE VAULT, BARREL VAULT, FAN VAULT, BOSS, *and* LIERNE RIB.

Ribbon Brake (*Eng., etc.*) A BAND BRAKE (*q.v.*)

Ribbon Jasper. *See* AGATE.

Ribbon Saw (*Eng.*) A BAND SAW.

Rice (*Botany*). The grain of the Rice plant, *Oryza sativa* (order, *Gramineæ*), an annual grass grown under hot, moist conditions in tropical countries. Rice in the husk is termed "Paddy." Rice is remarkably deficient in proteids, fats, and salts. It is essentially a carbohydrate food, and is extremely digestible when well cooked. It should be steamed rather than boiled, otherwise it loses some of its very small quantity of proteid and salts.

Rich Lime (*Build.*) *See* FAT LIME.

Ricinoleic Acid (*Chem.*)

$CH_3(CH_2)_5 . CHOH . CH_2 . CH : CH . (CH_2)_7 . COOH.$

A soft crystalline solid; melts at 17°; soluble in alcohol and ether; dextrorotatory. With bromide it forms a dibromide. Heated with iodine and amorphous phosphorus it yields iodo-oleic acid, which yields stearic acid on reduction with zinc and hydrochloric acid. Nitrous acid converts it into the isomeric ricinolaidic acid. Fused with caustic soda it gives secondary octyl alcohol—

$$\begin{array}{l} CH_3 \\ | \\ CHOH \\ | \\ C_6H_{13} \end{array}$$

and sebacic acid, $(CH_2)_8(COOH)_2$. It occurs as its glyceryl ester in castor oil, of which the ester is the chief constituent. It is prepared by hydrolysing castor oil with caustic soda, and purifying the crude acid by crystallising the barium salt.

Riddle. A SIEVE.

Riddlings. Coarse material left in the sieve after sifting. The term is chiefly confined to the foundry.

Ridge (*Build.*) The upper angle of a roof.

—— (*Foundry*). A horizontal channel in the sand of a mould for leading metal to some definite point during pouring.

Ridge Board (*Build.*) The board to which the top ends of the rafters of a sloping roof are fixed.

Ridge Course (*Build.*) The course of slates or tiles next to the ridge of a roof.

Ridge Roll (*Build.*) A piece of wood of approximately circular section fixed along the top edge of the ridge board (*q.v.*)

Ridge Tiles (*Build.*) The ornamental tiles fixed on the ridge board of a roof.

Riding (*Eng.*) A belt is said to ride when it mounts on to the flange of a flanged pulley; a driving chain, when it mounts the cogs so that it rests on the tips of the teeth; two gear wheels, when they become displaced so that the tips of the teeth come in contact.

Riffler (*Eng., etc.*) A file whose axis or centre line is curved.

Rigger (*Eng.*) A name sometimes applied to a belt pulley.

Right Angle. *See* ANGLE.

Right Ascension (*Astron.*) The angular distance, measured along the equator between the First Point

of Aries and the declination circle of the star (*i.e.* the secondary great circle to the equator, which passes through the star). Commonly denoted by "R.A."

Right Handed Screw. A screw whose thread runs upward from left to right when viewed with the axis in a vertical position. If the screw be turned in its nut in a clockwise direction, it recedes from an observer looking along its axis. This is the common form of screw thread; the reverse or left-handed screw is only rarely used.

Right Line. A STRAIGHT LINE (*q.v.*)

Rigid Body. A rigid body is one in which no relative motion of the particles can be produced by the application of forces. No perfectly rigid body exists; but from the engineers' point of view the harder metals (*e.g.* cast iron) may usually be considered rigid.

Rigidity. In general terms the power possessed by a body of resisting changes of shape. The MODULUS OF RIGIDITY or COEFFICIENT OF RIGIDITY is often termed simply the RIGIDITY. It is the relation of the SHEARING STRESS to the SHEAR or SHEARING STRAIN. *See also* SHEAR

Rigore, Con; Rigoroso (*Music*). With exactness, strictness.

Rilles on the Moon (*Astron.*) Trenches with raised sides more or less steep.

Rimer (*Eng., etc.*) A REAMER (*q.v.*)

Rim Wheel (*Cotton Spinning*). The wheel on the headstock of a mule which transmits motion to the tin roller and spindles.

Rinforzando (*Music*). Abbreviated *rinf.*, *rf.*, or *rfz.* Reinforcing the power of a musical phrase. It is to a phrase what sforzando is to single sounds.

Ring (*Build.*) A brick arch consists of a number of half brick rings one above the other.

Ring Armatures (*Elect. Eng.*) *See* ARMATURES.

Ring Compounds (*Chem.*) Suppose a compound formed by joining to a given group two other groups or more than two; then if the last group joined up be connected with the first, we have what is called a ring compound. In practice rings are not formed in this way. An actual example is as follows:—glycerine has the formula—

$$\begin{array}{c} CH_2OH \\ | \\ CHOH \\ | \\ CH_2OH \end{array}$$

with bromine and phosphorus it forms allyl bromide—

$$\begin{array}{l} CH_2 \\ \| \\ CH \\ | \\ CH_2Br \end{array}$$

This compound unites with hydrobromic acid to form trimethylene bromide—

$$\begin{array}{l} CH_2Br \\ | \\ CH_2 \\ | \\ CH_2Br \end{array}$$

The latter, when acted on by sodium, forms trimethylene—

$$\begin{array}{c} CH_2 \\ H_2C \diagup\!\!—\!\!\diagdown CH_2 \end{array}$$

which is a ring compound. When the ring is made up by union of atoms of the same kind it is called an isocyclic ring; when the atoms are not all alike it is called a heterocyclic ring. Benzene and naphthalene are important examples of isocyclic ring compounds. Pyridine, Quinoline, Furfurane, Pyrazole, Pyrrole, the Lactones are important examples of heterocyclic ring compounds.

Ringelmann's Smoke Scale. A series of white cards about 8 in. square ruled at right angles into squares. They are graduated (by increasing the thickness of the lines) from all white to nearly black. The white spaces are cut out, and, by looking at "black" smoke through this screen, its degree of blackness can be gauged by the screen and the smoke appearing to be of the same shade. Solid ruled cards may also be merely compared with the smoke emitted and the shade judged.

Ring Frame (*Cotton Spinning*). A continuous spinning machine suitable for warp yarns up to fifty counts. It produces a thread less fibrous than the mule and rather rounder, but not so elastic, nor will it spin as soft a thread as the mule. For ordinary spinning it has greater productive powers per spindle than the mule, and may be attended to by a female. The drawing, twisting, and winding of thread on to bobbin are performed simultaneously, a small metallic ring called a traveller being used for the purpose. So far it has not been very successful in spinning weft yarns or fine counts.

Ring Micrometer (*Astron.*) A narrow metal ring attached to a thin piece of glass in the focal plane of an eyepiece. Used in conjunction with a telescope. *See* MICROMETER.

Rings of Saturn (*Astron.*) The planet Saturn is surrounded by a host of small satellites, which all lie in one plane, and constitute a series of rings about the planet's Equator.

Ring Traveller (*Cotton Spinning*). A small metallic ring which is connected to the thread, being spun on a ring frame, so as to impart twist and also assist in the winding of thread on to bobbin. *See* RING FRAME.

Ripidolite (*Min.*) One of the Chlorite Group of minerals now more often known as Clinochlore. It is a monosymmetric basic silicate of magnesium and aluminium, $5MgO \cdot Al_2O_3 \cdot 3SiO_2 \cdot 4H_2O$. Chiefly of interest as a rock forming mineral.

Ripieno (*Music*). Supplementary or filling up parts.

Ripper (*Build.*) A tool used by slaters for cutting the nails under the slates when removing them.

Ripping (*Carp.*) Cutting timber in the direction of the grain.

Ripple (*Phys.*) In general a small wave on the surface of a liquid. The term is confined in strictly scientific language to those waves which are propagated chiefly by the surface tension of the liquid in which they are produced.

Ripple Marks (*Geol.*) A waved surface left upon sand and similar deposits by a to and fro movement of either wind or water. The ripples are usually formed either directly at the surface or else beneath

a small depth of water; but their presence has been detected on a sandy floor of the sea at a depth of a hundred feet or more. Sand ripples are very characteristic of desert regions. Ripple marks occur commonly on the surface of deposits of volcanic dust.

Rippling (*Linen Manufac.*) When the flax plant is ripe, seed capsules form about the size of peas, and contain the flax seed or linseed. These are usually cleared off before the stalks are retted by drawing the plant through a coarse steel comb. The process is termed Rippling. *See* LINSEED OIL (*under* OILS).

Rip Saw (*Carp. and Join.*) A saw used for cutting timber in the direction of its fibres, and having about two and a half to three teeth to the inch.

Rise (*Build.*) The height of the crown of an arch above the springing. The height of a step, or of a roof above the wall plates. *See* ARCH.

—— (*Typog.*) The term was originally used when a forme could be lifted from the imposing surface without any of the types falling out. It is now used when, through faulty locking-up or bad justification, the forme "springs" and the spaces or furniture "rise" to the level of the type face.

Riser (*Build.*) The vertical part of a step. *See also* STAIRCASES.

—— (*Foundry*). An opening extending from the cavity of a mould up through the sand to the surface. When liquid metal is poured in through the gates the air in the mould rushes out of the risers, and, when the mould is full, liquid metal rises in them, showing that the mould is full. The risers also form a channel by which dirt, scoriæ, etc., can be swept out of the cavity by the rush of the molten metal, instead of accumulating in the top of the mould and rendering the upper part of the casting unsound.

Risers (*Typog.*) The material upon which stereo and electro plates are mounted and fixed to render them "type high."

Rising and Falling Saw (*Carp.*) A circular saw which can be caused to project above its table to a greater or less extent by raising or lowering the spindle, which is provided with mechanism for the purpose. It is used for cutting grooves of various depths.

Rising and Falling Table (*Eng.*) Certain machine tools (*e.g.* drills, milling machines) are sometimes fitted with a table of this kind, *i.e.* one which can be raised or lowered either by hand or automatically.

Rising and Setting (*Astron.*) The instant that a celestial body comes into or disappears from view, when the observer has a perfectly clear horizon.

Rising Gate (*Foundry*). A RISER (*q.v.*)

Rising Main. (1) The vertical water pipe in a building that issues from the main pipe. (2) The pipe that supplies a cistern, etc.

Risoluto (*Music*). With resolution.

Risvegliato (*Music*). In an animated manner.

Ritardando (*Music*). Gradually decreasing the speed. *Cf.* ACCELERANDO.

Ritenuto (*Music*). Slower, *i.e.* the whole passage so marked is *at once* to be taken slower, whereas ritardando means *gradually* decreasing the pace.

Rivers (*Geol.*) Solar energy elevates large quantities of vapour, and gravitation coming into play after the vapour is again condensed, the water of rivers is thereby set in motion, enabling them to perform a considerable amount of geological work. Most of it is of a mechanical nature, and consists, in the first instance, of the removal of part of the rock surface in contact with the moving water; but part of the effect produced arises from chemical causes. In the higher parts of river valleys the rate of erosion of the river bed in a vertical direction is usually in excess of that of the sides of the valley above the river bed. Hence, under the combined effect of lateral and vertical erosion, the sides of river valleys, in the hilly part of their track, are usually characterised by steep slopes. The chief function of rivers, regarded from a geological point of view, is as agents of transport. Rock material, disintegrated and decomposed by the action of sub-aërial forces, sooner or later finds its way into rivers, which transport the coarser materials to lower levels chiefly during floods, and constantly transfer the materials that are in suspension, as well as those that are held in solution, from the land to the sea, where these materials are eventually left in a more or less stratified form. *See* CLOUDS AND RAIN.

Rivet. A short cylindrical fastener of metal with a strong head at one end, used for forming a joint between overlapping plates, etc. The rivet is inserted in a hole which has been previously drilled or punched through the plates and is then "closed"; *i.e.* a second head is formed by hammering either in the cold or while the rivet is still hot from the rivet forge. Copper rivets are always closed in the cold; iron or steel ones are nearly always heated. The closing may be done by a machine worked by hydraulic or other power; the use of a machine is quicker, and does not involve the jarring of the plates which is produced by excessive hammering.

Riveted Joint (*Eng.*) Used in girders, boilers, etc. It is suitable for joints which have to stand a tangential or shearing force—that is, where the rivets have to resist forces which tend to move the plates past each other.

Riveted Stays (*Eng.*) Stays or tie rods whose ends are riveted over, *i.e.* heads are formed on them by hammering, as in the case of an ordinary rivet. This method of fastening a stay rod is usual in boilers; but the ends are often screwed into the holes first, and the rivet head formed on the projecting end of the screw.

Rivet Forge (*Eng.*) A small portable forge used for heating rivets.

Rivet Holes (*Eng.*) Drilled or punched holes passing right through plates which are to be riveted together. Drilled holes are much the better.

Riveting Machine (*Eng.*) A machine resembling a punching machine in action, but furnished with dies, one of which supports the head of a rivet, while the other closes up or forms a head on the other end. It is commonly worked by a hydraulic ram.

Rivet Steel. Mild steel of good quality is often used instead of wrought iron for rivets. It should have considerable tensile strength, and care must be taken to prevent overheating in the rivet forge, as if the steel become "burnt" it is practically useless.

Road Locomotive. A TRACTION ENGINE (*q.v.*)

Road Metal (*Civil Eng.*) Stone suitable for road making; it is crushed or broken to a suitable size by hand or machine

Roan (*Leather Manufac.*) Tanned sheepskin when dyed and finished is known as roan. Rough tanned basil, after scouring, straining, dyeing, and finishing, becomes a roan. It is largely used in the cheaper kinds of bookbinding, having somewhat the appearance of morocco, but is not nearly so durable.

Roasting (*Met.*) The preliminary heating of ores without fusion, whereby oxidation is effected, or certain constituents, such as sulphur, are partially driven off.

Robeson Magnets (*Elect.*) A magnet formed by a thin rod of steel, on the ends of which are fixed steel spheres. The poles of the magnet lie almost exactly at the centres of these spheres.

Rocaille. The name given to the style of art in vogue in the time of Louis XIV. A characteristic feature was the treatment of scrolls and foliage. *Cf.* ROCOCO.

Rocelline (*Chem.*) *See under* NAPHTHYLAMINES.

Rochelle Salt (*Chem.*) *See* TARTRATES.

Roches Moutonnées (*Geol.*) The surfaces over which a glacier has moved for any length of time has usually been moulded by the erosive action of the stone shod base of the ice into a more or less irregular form, with pits and mounds of various sizes and shapes, all smoothed and striated by glacial action. Where these rounded bosses of rock are exposed at the surface they look, at a distance, like scattered sheep. Hence the name.

Rock (*Chem. Tech.*) The solid mixture of stearates of lime obtained in the first stage of the manufacture of stearine.

—— (*Geol.*) The term "rock" in geological descriptions is not restricted to hard stone, such as granite or sandstone, etc., but is applied to any naturally formed deposit, whether hard or soft, which preserves a certain uniform character over a considerable distance. Thus a bed of soft mud or a bank of sand would come under this designation quite as much as a stratum of limestone or a bed of grit.

Rock Crystal (*Min.*) A variety of QUARTZ (*q.v.*)

Rocker (*Elect.*) The support of a brush in a dynamo or electric motor, by means of which the exact position of the brush can be adjusted.

—— (*Engrav.*) A tool somewhat resembling a broad chisel, used in mezzotint engraving for obtaining a series of points or grain on the plate. *See* MEZZOTINT (*under* ENGRAVING).

Rock Forming Minerals (*Geol.*) The chief rock forming minerals are silicates, the principal exceptions being Quartz, Calcite, and some iron ores. The silicates may be classed as follows: (1) Silicates of Alumina, and (*a*) Potash, (*b*) Soda, (*c*) Lime; (*d*) (*a*) and (*b*), or (*b*) and (*c*) respectively, in combination. To this category belong the Felspars and the Felspathoids. The felspars include: (*a*) The potash felspars Orthoclase and Microcline, the former being usually an original constituent of the acid eruptive rocks, and the latter a prominent mineral in the acid gneisses and pegmatites. (*b*) The soda felspar Albite, which is usually of secondary origin, and is not of common occurrence except in the druses of large granite masses. (*c*) The lime felspar Anorthite, which in its normal state is of very rare occurrence. (*d*) The soda lime felspar Oligoclase, which is a common constituent of many Diorite Granites, and of the Gneisses and Pegmatites allied in composition to them. (*e*) The lime soda felspar Labradorite, which, with its varieties, is probably the most widely distributed of all the felspars, and is the common felspar of the basic and of most of the sub-basic eruptive rocks. The Felspathoids include the minerals Leucite and Nepheline, of which the former is common in many post-cretaceous basalts. Allied to the felspars in composition is the light mica, Muscovite, which in many cases is formed out of dynamically metamorphosed potash felspar. This mica is practically indestructible when in small flakes, and hence is found in most sandstones and also in many clays. Some Muscovite is an original mineral of Granites and Elvans. (2) The Ferro-magnesian Silicates. These include (*a*) Olivine, which is a mineral of common occurrence in the basic and the ultrabasic rocks of eruptive origin, and is rare in, or absent entirely from, the gneisses and schists. (*b*) The Pyroxenes, of which there are several species, varying in crystalline characters, and, to a small extent, also in composition. The commonest of the Pyroxenes is Augite, which is present in most basic and ultra-basic eruptive rocks. A less common species is Enstatite, which also occurs in the rocks just mentioned. The minerals classed under (*a*) and (*b*) give rise, through the prolonged action of underground waters, to the important rock Serpentine (*q.v.*) Some Pyroxene is an important constituent in the initial stage of the Scottish Lewisian Gneiss. Another variety (Diopside) is a common secondary mineral in many highly metamorphosed marbles. Augite, under the influence of dynamic metamorphism, may pass into Hornblende. On the other hand, the latter mineral changes into the former under thermo-metamorphic action. (*c*) The Amphiboles. Of these there are many species, distinguished by their crystalline characters or by differences in chemical composition. The commonest is Hornblende, which is an essential constituent of all Diorites, and which occurs also in most Syenites, as well as in the Diorite-Granites. It is a common constituent in most Andesites and Porphyrites (*q.v.*), as well as the majority of Trachytes and Lamprophyres. Hornblende enters largely into the composition of most of the Scottish Lewisian Gneisses, seemingly as a secondary mineral due to the alteration of the original Pyroxene, and is also of common occurrence in the Pegmatites of these Gneisses. Under prolonged dynamic action Hornblende passes into Biotite, so that many Biotite Gneisses were originally Hornblende rocks. Of the remaining Amphiboles the only one that calls for remark is Tremolite, which is a product of the thermo-metamorphism of some magnesian limestones. Biotite, however, is often an original mineral, and is a characteristic mineral of nearly all Granites, Syenites, and Diorites, as well as of their respective gneisses and pegmatites. It is also found in most Trachytes and Andesites, as well as in the Lamprophyres and Porphyrites. Quartz is an essential constituent of the acid eruptive rocks, and of their respective pegmatites and gneisses. In its derivative state it forms sands and sandstones, and is then a characteristic mineral of the terrigenous rocks (*q.v.*) Calcite is the basis of all limestones. Ilmenite (the ferrous titanate) is the chief *original* iron ore of the basic and ultrabasic eruptive rocks.

Rocking Frame (*Eng.*) A hinged or pivoted support for a train of gear wheels, used for actuating the back shaft of a self acting lathe (*q.v.*)

Rock Salt (*Geol.*) Commercial Salt is obtained from three principal sources: (1) By the natural or the artificial evaporation of sea water; (2) by collecting the films of salt left on the surface of deltas where river water is subject to excessive evaporation; and (3) from stratified deposits, such as those which occur in connection with the Keuper Marl (Cheshire), or with the Bunter Marl (Middlesboro'). The term Rock Salt is generally restricted to these last-mentioned stratified deposits. Most Rock Salt appears to have originated in the following manner: During storms large quantities of the spray of sea water are driven inland by the winds, and, in course of time, undergo some desiccation. Hence the atmosphere, more especially in maritime districts, may be said to be loaded with minute particles of salt dust. These salt particles eventually form the nuclei of raindrops, or fog particles, or flakes of snow, and are thus conveyed to the surface of the Earth. Sooner or later the water thus originating finds its way into rivers, and thence, in the ordinary course, back again to the sea, where the cycle commences anew. But in many parts of the world the water of even large rivers may be entirely returned to the clouds by excessive evaporation. The Caspian, the Dead Sea, the Great Salt Lake, the desert region of Central Asia, present good examples of this nature. In all of these the salts carried down in solution by the rivers undergo concentration as evaporation proceeds, and the dissolved matters are eventually left behind in the solid form. As most of the British Salt deposits occur in connection with strata which have certainly been formed under arid conditions, it is natural to conclude that the deposits of Rock Salt which they enclose have been formed by the prolonged evaporation of bodies of river water in a manner similar to that referred to above.

—— (*Min.*) Sodium Chloride; NaCl. Sodium = 39·3, chlorine = 60·7 per cent. Cubic, sometimes in skeleton cubes or hopper shaped crystals; more often massive. Colourless to yellow, red, blue, or purple, the colours being due to impurities. Magnesium and calcium chlorides are usually present as impurities, and cause the salt to be deliquescent. The sulphates of calcium and magnesium are other common impurities. Large deposits of salt occur around Nantwich, in Cheshire; at Droitwich, in Gloucestershire; also in Catalonia and Castile, in Spain; Bex, in Switzerland; and numerous other localities.

Rococo. A debased style of ornament of the times of Louis XIV. and XV. It is an exaggerated style of ROCAILLE (*q.v.*), characterised by confused and meaningless scrolls, shellwork, and foliage. Subsequently the term was used contemptuously to denote heavy and tasteless decoration. *See also* RENAISSANCE (*Architect.*)

Rod (*Build.*) Brickwork (in London) is measured by the rod, which equals 272¼ square feet of reduced work, *i.e.* one brick and a half thick. In practice the ¼ foot is generally ignored, making it 272 square feet.

—— (*Carp. and Join.*) (1) A stick used for measuring. (2) A flat board, carefully planed, on which is constructed a full sized drawing of a piece of work; in most cases the cross section of the work under construction forms the principal drawing, other details being added if necessary. The joiner uses the rod as a working drawing, taking his measurements from it, and also checking the dimensions of the different pieces of the work by direct comparison with those shown on the rod.

Rod Chisel (*Eng.*) A blacksmith's cutting chisel, held by means of a long handle usually consisting of willow twigs or withies.

Rodding (*Foundry*). Supporting the sand forming the upper part of a mould which projects into a cavity by means of rods of iron of suitable length suspended from the flask. This also prevents the projecting sand from being broken away by the fluid metal.

Rodinal (*Photo.*) *See* PARA-AMIDOPHENOL.

Rod, Pole, *or* **Perch.** *See* WEIGHTS AND MEASURES.

Roentgen Rays (*Elect.*) *See* RADIATION.

Rohrflöte (*Music*). A reedy flute. An organ stop of closed pipes, with a hole in the stopper.

Roll (*Plumb.*) A rounded piece of wood used to dress the lead over at the joints on a gutter or flat.

Rolled Bars (*Met.*) Bars of iron or steel of uniform section produced by passing them through a rolling mill.

Rolled Beam, Girder, *etc.* (*Eng.*) Beams or girders made in one piece by rolling mills, instead of being built up of separate parts.

Roller (*Engrav.*) A wooden cylinder covered with leather, used for spreading an acid resisting varnish over the plane surface of a plate that has to be rebitten. *See* ENGRAVING AND ETCHING.

—— (*Music*). A part of the mechanism of an organ. *See* p. 439.

Roller Chain (*Cycles*). *See* CYCLES.

Roller Delivery Motion (*Cotton Spinning*). A motion on a mule for giving out two or three extra inches of yarn during the winding process as the carriage travels inwards.

Roller Feed (*Carp., etc.*) Certain forms of wood working machinery have grooved rollers between which the timber passes. The rotation of these rollers feeds or drives the wood towards the saw or cutter.

Rollers (*Typog.*) Used for inking the forme in the course of printing. They are made of a composition consisting of glue, treacle, glycerine, etc.

Rolling (*Eng.*) The production of bars or plates by the ROLLING MILL (*q.v.*)

Rolling Curves. Pieces of thin wood, metal, card, etc., cut to shape, are used for setting out the teeth of wheels. *See* WHEEL TEETH.

Rolling Friction. The friction between a rotating body and the surface with which it is in contact, when there is no relative movement of the two surfaces at the point of contact. The case of a wheel rolling on a smooth surface is the best example; the friction is much less than the SLIDING FRICTION (*q.v.*)

Rolling Load (*Eng.*) A load or weight which moves along a structure, as in the case of a vehicle passing over a bridge.

Rolling Locker (*Lace Manufac.*) (1) A plain net machine (Heathcote's principle), but the bottoms of the carriages are toothed, and the teeth engage with fluted rollers, which contribute the necessary movement to the carriages. (2) Defines the method of moving the carriages in the description of lace machine bearing that prefix.

Rolling Mills (*Met.*) Sets of iron (or steel) rollers geared together so as to rotate in opposite directions. Bars and plates of iron are formed by passing a mass of iron between the rollers, which are either plain (for plates) or furnished with suitable grooves for the production of bars of any required section. The machinery can be reversed in some cases, so that a bar can be passed through from the opposite side, in order to save the time and labour involved in bringing the metal round to the side from which it was first passed through. The same object is served by having three rollers, when the mill is said to be THREE HIGH, as distinguished from the mill with two rollers, which is termed TWO HIGH. In the three high mill the top and bottom rollers turn in the same direction, the centre one in the opposite direction. The bar is first passed between the lower ones, then passed back between the upper ones (or *vice versâ*). There are three classes of Rolls; PUDDLING ROLLS, which consist of a train of two pairs for blooms, and are often called the Forge Train; MILL ROLLS, which produce finished merchant iron from billets, and are generally three high rolls; and PLATE MILL ROLLS, specially intended for rolling boiler and other plates. Sheet mills are similar, but for lighter work.

Roll Moulding (*Architect.*) (1) A round moulding or bowtell (*q.v.*) (2) A round moulding with a slightly projecting fillet. (3) A moulding formed of two half rounds, the upper one projecting slightly in front of the lower. The last form is more commonly known as a scroll moulding (*q.v.*), and is characteristic of Decorated Gothic architecture. A roll moulding with a well defined fillet is known as a "roll and fillet" moulding.

Rolls (*Bind.*) Tools used in finishing. A roll consists of a small brass wheel fixed to a handle, the periphery of the wheel being engraved with some design.

—— (*Met.*) *See* ROLLING MILLS.

Roman (*Typog.*) The ordinary upright letter used in printing, as distinguished from *italic* and fancy type. Numerals expressed by letters as distinguished from those expressed by Arabic characters. *See* NUMERALS.

Roman Architecture. The style of architecture which obtained in the Roman Empire during the first four centuries of the Christian era. In this style the trabeated construction of the Greeks is combined with the use of the semicircular arch, dome, and vault. The three orders used by the Greeks were adopted, with various modifications, by the Romans; and variations of the Doric and Corinthian orders, known as the Tuscan and Composite orders respectively, were also used by them. The orders are, however, used more as a decoration than as an essential part of the construction. Pedestals are used to increase the height of the order, and the various orders are superimposed over each other, the simplest and most sturdy being always placed below the slender and more ornate orders. The peripteral form of temple of the Greeks was not extensively used by the Romans, the pseudo peripteral taking its place. Roman mouldings are usually richly carved, but they lack the refinement characteristic of Greek work. *See* GREEK ARCHITECTURE *and* ARCHITECTURE, ORDERS OF.

Roman Cement. A quick setting cement used for plastering the outside of walls, when required to be painted soon after the plastering is finished. *See* CEMENTS.

Roman Corinthian Order. *See* ARCHITECTURE, ORDERS OF.

Roman Doric Order. *See* ARCHITECTURE, ORDERS OF.

Romanesque Architecture. The architecture of Western Europe, which was developed after the decline of Roman architecture, and from which Gothic architecture was developed, is known as Romanesque. Romanesque architecture in England is divided into two periods—Anglo-Saxon and Norman (*q.v.*)

Roman Ionic Order. *See* ARCHITECTURE, ORDERS OF.

Röntgen Rays (*Phys.*) *See* RADIATION AND RADIO-ACTIVITY.

Rood. *See* WEIGHTS AND MEASURES.

Rood Screen (*Architect.*) The screen separating the chancel from the nave in a Gothic church. The platform which is frequently found above the rood screen, and known as the rood loft or jubé (*q.v.*), supported the rood or crucifix.

Roof (*Mining*). The upper or overhead surface of a working.

Roofs (*Build.*) Roofs vary greatly, both in form and in the materials employed in their construction. In countries where there is little rainfall, flat or very low pitched roofs are often found, and projecting eaves are added to afford shade. With increasing rainfall and the occurrence of snow the angle of inclination increases. The nature of the covering material varies with locality, climate, means of transit, the dimensions of the structure, and other factors. Among the chief natural materials now used may be enumerated THATCH in various forms, WOOD, SLATES, and STONE, which possesses a marked parallel cleavage; among manufactured materials, TILES, SHEET IRON, LEAD and ZINC, GLASS, and flexible materials which have been rendered waterproof, such as FELT, CANVAS, PAPER, CARDBOARD, and various patented materials. The structure which supports the roofing material takes many forms, of which a few only can be dealt with here The simplest form is the LEAN-TO ROOF (fig. 1). A is a RAFTER supported by WALL PLATES B and C, the former resting directly on the top of one wall, the latter being carried on corbels or by a ledge or offset. This form is suitable for spans of 8 or 10 ft. Fig. 2 shows a simple Couple Roof for spans of 10 or 12 ft.; the rafters A, A rest on wall plates B, B at their lower ends, and abut against a RIDGE PIECE D at the top. If the span exceed 12 ft., the outward thrust of the rafters may be counteracted by a tie or COLLAR E (fig. 3). When the tie extends across between the lower extremities of the rafters, the arrangement is termed a COUPLE CLOSE. The ties may serve to support

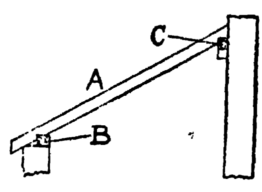


FIG. 1.

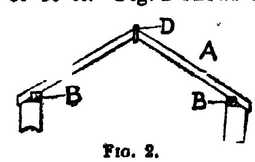

FIG. 2.

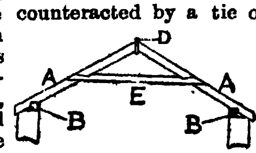

FIG. 3.

a ceiling, *i.e.* they form CEILING JOISTS. A roof of this pattern may be used for spans up to 16 ft. A further modification is shown in fig. 4. Here the rafters A, A rest on POLE PLATES F, supported by the TIE BEAM G. The rafters are further supported by STRUTS H, H, which abut against a piece K, termed a STRAINING SILL. For spans of 20 ft. or more a KING POST TRUSS (fig. 5) may be used. The

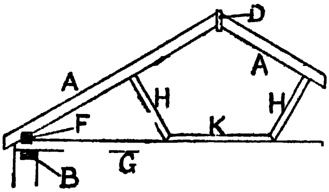

FIG. 4.

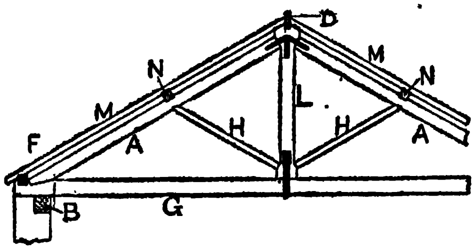

FIG. 5.

PRINCIPAL RAFTERS A, A are attached at their lower ends to the TIE BEAM G, the joint being secured if necessary by an iron strap passing round both rafter and tie beam. At the upper end each rafter is tenoned into the vertical KING POST. Iron plates, shown in black, strengthen these joints; at the lower end a strap passes under the tie beam, and is tightened up by wedges, forming a gib and cottar, and passing through the king post. The COMMON RAFTERS M, M are supported by PURLINS N, N, which are horizontal timbers placed parallel to the ridge and supported in turn by the principal rafters. In the construction of still larger wooden roofs a QUEEN POST TRUSS (fig. 6) is used.

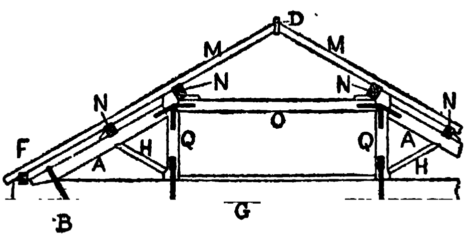

FIG. 6.

The letters correspond to those employed in fig. 5, with the addition of certain members; these are two QUEEN POSTS Q, Q; a STRAINING BEAM O; a straining sill between the lower extremities of the queen posts, and struts H, H. Iron bands and plates (shown in black) are used to strengthen the principal joints. The form of a roof may be modified to enable the roof space to be utilised as a room: one of the ways of doing this is to employ a MANSARD ROOF, shown in outline in fig. 7.

When two roofs intersect, as when the surface slopes upward from the ends as well as the sides (instead of ending in a gable), a HIPPED ROOF is formed. The rafter which runs from the intersection of the wall plates to the ridge is termed a HIP RAFTER; those which run from the wall plate and terminate against the hip rafter are termed JACK RAFTERS. A special device is often used in the larger roofs to strengthen the roof at the angles of the wall; this is shown in fig. 8. B, B are two wall plates, halved together at the angle, and connected by a member D. To the centre of this the DRAGON BEAM C is attached by a tusk tenon; at its other end it is notched to the wall-plates. In certain cases, such as churches and large mediæval halls, no ceiling is used, and the timbers of the roof are treated in a decorative manner. In such cases the HAMMER BEAM TRUSS is frequently used, the principal rafters being supported as in fig. 9. A corbel C supports a WALL PIECE W, from the top of which projects a HAMMER BEAM H, supported by a strut S. Above the hammer beam springs the PRINCIPAL RAFTER A. The hammer beam thus appears to be the end of a tie beam, of which the central portion has been removed. The largest roofs are now constructed of iron, which offers many advantages. A good tension joint, always difficult in woodwork, can easily be secured; tie beams may be replaced by slender tie rods, and struts, principals, etc., by rolled T iron or channel iron, much less cumbersome than the massive wooden members which they replace. Great variety of form is given to iron roofs, two simple forms being shown in figs. 9 and 10. Joints are made by flat plates, eyes, etc., riveted, or, preferably, bolted together.

FIG. 7.

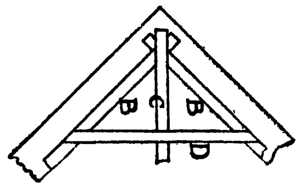

FIG. 8.

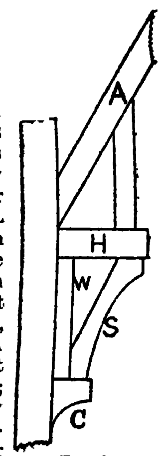

FIG. 9.

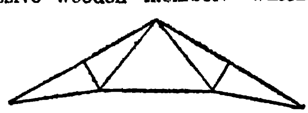

FIG. 10.

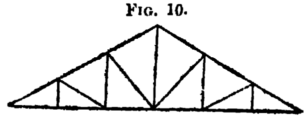

FIG. 11.

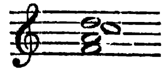
Root (*Music*). The note on which a chord is built, *i.e.* the bass note of a chord in its original position. The "Day" Theory traces all chords to the three roots, Tonic, Dominant, and Supertonic; but this theory is by no means universally accepted. For instance, the chord



in the key of C would, according to the "Day" Theory, have the root G, and be called the third inversion of the Dominant 11th. Another theorist looks upon F as the root, and speaks of it as the Added 6th; whilst yet another looks upon D as the root, and calls it the first inversion of a 7th. The idea of tracing chords from roots seems to have originated with Rameau in the latter part of the seventeenth century.

Rope Crane (*Eng.*) A form of overhead crane driven by ROPE GEARING (*q.v.*)

Rope Gearing (*Eng.*) Power can be transmitted long distances by means of ropes, which serve as belting. The ropes are allowed to hang somewhat loosely, and as the tension in them is small, they must run at a high speed. If the machinery to which the power is transmitted is not stationary, some arrangements must be made for "taking up the slack." This is usually managed by leading the rope over guide pulleys, which can be moved up or down as required, so that the necessary tension is maintained.

Ropes. Ropes are made of hemp, manilla, cotton, or iron or steel wire. The size of a rope is its circumference in inches; thus a six inch rope is one rather under 2 in. in diameter.

Rope Wheel. A pulley with a V-shaped groove, often with corrugations along the inside of the channel, which is used when motion has to be transmitted from the rope to the wheel, or *vice versâ.*

Rosaceæ (*Botany*). A large and important order of *Dicotyledons.* Many of the plants are of economic value (Rose, Apple, Plum, etc.), while others are cultivated as garden plants (Rose, Spiræa, Geum, etc.)

Rosalia (*Music*). The device of repeating a musical figure, transposing it one note higher at each repetition. This device should never be continued more than three times in succession.

Rosaniline (*Chem.*)

$$HC \begin{cases} \overset{(1)}{-} C_6H_3 \begin{cases} CH_3(3) \\ NH_2(4) \end{cases} \\ \overset{(1)}{-} C_6H_4NH_2(4) \\ \overset{(1)}{-} C_6H_4NH_2(4) \end{cases}$$

Leucaniline, the leuco compound of rosaniline. (Paratriamidodiphenylmetatolyl methane.)

$$HO.C \begin{cases} C_6H_3CH_3NH_2 \\ C_6H_4NH_2 \\ C_6H_4NH_2 \end{cases}$$

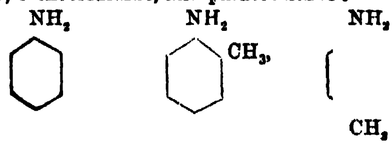
Colour base of rosaniline (Paratriamidodiphenylmetalolyl carbinol.)

$$C \begin{cases} C_6H_3CH_3NH_2 \\ C_6H_4NH_2 \\ C_6H_4.NH_2Cl \end{cases}$$

Rosaniline hydrochloride, commonly called rosaniline. Rosaniline itself would be

$$C \begin{cases} C_6H_3CH_3NH_2 \\ C_6H_4NH_2 \\ C_6H_4:NH \end{cases}$$

and is only known in the form of its salts, of which the hydrochloride and acetate too are used as a dye under the names rosaniline, magenta, and fuchsine. These salts form lustrous greenish octahedral crystals, slightly soluble in cold water, readily soluble in hot water or in alcohol, the acetate being more soluble than the hydrochloride. The solution is red. On adding much hydrochloric acid to the solution it turns yellow, owing to the formation of an acid salt. It dyes silk and wool bluish red, cotton mordanted with tannin and tartar emetic the same. When boiled with caustic soda solution the colour base is formed, and crystallises in white leaflets on cooling. Magenta forms a colourless compound with sulphurous acid, which gives other dyes when aldehydes are added to it (Test for aldehydes). The constitution is settled in the same way as that of Pararosaniline (*q.v.*) Rosaniline is prepared by the oxidation of a mixture in molecular proportions of aniline, orthotoluidine, and paratoluidine:



The oxidising agent is nitrobenzene in presence of iron and hydrochloric acid, and its mode of action is that described under pararosaniline (*q.v.*) That the nitrobenzene does not act directly seems to be shown by the fact that if chlornitrobenzene is used, no chlorine substituted rosaniline is formed. The action is carried out as under pararosaniline. A number of important dyes are rosaniline derivatives. *Acid magenta* is the sodium salt of rosaniline trisulphonic acid. *Hoffmann's violet* is triethylrosaniline, obtained by heating rosaniline, ethyl iodide, and alcohol together. *Iodine green* is pentamethylrosaniline, obtained by heating rosaniline, methyl iodide, and methyl alcohol together. *Aniline blue:* When phenyl groups are introduced into the rosaniline molecule the colour varies from violet to blue as the number of groups introduced increases from one to three. Aniline blue itself is triphenylrosaniline, one phenyl group entering each amido group. It is usually met with as the hydrochloride which forms brilliant green crystals insoluble in water, sparingly soluble in alcohol; the acetate readily dissolves in alcohol (spirit soluble blue). By the action of concentrated sulphuric acid one to four sulphonic acid groups may be introduced forming soluble aniline blues, which are much used as dyes. Aniline blue is made by heating rosaniline (colour base) with a large excess of aniline and some benzoic acid to the boiling point of aniline for some hours. On treating the product with concentrated hydrochloric acid the hydrochloride separates out.

Rose (*Botany*). *Rosa,* a genus of the order *Rosaceæ.* From *R. centifolia* is obtained the volatile oil known under the name of ATTAR or OTTO OF ROSES. This oil occurs in the petals of the flower. ROSEWATER is also prepared from the petals.

—— *or* **Rosette** (*Architect.*) The flower used in the centre of each of the concave faces of the Abacus of the Corinthian capital is known as a rose. A form of rose is also used as a repeating ornament in the Norman "Rose moulding," and the "Tudor rose" is an ornament freely used in Perpendicular Gothic architecture.

Rose Bengale. *See* DYES AND DYEING.

Rose Bit. A boring tool or bit whose shank or body is equal in diameter to the hole to be drilled, the cutting edges being formed on the end of the tool only. These cutting edges are usually in the form of radial teeth cut on the flat or rounded end of the bit. It is used for making a hole truly cylindrical after it has been drilled out nearly to size by an ordinary drill.

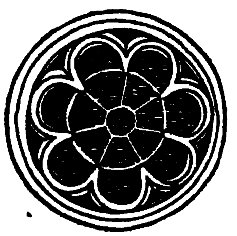
Rose Madder (*Paint.*) One of the lightest coloured of the madder lakes, but a little darker than pink madder. It is prepared from madder root and placed in a filter press, from which a clear liquor is obtained. On the addition (which should be gradual) of sodium carbonate, the colour is precipitated. *See* MADDER. Much of the commercial rose madder is made from alizarin. *See* LAKES.

Rosemary (*Botany*). The essential oil distilled from the inflorescence *Rosmarinus officinalis* (order, *Labiatæ*).

Rose Quartz (*Min.*) A variety of QUARTZ (*q.v.*) of a rose colour.

Rosette Copper (*Met.*) Copper obtained in thin masses by throwing cold water on the surface of the fluid metal.

Rose Window (*Architect.*) The richly traceried circular windows peculiar to the Decorated period of Gothic architecture are known as Rose Windows. These windows were developed from the wheel windows of the Early English period, in which the arrangement of the mullions resembles that of the spokes in a wheel. Rose windows are also known as Catherine wheel windows and Marigold windows.



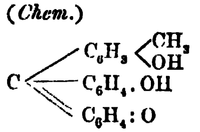
ROSE WINDOW.

Rosewood. *See* WOODS.

Rosin. *See* RESIN.

Rosin Oil (*Dec., etc.*) A heavy oil obtained by the dry distillation of rosin. It is mixed with lime for producing rosin greases, and used in printer's ink and sometimes as a paint oil. It is, however, not suitable for the latter purpose, as although it hardens when first exposed, it is very apt to afterward become soft. Three qualities of rosin oil are recognised, *viz.* "hard," "medium," and "soft." Specific gravity varies from 0·980 to 0·990, but heavier oils are made.

Rosolic Acid (*Chem.*)



Crystallises in red plates with green reflex; very slightly soluble in water; soluble in alcohol with orange-red colour; soluble in alkalis with red colour. It gives a leuco-compound on reduction. Heated with water at 240°, it forms phenol and dihydroxyphenyltolylketone, $C_6H_4OH.CO.C_6H_3CH_3OH$. It is formed from rosaniline (*q.v.*) by diazotising it and boiling the hexazo-compound with water; it is also formed by heating together phenol, cresol, arsenic acid, and sulphuric acid. A similar compound, called PARAROSOLIC ACID, or Aurin, is obtained in a similar way from pararosaniline. These compounds are only used in colouring varnishes and lacquers.

Rostrum (*Architect.*) A platform or other elevated place from which a speaker addresses an audience.

Rot. *See* WOODS.

Rotary Converter (*Elect. Eng.*) A machine by which a continuous current is changed into an alternating one, or *vice versâ*; both currents traverse the same armature winding. It is essentially an ordinary continuous current machine, but is provided, in addition to a commutator, with slip rings connected to definite points on the winding.

Rotary Cutter (*Carp.*) A number of separate cutters analogous to plane irons, mounted in a central block (termed an ADZE BLOCK) which rotates at a high speed; used for planing, moulding, etc., on a large scale.

—— (*Eng.*) A rapidly revolving wheel of hardened and tempered steel, furnished with teeth of suitable form; used in milling machines, gear cutting, etc.

Rotary Engines (*Eng.*) In many of the early forms of steam engine the chief moving parts had rotary, instead of reciprocating, motion. None of these forms were really successful, but their objects have now been attained in the STEAM TURBINE (*q.v.*), which, however, depends upon principles different from those of the early rotary engines. *See also* STEAM ENGINE.

Rotary Furnace (*Met.*) *See* REVOLVING FURNACE *and* PERNOT'S FURNACE.

Rotary-Machine. *See* TYPOGRAPHY.

Rotary Pumps (*Eng.*) CENTRIFUGAL PUMPS (*q.v.*)

Rotary Strainer (*Paper Manufac.*) An apparatus used for removing small knotty pieces of material from beaten pulp.

Rotary Transformer (*Elect. Eng.*) *See* ROTARY CONVERTER.

Rotation (*Astron.*) The motion of a body round a central axis, like the earth round its axis.

Rotation of the Plane of Polarisation (*Light*). *See* POLARISATION.

Rotator (*Met.*) A REVOLVING FURNACE (*q.v.*)

Rotatory Power (*Chem.*) *See* MOLECULAR ROTATORY POWER.

Rotor (*Elect.*) The revolving portion of an alternating or polyphase current motor.

Rottenstone (*Geol.*) Certain limestones contain a large proportion of silica, originally opaline in character, and mostly of organic origin. When such limestones are acted upon by waters containing carbonic acid or the humus acids, the lime is removed and the finely divided silica is left as a powder known as Rottenstone. Used for polishing household articles of metal.

Rotunda (*Architect.*) A building which is circular in plan, both inside and outside. The Pantheon at Rome and the Albert Hall in London are examples.

Rouge. A finely ground polishing powder of red colour, composed of ferric oxide, usually prepared from one of the salts of iron (*e.g.* the sulphate or oxalate). The term Rouge is also applied to various mixtures which are used as polishing powders and possess the same tint; *e.g.* a mixture of powdered TALC (*q.v.*) with the flowers of the SAFFLOWER (*q.v.*)

Rough Brackets (*Carp. and Join.*) (1) The wood brackets behind a plaster cornice. (2) The triangular pieces fixed to the carriages of stairs.

Rough Cast (*Build.*) A style of plastering the outside of half timber houses, gravel being mixed with or thrown on the wet plaster, to which it adheres.

Rough Coat (*Foundry*). The first layer of loam applied to a core bar, etc., in building up a core or a loam pattern.

Rough Cut (*Eng.*) (1) Applied to the coarsest toothed files. (2) Taking off a quantity of material to bring it approximately to shape or to remove skin or scale from the surface.

Roughing (*Linen Manufac.*) The first process of hackling. It consists of drawing the rough flax in handfuls over coarse pins set in a block of wood, to comb out all short and twisted fibres and split up all parcels of fibres that may be sticking together. Also termed "Rough hackling."

Roughing Hole (*Met.*) A basin-shaped cavity in the ground into which the slag from a blast furnace is run and allowed to cool before removing to the cinder tip. It is used as an alternative to cinder tubs. A conical steel pin is placed in the middle of the hole, by which to pick up the slag "oyster" when cool.

Roughing Out (*Eng.*) Shaping a piece of material in an approximate manner: applied especially to the preliminary stages in forging.

Roughing Rolls (*Eng.*) A rolling mill used to shape a bloom of puddled iron into a bar preparatory to the exact rolling which produces the final form. *See* ROLLING MILLS.

Rough Measurements (*Eng., etc.*) Approximate measurements given in the case of castings, forgings, etc. They are always larger than the proper dimensions of the finished object, thus allowing for machining and fitting.

Rough Plate (*Glass Manufac.*) *See* PLATE GLASS.

Roulette (*Engrav.*) A tool consisting of a small wheel or disc of tempered steel attached to a handle, the edge of the disc being furnished with sharp teeth. Used in engraving for imparting tone or tint to a metal plate, or as an adjunct in etching.

—— (*Math.*) A plane curve traced out by a point in a curve, or in the plane surface enclosed by the curve, which rolls (without slipping) on another curve.

Round (*Music*). A species of infinite canon in which the performers begin at regular intervals and sing the same music, coming "round" to the beginning again after reaching the end. A round written out in full instead of in score was called a "catch," but the term is also applied to a round having humorous effects, a well known example being, "Would you know my Celia's charms?"

Roundel (*Her.*) *See* ROUNDLET.

Rounding (*Bind.*) Shaping the back of a book previous to backing and binding. This is effected by holding the book in a certain position and striking the back with a hammer, the book being turned over from time to time until the back is a suitable shape.

—— (*Leather Manufac.*) Hides either previous to tanning or after tanning and before finishing are cut up into the butt or back, the shoulder, and the belly. This process is termed rounding.

Roundlet *or* **Roundel** (*Her.*) Small round discs of frequent occurrence as charges. The various tinctures give them distinctive names. If *or*, they are blazoned "bezants"; *argent*, "plates"; *azure*, "heurtes"; *gules*, "Torteaux"; *vert*, "pommes"; *purpure*, "Golpes"; *sable*, "pellets"; *tenné*, "oranges"; *sanguine*, "guzes." The last two are seldom seen. The Fountain is represented divided horizontally by wavy lines, *i.e.* barry wavy of six, argent and azure.

Round Nose (*Eng., etc.*) A term applied to various tools with a cutting edge which is rounded, as seen on plan.

Round Plane (*Carp.*) *See* HOLLOWS *and* ROUNDS.

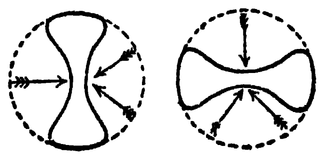
Router (*Carp.*) A cutting tool fixed in a stock or body; the edge projects some distance below the sole or lower surface of the stock, and is used for cutting the bottoms of grooves and sunk surfaces in woodwork.

Rove *or* **Roving** (*Textile Manufac.*) The term applied to the sliver or flat tape after it is finally drawn out and has received a slight twist in the machine called the roving frame, preparatory to spinning.

—— (*Cotton Spinning*). The final strand or coarse thread, slightly twisted, which is produced on the roving frame for the purpose of spinning into a thread on the ring frame or mule. Sometimes applied as a general term to the productions of all fly frames.

Rowel (*Her.*) The end of a spur formed like a star or wheel; replaced the earlier "pryck spur" about 1320.

Row Tube. This is a patented form of steam heating tube, which, when formed into coils or batteries, gives much better results than plain copper tubing. They are also used for condensing waste steam. An ordinary copper tube is indented alternately at the sides and top and bottom to yield the following section:



1 2

The steam is thus baffled, and a much greater heating or cooling surface rendered serviceable.

Royal (*Paper Trade*) Printing paper 20 × 25 in. Writing paper 19 × 24 in.

Royal Academy. *See* ACADEMY, ROYAL.

Royal Cord (*Silk Manufac.*) *See* OTTOMAN.

Ru (*Chem.*) The symbol of RUTHENIUM (*q.v.*)

Rubato (*Music*). Robbed. In order to enhance the expression of a passage some notes of a bar are performed not in strict time, *i.e.* if part of a bar is faster than the correct *tempo*, the remainder of the bar must be slower, as the length of the whole bar must correspond with other bars. Mr. Fuller Maitland says, in *The Dictionary of Music and Musicians*: "Tempo rubato is allowable in the works of all the modern 'romantic' masters, from Weber downwards, with the exception of Mendelssohn. In the case of the older masters it is entirely and unconditionally inadmissible, and it may be doubted whether it should be introduced in Beethoven."

Rubber (*Build.*) *See* CUTTER.

—— (*Joinery, etc.*) An abrading surface, such as sandpaper, wrapped round or attached to a block of wood, which serves as a holder. Used for smoothing wood ready for varnishing, polishing, etc.

Rubber (Indiarubber *or* **Caoutchouc).** An elastic gum or resin derived from a great variety of trees, vines, and shrubs, most of which grow in the Torrid Zone. The *latex* or milk is obtained by making incisions through the bark, but not as far as the wood. In the case of some vines and shrubs short lengths are chopped up and the rubber extracted by means of pounding and soaking in hot water. There are over two hundred varieties of rubber on the market—not because of any great difference in the rubber, as rubber, but owing to the method of preparation, impurities present, geographical and botanical distinctions. The valley of the Amazon, consisting of hundreds of thousands of square miles of forests in Brazil, Bolivia, and Peru, produces annually about thirty thousand tons of rubber, which is known as PARA (the name being derived from the city of Para, from which the bulk of it was originally exported). This rubber is derived from the *Hevea brasiliensis*. South America also produces other sorts of rubber, from the *Castilloa elastica*, which is known as CENTRALS; and from the Atlantic States of Brazil are obtained grades of rubber known as CEARA, PERNAMBUCO, MANGABEIRA. Africa comes next to South America as a rubber producing country, and the bulk of the rubber produced is from the *Landolphia*, a vine or creeper. Other sorts are obtained from trees and shrubs, the latter including a plant whose roots, growing to considerable distances underground, yield a rubber of fair value. Other portions of the world produce rubber also, but Africa and South America are the principal sources. At the present time vigorous efforts are being made to cultivate rubber trees in Ceylon, India, Straits Settlements, Mexico, etc., and with great success.

The *latex* as it issues from the tree resembles cream. The natives coagulate the rubber by different methods, the best known being the smoking process. The semi-liquid rubber is collected in a pan, and a broad stick thrust into it. A coating of the thick liquid covers this "paddle," which is then withdrawn and revolved over a smoky open fire until evaporation of the water contents of the latex takes place. As soon as one film is dry the process is repeated until the rubber forms a solid ball of considerable size. The best method, however, is that in use on cultivated plantations of rubber trees, and consists of washing the rubber, after it has coagulated, pressing into sheets, and drying thoroughly before sending it away.

It is necessary to understand the history of the rubber industry in order to appreciate the difficulties and peculiarities of the trade. The first indication in literature of rubber occurs in a Spanish history of the Indies, published in 1536, in which a game of ball is mentioned, the ball being made of a different substance than "that used by Christians." A Jesuit priest later describes this ball as of solid matter, but extremely porous and light, and notes its properties of rebounding from the ground to a much greater height than the ball in use in Europe. About 1600 another Spanish author comments on this ball as being made from a "gum," the product of a tree which, when the bark is cut, yields a milk. In 1615 still another Spanish author mentions the use of these balls, and calls the tree that furnishes the gum "the tree of Ule." He states also that the conquering Spaniards coated their hempen cloaks with this "milk"; but while the cloaks were thus rendered waterproof, light and heat soon destroyed the coating. A little before this a few samples of this elastic gum were received in Europe, but so rare were these that they sold at a guinea an ounce. Nothing more is recorded for over a century. In 1730 the exact form of the earth was one of the interesting topics of the day, and the Paris Academy sent out two expeditions, one of which was under the direction of an eminent naturalist named Lacondamine. In 1736 this scientist sent to the Paris Academy a resinous mass, of a blackish colour, which he calls by the native name of "cahuchu," afterwards spelled "caoutchouc."[1]

The attention of other botanists and explorers was attracted to this peculiar product, and search for it was made in other parts of the world, with the result that "gums" or "resins" with similar properties were found in Guiana, Prince of Wales Island, Assam, and Madagascar.

So much for the discovery of the crude material. Meantime various scientists were experimenting in order to discover some method of employing it in the manufacture of articles for which its properties were obviously suitable. In 1768 it was known that pure ether, spirits of turpentine, and a substance known as "Dippel's animal oil" would soften and dissolve, to a greater or less extent, this elastic gum. Ether was, of course, too expensive for commercial purposes, and the commercial spirits of turpentine varied very greatly at this time and for long afterwards. Dippel's animal oil was a thick, viscid, brown oil with an unpleasant smell, prepared by the destructive distillation of bones. By using one or the other of these solvents, however, small tubes and suchlike were made in an experimental manner. Priestly, the well known English chemist, in 1770, was the first to call the attention of the world to at least one of the properties of caoutchouc, namely, its power of effacing pencil marks, and it was this use that gave caoutchouc its popular and now general name of indiarubber, *i.e.* a substance from India used as a rubber. By 1775 the use of rubber for this purpose was well established, and small squares of it could be obtained at most stationers' shops. Although many other chemists, both in this country and in France, were studying the subject, very little advance was made up to 1820. Indeed, all that was accomplished was the discovery of a slightly better method of making articles out of the crude rubber. The "bottles" of rubber (as they were then called, owing to their shape) were cut up into thin, narrow strips of the most convenient size. These were immersed in ether for a short time until they became soft and swollen. The strips were then wrapped around a shape or mandrel of suitable size, and a bandage twisted round so as to press the rubber together. As the ether evaporated the surfaces at the joins became amalgamated. In this way a number of articles were made which proved useful enough, but, of course, were clumsy and subject to many disadvantages. They became tacky in hot, and cracked in cold weather, and the rubber quickly deteriorated. Many attempts were also made to waterproof cloth by means of solutions of rubber; but while some of these efforts doubtless proved successful for special purposes of limited scope, none proved of commercial importance. The pioneer in rubber who advanced the industry most in England

[1] The pronunciation of "caoutchouc" has given rise to much embarrassment as well as argument. There are at least six recognised pronunciations used in the trade. Webster states that the proper pronunciation is *koo-chook*. This is probably the worst rendering. Two others only need be mentioned: *cow-chook*, and, to our mind best of all, as resembling the native name, *ca-oot-chew*.

was Thomas Hancock. In 1820 he took out his first patent in rubber, but finding that with the crude methods then in use it would be impossible ever to bring rubber into extended use, he set about investigating the subject. He discovered that if the rubber as imported was subjected to heavy pressure and friction, such as would take place by its repeated passage between rotatory cylinders, it became a homogeneous mass. The machine he invented for this purpose was first called a PICKLE, then MASTICATOR, the latter being the name now in use. Rubber, however, in its natural or cleaned condition becomes sticky in hot weather and cracks in cold. Further experiments were required in order to discover some method of freeing it from these defects. The following is a brief list of the important discoveries:

WATERPROOFING.—MACINTOSH in 1823 discovered that coal tar naphtha would dissolve rubber, and with this solution he coated fabrics. The solvent evaporating left a thin film of rubber, thus rendering it air and waterproof. This is now known as PROOFING, and the garments as mackintoshes.

VULCANISATION. CURING.—Despite the progress being made in the use of rubber it had still the grave disadvantage of being influenced by change of temperatures. The discovery of a process for rendering rubber indifferent even to extreme heat or cold was made independently by Charles Goodyear in America and Thomas Hancock in England. Vulcanisation consists of the mechanical mixture of dry rubber with sulphur, and the exposure of the compound to heat (from 120° to 136° C. for varying lengths of time, from twenty minutes to three hours). The theory of vulcanisation as to whether a chemical change takes place or whether the action is catalytic is still in dispute. The effect of vulcanisation is to change the rubber from a plastic mass, which becomes sticky on heating and brittle on exposure to low temperatures, into a substance elastic, but not plastic, unaltered by moderate temperatures and much less liable to deteriorate by age. The COLD CURE is another method of vulcanisation which is applied to thin articles, and consists of mixing chloride of sulphur in bisulphide of carbon and DIPPING the rubber in the mixture. The effect produced is similar to vulcanisation, *but only the surface of the article is changed. See* VULCANISING INGREDIENTS, FILLERS, *and* SUBSTITUTES, *below*.

EBONITE, HARD RUBBER, VULCANITE.—Nelson Goodyear discovered that if rubber was mixed with a very large percentage of sulphur and exposed to a high temperature for a considerable time, the result was a substance altogether different in properties from rubber. This ebonite is akin to whalebone in some of its properties, like ivory in others. Great modifications are possible, and depend upon the amount of sulphur and the time the substances are subjected to heat. There is, therefore, no true dividing line between a soft rubber and a hard rubber, nor is it possible to define a hard rubber. It may be made as flexible as whalebone or as stiff and unyielding as ivory, and the gradations between are endless.

MOULDING.—Hancock in 1846 put into practice the system of moulding articles in rubber, an invention of the utmost utility. This method of manufacture consists in filling a mould or shape with the sulphur and rubber mixture, applying pressure to the parts of the mould and vulcanising. The resulting product reproduces in permanent form the most delicate chasings and decorations both in soft rubber and in ebonite, a good example of the latter being the fountain pens so common to-day.

THE MANUFACTURE OF RUBBER ARTICLES.—A brief outline of the methods used in manufacture will give the reader a better knowledge of the subject than further details. The crude rubber is first put through the WASHING MILL. This consists of two heavy fluted rollers revolving at different speeds. The rubber is formed into a thin corrugated sheet by its frequent passage between these rolls, and thoroughly washed by a stream of water playing upon it during the process. In this state it is taken to the DRYING ROOM, where it is allowed to remain until every trace of moisture is removed. At the present time this slow method is done away with in some factories, and the rubber is put into a hot chamber or dried *in vacuo*. The dried sheets are then put through the MASTICATOR or MILL until it becomes a softened homogeneous mass. It is then put on to the MIXING MILL, where two rolls running at different speeds very quickly force into the rubber the sulphur and such other ingredients as may be thought best to add to the mixture. *See* FILLERS, *below*. The mixed rubber is then put into moulds and vulcanised, or put through the CALENDER, which is simply another form of mixing mill, and is used to form the mixed rubber into sheets of the most convenient size and thickness for subsequent use. The calender is also employed when the mixed rubber is to be used with a fabric. Both the fabric and rubber are passed through the rolls, and by means of great pressure the rubber is forced into the interstices of the fabric. Some calenders have smooth rolls, others have decorative lines engraved upon them, etc.

After the rubber is got into the desired form it is vulcanised, that is, subjected to heat. The simplest form of vulcaniser is that used in the manufacture of rubber stamps; this is simply a letter copying press, the bottom plate of which is heated by a gas jet.

HOLLOW WORK.—This merits special reference because of the almost universal use of articles manufactured by this method, *i.e.* bulbs, balls, dolls, etc. From the sheeted mixture of rubber and sulphur segments are stamped out of suitable size. These segments are fitted together in a mould, and a little carbonate of ammonia placed inside. The mould is then closed and put in the vulcaniser. As soon as the heat reaches the carbonate of ammonia it volatilises into a gas, which forces the rubber against the sides of the mould into every crevice, and retains it there until it assumes a permanent form.

CUT SHEET WORK.—Many articles of rubber are produced in a simple manner from sheets. Before vulcanisation the freshly cut edges of rubber have the property of great adhesiveness. In the formation of articles from sheet, therefore, as soon as the sheet is cut into convenient size, the edges are put together and lightly pressed or tapped, when they adhere, or a little solution is applied with the same result.

VULCANISING INGREDIENTS, FILLERS, AND SUBSTITUTES.—While sulphur is the principal substance used to bring about the change in rubber known as vulcanisation, there are other substances containing sulphur which bring about the same result. The two most used are golden sulphuret of antimony and sulphide of zinc.

FILLERS is the name applied to a great number of substances mixed with rubber for various purposes, and as this portion of the subject is little understood, the following notes may show that mere adulteration is not the principal object aimed at.

The ELASTICITY of soft rubber goods is often increased by the addition of vermilion and slaked lime, or by admixture with asphaltum or colophony. The RESISTANCE TO PRESSURE is increased to a more or less degree by the addition to the mixing of zinc oxide, calcined magnesia, asphaltum, or chalk. The MECHANICAL STRENGTH of soft rubber is improved by the addition of such mineral substances as magnesia, litharge, chalk, lime, zinc oxide, and in some cases by asphaltum, and, it is said, glycerine. The INSULATING PROPERTIES of pure rubber are not so great as a mixture of rubber and paraffin wax, and the addition to rubber of zinc oxide, lime, magnesia, and white and brown substitutes in comparatively small quantities also improves its dielectric properties. The RESISTANCE TO ACIDS is increased more or less by the addition of organic compounds. The ACTION OF OILS upon rubber is lessened by the addition of litharge and zinc oxide to the mixing. Rubber by itself is not necessarily the best material for a particular purpose; in many cases it is the worst, or at least one of the worst. The use of rubber is only the means to an end, and the whole art of manufacture is to arrive at the best means at the smallest expense. To illustrate the point take the case of rubber belting. Apart altogether from the expense of using pure rubber, it would be inadvisable to do so, since the elasticity of pure rubber subjected to the constant strain of the pulleys would result in the separation of the rubber from the fabric. In consequence the elasticity has to be reduced and the mechanical strength increased. Now all inorganic (mineral) substances in a mixing reduce the elasticity of rubber, and, referring to the above, it will be seen that the addition of such mineral substances as zinc oxide, litharge, magnesia, etc., improves the mechanical strength of rubber. It is obvious, therefore, that in a belting the use of pure rubber would not only be more expensive, but would be vastly less efficient than a mixing containing rubber plus something else.

SUBSTITUTES for rubber are very numerous, but few have been successful. The latter are, as a rule, made from oxidised oils or from oils that have been treated with sulphur or chlorine. These are useful for certain purposes when mixed with rubber, because they lessen the cost while not interfering with the efficiency of the article.

RECLAIMED RUBBER.—This is now used in great quantities, and affords a perfectly safe method for the production of rubber goods at a moderate cost. Old rubber goods are collected and treated by one of several secret processes, which remove not only the dirt and fabric, but also a portion of the sulphur used for its original vulcanisation. The rubber is ground into a fine powder, then sheeted, and sold in various grades, according to the class of material from which it was made.

RUBBER AS APPLIED TO INSULATION.—In the electrical industry rubber is widely applied as an insulating material. It is used either in the form of a thin plastic mass, which surrounds the wire, and is then vulcanised, or in the form of tape, either for direct insulation or for making joints. In the form of Vulcanite or Ebonite it is of even greater service in the shape of plates, tubes, rods, handles for switches, etc. In submarine cable work vulcanised rubber has been used with success, though for some reason its use in this direction has never become very great. In 1904 a discovery was made by which rubber could be so altered in character as to present and actually have most of the characteristics of gutta-percha. This invention consisted in the intimate mixture of rubber with a wax whose melting point had been artificially heightened. Reports upon this invention show that so far as it has been applied it fulfils its claims in a satisfactory manner.

Rubbers, Condenser (*Textile Manufac.*) The pairs of rubbers which have a transverse as well as a rotary motion, so that they both rub and carry the sliver of fibres from the stripping roller to the condenser, causing the flat sliver to have the form of a soft, unspun thread.

Rubbing Board (*Foundry*). A small board used for smoothing flat faces of sand in large moulds.

Rubblework (*Build.*) Masonry built of irregular-sized or broken stone.

Rubellite (*Min.*) A red or pink variety of TOURMALINE (*q.v.*), used as a gem. *See also* PRECIOUS STONES. This variety comes chiefly from Siberia, Ceylon, and Ava.

Rubens' Brown (*Paint.*) An ochreous brown, somewhat lighter than Vandyke brown. It is now obsolete in this country.

Rubens' Madder (*Paint.*) One of the madder lakes, rich in hue. Now obsolete under this name. *See* LAKES.

Ruberythric Acid (*Chem.*) $C_{14}H_6O_2(OH).O.C_{12}H_{14}O_8(OH)_7$. The glucoside of alizarin (*q.v.*) Yellow needles, soluble in hot water; slightly soluble in alcohol; soluble in alkalis with red colour. Hydrolysed by dilute sulphuric acid to alizarin and glucose. It is obtained from madder root by boiling with absolute alcohol.

Rubicelle (*Min.*) An orange red variety of SPINEL (*q.v.*), used as a gem.

Rubidium (*Chem.*) Rb. Atomic weight, 85. A silvery white metal; melts at 38°; decomposes water like potassium, which it closely resembles. It may be obtained by heating the hydroxide with magnesium. It occurs widely distributed, but in small quantity; it is found in lepidolites, in carnallite, in many mineral springs, in argol, tobacco ash, in beetroot. Its salts are quite similar to those of potassium, but the platinum double chloride is much less soluble in water than that of potassium, and this fact enables them to be separated. Rubidium gives a characteristic flame spectrum, two lines in the violet and two in the red being very characteristic. Rubidium bromide is occasionally used in medicine.

Rubric. (1) A mediæval manuscript or early printed book in which the initial letters were written or printed in red, or in which some portion of the text was written or printed in red to distinguish it. (2) The title of a statute, which was formerly written in red ink. (3) In prayer books, the directions for conducting the service, often printed in red; hence (4) An ecclesiastical injunction or rule.

Rubricated Letters (*Typog.*) Initial or capital letters printed in red ink.

Rubus (*Botany*). An important genus of the order *Rosaceæ*, including the Raspberry (*R. idæus*), Cloudberry (*R. chamæmorus*), Blackberry (*R. fruticosus*), Dewberry (*R. cæsius*).

Ruby (*Typog.*) *See* TYPE.

——, **Almandine** (*Min.*) A violet variety of SPINEL (*q.v.*), used as a gem.

——, **Balas** (*Min.*) A rose red variety of SPINEL (*q.v.*), used largely as a gem under the name RUBY.

Ruby, Oriental (*Min.*) This is the true RUBY; it is a variety of CORUNDUM (*q.v.*) of a characteristic red colour, known as "pigeon's blood." The chief localities for the true Ruby are Burmah, Ceylon, and China. *See also* PRECIOUS STONES.

Ruby Pin *or* **Roller Pin** (*Watches*). The impulse and unlocking pin of a lever escapement, acted upon by the fork of the lever, and fixed in the roller on the balance staff. *See* LEVER ESCAPEMENT.

Ruby Silver (*Min.*) *See* PYRARGYRITE *and* PROUSTITE.

Rudented (*Architect.*) *See* CABLED COLUMN.

Ruhig (*Music*). The German equivalent to Calmato. Quiet, calm.

Ruhmkorff's Coil (*Elect.*) An INDUCTION COIL (*q.v.*)

Rule (*Eng., Carp., etc.*) The measuring instrument used in a great variety of trades. It is usually made of boxwood or of steel, and divided into inches and fractions of an inch. *See* WEIGHTS AND MEASURES.

—— (*Typog.*) Strips or lengths of metal or wood of the same height as type and of different widths. The face or printing surface may be plain or ornamental. Brass rule ranges from 12 to pica up to pica in thickness; zinc or wood rule usually from nonpareil upwards.

Rule Border (*Typog.*) Metal or other border lines to form a frame or line round a page.

Rule Cutter (*Typog.*) A small machine for cutting brass or other rule in required lengths.

Ruling Gradient (*Civil Eng.*) *See* GRADIENT.

Rum. A spirit obtained by distillation from the fermented skimmings of sugar boilers or the drainings of sugar barrels. When first distilled it is colourless, but is afterwards coloured with burnt sugar. The amount of alcohol present is from 50 to 60 per cent.

Rumble (*Eng.*) A revolving cylinder, inside which small castings are sometimes placed, in order that the sand, etc., from the mould may be removed by their rubbing together

Rumford's Photometer (*Light*). *See* PHOTOMETERS.

Run (*Build., etc.*) A term applied to Lineal measurements, which are said to be made by the "foot run," etc.

—— (*Eng., Carp., etc.*) The deviation of a tool, *e.g.* a saw or drill, from its proper direction while in action.

—— (*Mining*). (1) The direction of a vein. (2) The falling in of parts of a working.

—— (*Printing*). The number of impressions taken from a forme.

—— (*Textile Manufac.*) An American counts base for yarns, being a length of 1,600 yards. A 1-run yarn equals 1,600 yards to 1 lb. *See* COUNTS.

Runner (*Foundry*). The channel by which fluid metal runs into a mould. *Cf.* GATE.

Runner Head (*Moulding*). The mass of solidified metal filling the top of a runner (*q.v.*) These pieces of metal are usually broken off while still hot.

Runner Pin *or* **Stick** (*Foundry*). A rod used for forming a runner (*q.v.*) in a mould; it serves as a pattern for the channel, and is withdrawn in the usual way after the sand has been rammed round it.

Runners (*Typog.*) Figures placed down the side of a page to indicate the position and number of a particular line.

Running (*Music*). A defect in an organ which allows a pipe or pipes to speak when only one or two soft stops are drawn out. It is caused either by the upper board (*see* ORGAN, p. 439) not being screwed down tight, or by the wind getting from one channel to another.

Running Centre Chuck (*Eng.*) A DRIVING CHUCK (*q.v.*)

Running Down (*Met., etc.*) Melting a quantity of metal.

Running Gate (*Foundry.*) A RUNNER (*q.v.*), as opposed to a RISER (*q.v.*)

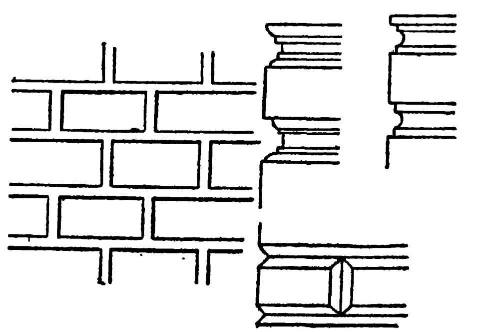
Run On (*Typog.*) *See under* PROOF CORRECTIONS.

Rupert's Drop (*Glass Manufac.*) A small portion of molten glass, in the shape of a tear, which has been dropped into boiling water, thereby becoming case hardened. Should the end of the tear be broken or the surface cut, the entire mass will break up into small fragments. This shows the necessity for annealing glass.

Russia Leather. Originally a speciality of Russia, where it was made from the skins of young cattle, but now made in many other countries besides and from various skins, *e.g.* sheep and goat skins. After being tanned like other light leathers (*see* LEATHER MANUFACTURE), it is treated on the flesh side with an oil distilled from birch bark and buds, which gives it the characteristic smell. Genuine Russia leather is very durable and is extensively used in the more expensive styles of bookbinding.

Rust (*Chem.*) A name given to the product formed by the oxidation of iron under various conditions. If iron is strongly heated in air it forms a mixture of oxides varying in composition between Fe_3O_4 and Fe_2O_3, the latter being the richer in oxygen. When iron is exposed to air at the ordinary temperature it slowly rusts; this also is a process of oxidation, leading ultimately to ferric hydroxide, $Fe(OH)_3$; iron does not rust in quite dry air, but ordinary air contains water vapour and carbonic acid, and these cause iron to rust in air. The action is facilitated by presence of acids and retarded by alkalis. To prevent iron rusting it is galvanised—that is, coated with zinc; or it is treated by Barff's process (*q.v.*)

Rustication (*Architect.*) Any method of emphasising the joints in masonry. This can be done either



RUSTICATION.

by rebating, chamfering, or moulding the stones at the joints, or by several methods of working the face of the stones, such as vermiculating and hammer dressing.

Rusting. The surface of iron is sometimes coated with rust intentionally, *e.g.* iron patterns are rusted and then varnished with shellac.

Rust Joint (*Eng.*) A joint in iron piping made by filling up the gap with a mixture of iron turnings and sal ammoniac (ammonium chloride); this rusts into a hard, watertight mass.

Rustre (*Her.*) A pierced lozenge. The piercing is round and must not be confused with the Mascle, which is a lozenge voided. *See under* HERALDRY.

Ruthenium (*Chem.*) Ru. Atomic weight, 102. A rare metal occurring in small quantity along with platinum. It is white, very difficultly fusible, insoluble in acids, oxidised on heating in air. It forms chlorides, $RuCl_2$ and $RuCl_3$, and oxides, RuO, Ru_2O_3, RuO_2, and RuO_4. RuO_4 is volatile. It also forms ruthenates (red coloured) and perruthenates (green coloured), which resemble the manganates and permanganates in their behaviour.

Rutherford's Maximum and Minimum Thermometer (*Heat*). *See* MAXIMUM AND MINIMUM THERMOMETERS.

Rutile (*Min.*) Oxide of Titanium, TiO_2. Titanium = 61, oxygen = 39 per cent. Tetragonal, often in acicular aggregates, sometimes radiating through Quartz crystals. Colour brown to black. Sometimes in geniculate twins. Some localities are Glen Finnart, Crianlarich, and Killin, in Scotland; Co. Donegal; Limoges; Castile; St. Gothard; Brazil; Brevig, in Norway; Massachusetts, etc.

Rybat (*Build.*) A Scotch term for the stones (inband and outband) that form the reveal, recess, and jamb of an opening.

Rye. *Secale cereale* (order, *Gramineæ*). In composition rye closely resembles wheat, its proteids forming, with the addition of water, a kind of glutin. Rye bread in nutritive value falls little short of wheat, but it is somewhat heavy, very acid, indigestible, and apt to cause diarrhœa.

Rymer (*Eng.*) A REAMER (*q.v.*)

S (*Chem.*) The symbol for SULPHUR (*q.v.*)

Sable (*Her.*) Black. This tincture is represented by vertical and horizontal lines crossing. *See* HERALDRY.

Saccharic Acid (*Chem.*) $COOH(CHOH)_4COOH$. A white deliquescent solid; soluble in water and in alcohol; decomposes at 100°; its solution is dextrorotatory, and the rotation increases on standing. It readily forms a lactone—

$$\underbrace{COOH.CHOH.CH.(CHOH)_2CO}_{O\text{———————}}$$

which crystallises in leaves. The acid does not reduce Fehling's solution, but reduces warm ammoniacal silver nitrate. Hydrochloric acid reduces it in part to adipic acid, $COOH(CH_2)_4COOH$; concentrated nitric acid oxidises it to oxalic and tartaric acids. Its ammonium salt yields pyrrole (*q.v.*) on dry distillation. Saccharic acid is prepared by oxidising glucose or starch with nitric acid of specific gravity 1·15. The acid is isolated by making the acid potassium salt, which is sparingly soluble in water, decomposing this with silver nitrate, and treating the latter with hydrochloric acid.

Saccharimeter. An apparatus for measuring the amount of rotation of the plane of polarisation produced by a solution of sugar or other optically active substance. *See* POLARISATION.

Saccharimetry. The measurement of the amount of sugar in a given volume of solution by means of a SACCHARIMETER. *See* POLARISATION.

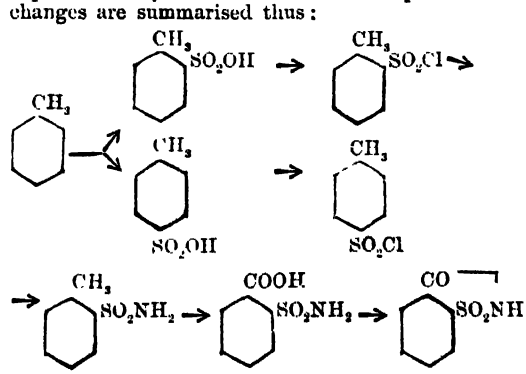
Saccharin (*Chem.*) This name has been given to two totally different compounds: (1) The LACTONE OF SACCHARINIC ACID—

$$\begin{array}{c} \qquad\qquad\qquad\qquad\quad CH_3 \\ CH_2OH.CH.CHOH.\overset{|}{C}.OH. \\ \qquad\quad |\qquad\qquad\qquad | \\ \qquad\quad O\text{————————}CO \end{array}$$

It is a solid which crystallises in shining prisms showing double refraction. It is obtained by adding fresh slaked lime to a boiling dilute solution of dextrose or lævulose. The calcium is removed from the cooled and filtered solution by carbon dioxide and oxalic acid. On concentrating the filtrate from the calcium carbonate and oxalate, saccharin crystallises out after some time. (2) The ANHYDRIDE OF ORTHOSULPHAMIDOBENZOIC ACID—

$$C_6H_4\left\langle\begin{array}{c}CO\\SO_2\end{array}\right\rangle NH$$

It is known by many names, *e.g.* sulphobenzoimide, benzoylsulphonamide, etc. It is usually met with in the form of a white powder, which really consists of very small crystals; melts at 220°; sparingly soluble in cold water, much more soluble in hot water and in alcohol; soluble in acetone, from which it crystallises well. Saccharin has an intensely sweet taste; estimates of its sweetness vary from 240 to 550 times that of cane sugar (according to the purity of the product and delicacy of the sense of taste in the observer); hence it is now much used as a sweetening agent, but, unlike sugar, it is not a food. Like other imides, it behaves as an acid, forming salts with alkalis which are very soluble in water and still retain the sweetness of saccharin itself; also it forms an ethyl derivative with ethyl iodide, which is tasteless, and an acetyl derivative with acetyl chloride. Saccharin is prepared from toluene by acting upon it with concentrated sulphuric acid at a temperature not exceeding 100°. The mixture of ortho- and paratoluene sulphonic acids is made into the sodium salts, and these are acted on by phosphorus trichloride in a stream of chlorine. The phosphorus oxychloride produced is distilled off, and on strongly cooling the remaining liquid much of the paratoluene sulphonic chloride crystallises out. The still liquid portion is treated with dry ammonium carbonate when the amide is formed. The amide is oxidised by potassium permanganate solution, the liquid being always kept neutral by addition of alkali as required. The changes are summarised thus:



Prepared in this way the product is contaminated

with 30 to 40 per cent. of parasulphamidobenzoic acid. To free it from this, advantage is taken of the fact that the para-acid is almost insoluble in hot xylene, while saccharin is easily soluble (patented process). Saccharin is also made by other processes, all protected. Owing to its extensive use as a sweetening agent in place of sugar, there is a heavy duty (twenty shillings per pound) on saccharin.

Saccharose (*Chem.*) A name for CANE SUGAR (*q.v.*)

Sackbut (*Music*). A musical instrument. (1) That mentioned in the Bible was a species of harp. (2) The old English bass trumpet, having a slide like a trombone.

Sacring Bell, Sancte Bell, Sanctus Bell. In the Roman Catholic Church the small bell that is rung at the singing of the *Sanctus* and the Elevation of the Host.

Sacristy (*Architect.*) A room either in or adjacent to a church. It contains the vessels used in various ceremonies, and is used as a robing room by the priest. It is more generally known as the VESTRY.

Saddle (*Eng.*) (1) The support or bed on which a boiler rests. (2) The baseplate of various parts of machines, especially the baseplate of a Slide Rest (*q.v.*)

—— (*Plumb.*) The piece of lead over the rolls (*q.v.*) on a flat.

Saddle Backed (*Build.*) A form of coping stone weathered (sloping) on the top towards both sides of a wall.

Saddle Boiler (*Build.*) A form of boiler used for heating water in a house. The boiler is arched at the base, the arch serving as a conduit for the products of combustion between the grate and the chimney.

Saddle Cramp (*Carp. and Join.*) A wooden cramp for wedging-up stairs.

Saddle Flange (*Eng.*) A support curved so as to fit a cylindrical object which rests upon it, *e.g.* a large pipe.

Saddle Key (*Eng.*) A KEY (*q.v.*) whose lower surface is curved so as to rest on a shaft, instead of being let into a recess or key way or lying on a flat filed on the shaft.

Saddle Tank (*Eng.*) A water tank fitting over the boiler of a locomotive, like a pack saddle.

Safe (*Plumb.*) A lead tray laid under baths, closets, etc., to catch water that splashes over.

Safe Edge (*Eng.*) An edge of a file which is left unprovided with teeth; it can be used in an angle or corner in order to act on one surface only.

Safe Load (*Eng., etc.*) The amount of load or force to which a structure or member of a structure can be subjected without risk. It should be so chosen that the strains produced always lie well within the ELASTIC LIMIT (*q.v.*) of the material.

Safety, Factor of (*Eng., etc.*) *See* FACTOR OF SAFETY.

Safety Fuse, Cut Out, etc. (*Elect. Eng.*) A device by which a circuit is broken when the current in it rises above a certain value. A FUSE is the simplest form; it consists of a short wire or strip of tin or some fusible alloy, which melts if the current rises to a certain value.

Safety Ladle (*Met., Foundry, etc.*) A large foundry ladle, provided with gearing by which it can be tilted gradually without the risk of overurning.

Safety Lamp (*Mining*). A lamp designed to give light in gaseous workings without the danger of igniting inflammable mixtures of firedamp and air. The construction of the ordinary safety lamp is based upon the principle that although air can enter through the meshes of a wire gauze surrounding the flame, no flame can pass from the inside to the outside of the gauze, because the metallic wires conduct away the heat so quickly that the temperature of the gases outside cannot rise to the point of ignition. There are many types of safety lamps, but although they differ from each other in such details of construction as size, shape of glass and gauze, method of lighting and locking, arrangements for testing for gas, the wire gauze is retained in every type, no better means of preventing the communication of flame from the inside to the outside of the lamp having been discovered. A few electric lamps are in use, but these are unsuitable for fiery mines, as it is necessary for a lamp not only to be safe in inflammable mixtures, but to give *immediate indication* of the presence of gas in the workings. *See* METHANE.

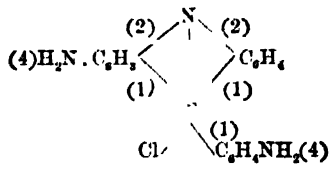
Safety Lift (*Eng., etc.*) A lift or hoist provided with some means of preventing a sudden descent.

Safety Plug (*Eng.*) A plug of fusible metal used in boilers, etc. It melts and allows the escape of steam if the temperature (and therefore the pressure) rise above a certain point.

Safety Valve (*Eng.*) A valve in a boiler which opens and allows the escape of steam when the pressure exceeds a certain value. The valve is kept closed either by springs or by properly adjusted weights. The weights may act directly (as in the Cowburn valve) or may be attached to a lever, in which case the force exerted on the valve is adjustable within certain limits. *See* STEAM ENGINE.

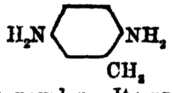
Safflower (*Botany*). The compressed flowers of *Carthamus tinctorius* (order, *Compositæ*)—a plant cultivated in the south of Europe, Egypt, etc—are used as a yellow and red dye for silk. When powdered they are the source of one kind of rouge (*q.v.*)

Saffranines (*Chem.*) A class of dyes the simplest member of which is *Phenosaffranine* (diamidophenylphenazonium chloride)—



which forms green leaflets or steel blue needles, according as it is crystallised from dilute hydrochloric acid or water. Its solution is red, and the alcoholic solution shows yellow-red fluorescence; with a large excess of hydrochloric acid it is blue (diacid salt); with concentrated sulphuric acid the solution is green (triacid salt). It dyes cotton, mordanted with tannin and tartar emetic, red; on silk it gives a rose colour. On reduction with stannous chloride it yields the leuco-compound; on exactly precipitating the sulphate with baryta water it yields the colour base which has the same colour as its monacid salts (red). Phenosaffranine is obtained by oxidation in neutral solution with potassium dichromate, of (1) a mixture of paraphenylenediamine and aniline in the proportion of

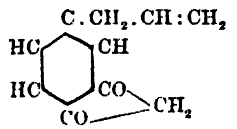
one molecule of the former to two of the latter; (2) a mixture of dipara-amidodiphenylamine and aniline in molecular proportions. An indamine (*q.v.*) is an intermediate product. Ordinary saffranine is a mixture of phenotolusaffranine and tolusaffranine, and is obtained by oxidation of a mixture of aniline, orthotoluidine, and paratoluylenediamine—



It is a red-brown powder. Its properties are very similar to those of phenosaffranine. A 0·1 per cent. solution in presence of caustic potash forms a delicate and reliable test for sugar (dextrose) in urine; the dextrose turns it yellow on warming.

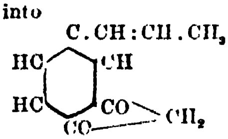
Saffron (*Botany*). The dried stigmas of the flowers of *Crocus sativus* (order, *Iridaceæ*) yield the SAFFRON of commerce. It was once used as an orange dye, but is now chiefly employed as a flavouring agent.

Safrols. (1) SAFROL,



(Allylpyrocatechol methylene ether). A colourless liquid; melts at 8°; boils at 232°; the smell of essential oil of sassafras is due to safrol, which forms about 90 per cent. of this oil. It is largely used in perfuming cheap soaps. It occurs in oil of sassafras, oil of camphor, and in the oil from *Ilicium religiosum*. From the first of these oils it is easily obtained by fractional distillation and freezing of the fractions; oil of camphor also furnishes large amounts of safrol. When heated with alcoholic potash it is converted into

(2) ISOSAFROL,



(Propenylpyrocatecholmethylene ether). A colourless liquid; boils at 249°; smells like safrol, but weaker. It is made from safrol, as mentioned above. On oxidation with potassium dichromate and sulphuric acid, it gives piperonal and acetaldehyde. *See* PIPERONAL.

Sag (*Eng., etc.*) A bending downward, produced in a member of a structure either by its own weight or by the load which it carries. *See* DEFLECTION.

Sagger (*Met.*) A cast iron box or crucible in which castings are packed for annealing in the preparation of malleable castings.

—— (*Pot.*) *See* SEGGAR.

Sago (*Botany*). The starchy matter obtained from the pith of the SAGO PALM (*Metroxylon sagu*; order, *Palmæ*), a native of the East Indies. It is prepared by crushing and repeated washings.

Sagum (*Archæol.*) The cloak of the Roman soldier, consisting of an oblong piece of coarse cloth fastened on the left shoulder. *Cf.* CHLAMYS *and* TOGA.

Saint Bees' Sandstones. *See* BUILDING STONES.

Saint Elmo's Fire (*Meteorol.*) An electrical discharge resembling the brush discharge of electrical machines, seen at the tops of trees, spires, masts, and other pointed objects during thunderstorms.

Salade (*Arm.*) An open form of helmet or headpiece, sometimes provided with a movable visor; worn in the fifteenth century and after. It succeeded the bascinet (*q.v.*) *See also* ARMOUR *and* MORION.

Sal Alembroth (*Chem.*) *See* MERCURY COMPOUNDS.

Salamander (*Met.*) The mass of hard slag which remains on the hearth of a furnace when the fires are drawn.

Sal Ammoniac (*Chem.*) Ammonium chloride. *See* AMMONIUM COMPOUNDS.

—— (*Min.*) Ammonium chloride, NH_4Cl; cubic; occurring in minute octahedrons or as an efflorescence. White or yellowish. Very soluble in water. It is found rarely in relation to some coal and shale beds, as at Hurlet, near Paisley; more often in volcanic regions, as at Vesuvius, Etna, and Stromboli.

Salcional, Salicet, *or* **Salicional** (*Music*). An organ stop of soft tone and reedy quality, and having a very small scale. It is very similar to the dulciana.

Salicaceæ (*Botany*). A dicotyledon order, including the Willows and Poplars.

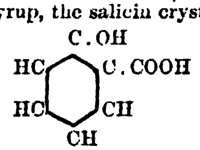
Salicin (*Chem.*) $C_6H_4\begin{cases} OC_6H_{11}O_5 \\ CH_2OH \end{cases}$

A glucoside. It forms small shining trimetric crystals; melts at 188°; soluble in water (1 in 23) and in alcohol; bitter taste; lævorotatory. Used in medicine as a stomachic and in rheumatism. On gentle oxidation by nitric acid it yields the aldehyde helicin—

$$C_6H_4\begin{cases} OC_6H_{11}O_5 \\ CHO \end{cases}$$

Hydrolysed by ptyalin, emulsin, and dilute acids to glucose and saligenin, the latter resinising when acids are used. It occurs in the bark of many varieties of willow and poplar. It is obtained from willow bark by boiling with water, filtering, and concentrating the filtrate, which is then digested for twenty-four hours with oxide of lead; on filtering and evaporating to a syrup, the salicin crystallises out.

Salicylic Acid,



(Orthohydroxybenzoic acid). White small needles usually, or long needles or prisms; melts at 156°; slightly soluble in water (1 part in 444 at 15°); much more soluble in hot water; soluble in alcohol, ether, and chloroform; taste sweet first, acid to burning afterwards. Powerful antiseptic, and therefore largely used as a food preservative, especially in jams, which practically always contain it (1 in 3,500 and more); also used in medicine, both as an ointment and as a specific in rheumatic fever. (The sodium salt, which is much more soluble in water than the acid, is much used.) The artificial acid is liable to contain parahydroxybenzoic acid and the methyl homologues of salicylic acid, of which orthocresotic acid, $C_6H_3.CH_3.OH.COOH.(1:2:3)$, is certainly poisonous; but by using pure phenol and properly regulating the temperature the artificial acid can be obtained pure. Salicylic acid distils in steam; ferric chloride gives a violet colour to its solution. When heated alone it gives some salol (*q.v.*) and xanthone (*q.v.*); heated with soda lime, it gives phenol. On reduction with sodium

and amyl alcohol it gives normal pimelic acid, $COOH.(CH_2)_5COOH$. With caustic potash or soda it forms two series of salts, *e.g.*

$$C_6H_4\begin{cases}OH\\COOK\end{cases} \text{ and } C_6H_4\begin{cases}OK\\COOK\end{cases}$$

the latter, formed by using excess of the alkali, being decomposed by carbonic acid into the former. Salicylic acid occurs in the form of its methyl ester in oil of wintergreen and oil of sweet birch (*Betula lenta*); both oils contain about 99 per cent. of the ester. It is prepared from these by hydrolysis with caustic soda—

$$C_6H_4\begin{cases}OH\\COOCH_3\end{cases} + NaOH = C_6H_4\begin{cases}OH\\COONa\end{cases} + CH_3OH.$$

The methyl alcohol is distilled over; the residual liquid is diluted, filtered, and acidified with hydrochloric acid, when the salicylic acid crystallises out. It is purified by recrystallisation. The artificial acid is prepared from sodium phenate; phenol is dissolved in caustic soda, and the solution evaporated to dryness with constant stirring:

$$C_6H_5OH + NaOH = \underset{\text{Sodium Phenate.}}{C_6H_5ONa} + H_2O.$$

The dry sodium phenate is heated in a stream of carbon dioxide at 180 to 200°, when phenol sublimes and disodium salicylate remains:

$$2C_6H_5ONa + CO_2 = C_6H_4\begin{cases}ONa\\COONa\end{cases} + C_6H_5OH.$$

The acid is liberated from its disodium salt by hydrochloric acid. If potassium phenate is used instead of sodium phenate, a mixture of the dipotassium salts of orthohydroxy- and parahydroxybenzoic acids is obtained at 150°; at 220° only dipotassium parahydroxybenzoate is formed. Another method is to heat the sodium phenate at 120° to 130° with carbon dioxide under pressure, when the sodium phenyl carbonate first formed is converted by a molecular rearrangement into sodium salicylate:

$$C_6H_5ONa + CO_2 = CO\begin{cases}ONa\\OC_6H_5\end{cases}$$

$$CO\begin{cases}ONa\\OC_6H_5\end{cases} = C_6H_4\begin{cases}OH\\COONa\end{cases}$$

from which the acid is obtained as above. Salicylic acid can be obtained in many other ways, *e.g.* from anthranilic acid (*q.v.*) by the diazo-reaction (*q.v.*); by a modification of Reimer's reaction (*q.v.*)

Salicylic Acid in Foods (*Foods*). Salicylic acid is frequently added to milk and other articles of food as a preservative. According to a report of a Departmental Committee of the Local Government Board in 1901, salicylic acid should not be used in larger proportion than one grain in a pint or pound of food.

Salicylic Aldehyde (*Chem.*) $C_6H_4\begin{cases}OH\\CHO\end{cases}$ (1:2).

A pleasant smelling, colourless liquid; boils at 196°; soluble in water; ferric chloride colours its solution violet; distils in steam. It is used in perfumery, and as a flavouring agent for liqueurs. It is easily oxidised to salicylic acid, and reduced to saligenin. Does not reduce Fehling's solution. It occurs in oil of meadowsweet. Salicylic aldehyde is obtained by distilling a mixture of salicin, potassium dichromate, and very dilute sulphuric acid, and extracting the distillate with ether. It is also obtained by Reimer's reaction (*q.v.*)

Salient (*Her.*) A beast in the act of springing. *See* LION SALIENT.

Salient Angle. An external angle, one in which the apex points outward.

Salient Pole (*Elect. Eng.*) When the poles of a dynamo project inward towards the armature, from a closed ring of iron, and are each magnetised by one coil only, they are termed SALIENT POLES, as distinguished from CONSEQUENT POLES (*q.v.*) *See* DYNAMO, Fig. 1.

Saligenin (*Chem.*) $C_6H_4\begin{cases}OH\\CH_2OH\end{cases}$ (1:2).

The alcohol corresponding to salicylic acid. It is a white crystalline solid; melts at 82°; soluble in water, alcohol, ether. It is formed by the hydrolysis of salicin (*q.v.*); also by condensing phenol with either methylene chloride, CH_2Cl_2, or formaldehyde with caustic soda. Ferric chloride gives a blue colour with saligenin.

Salinometer (*Eng.*) An instrument for ascertaining the amount of dissolved salt in the water used in ships' boilers, etc. The salt increases the density and raises the boiling point of the water. If either of these quantities be determined, the amount of salt can be found from tables; or the amounts corresponding to given densities or given boiling points may be marked on the instrument.

Saliva (*Zool.*) The fluid secreted by the salivary glands. It consists of water containing mucin, ptyalin (a ferment acting on starch), and small quantities of various salts. It is the first of the various fluids which act upon food in the processes of digestion.

Salle (*Paper Manufac.*) A room devoted to sorting and packing sheets of paper.

Salol (*Chem.*) $C_6H_4\begin{cases}OH\\COOC_6H_5\end{cases}$ (Phenyl salicylate).

A white crystalline solid with faint aromatic smell; melts at 43°; boils at 172° under 12 mm. pressure of mercury; insoluble in water; soluble in alcohol; very soluble in ether and chloroform. It is used in medicine as an antiseptic and in rheumatism. Prepared by heating salicylic acid alone at 220°, or by the action of phosphorus oxychloride on a mixture of salicylic acid and phenol. Heated alone, it gives xanthone. Saponified by boiling caustic soda.

Salon (*Art*). One of the two annual exhibitions of works by living artists in Paris. One is held at the Palais of the Champs Elysées, the other at the Salon of the Champs de Mars.

Salopian (*Geol.*) The middle division of the SILURIAN ROCKS. It comprises all the strata from the top of the Lower Ludlow to that of the Tarannon Shales. In the Lake District and in Southern Scotland the rocks of Salopian age attain to a thickness of many thousand feet. The rocks above the Salopians are now classed as DOWNTONIAN and the remainder of the Silurian Rocks below as VALENTIAN. This classification is based upon the evidence afforded by the included organic remains.

Sal Prunella (*Chem.*) Potassium nitrate (*see* POTASSIUM COMPOUNDS) which has been melted and cast into balls or sticks.

Salt (*Geol.*) Salt, in the form of rock salt, occurs under a considerable variety of geological conditions; but the deposits best known on account of their economic importance occur in connection with stratified rocks, which appear, in most cases, to have been formed under arid, or even desert, conditions. In some few cases deposits of rock salt may be due to (1) the desiccation of bodies of sea water which have dried up after having been cut off from the open sea; or (2) to the drying up of large shallow sheets of sea water which have evaporated under such geographical conditions as now occur in the Runn of Cutch. But the majority appear to have originated in inland lakes. The genesis of the salt in such a case as this last may be somewhat as follows: During storms large quantities of sea spray are driven far inland by the winds, and their dissolved salts are eventually left, for a time, in the atmosphere in the form of dust. Upon these solid particles condensation of some of the aqueous vapour present in the atmosphere occurs, so that the sea salt (amongst other substances) forms the nuclei of drops of rain, flakes of snow, particles of fog, etc. Descending to the Earth, this mixture of sea salts and water flows down hill and seaward, and is usually returned to the ocean, to await the commencement of another cycle of change. But in the areas of inland drainage, such as the Dead Sea, the Salt Lake, the Caspian, and the inland lakes of Central Asia, the water is dissipated by evaporation, and returns to the clouds, leaving the dissolved constituents behind. In time these may accumulate into thick beds, which may eventually be covered by desert sands, and so be preserved for a time from waste. Salt deposits found in this way (or in others) occur on various geological horizons. In Britain they are confined to the Bunter Marls, as at Middlesboro', or to the Keuper Marls, as in Cheshire, both horizons belonging to the Upper New Red or Trias. *See* SODIUM CHLORIDE *under* SODIUM COMPOUNDS.

—— (*Min.*) *See* ROCK SALT.

——, **Formation of** (*Geol.*) The primary source of rock salt may be any one of five. (1) The salt may be simply washed out of some older rocks in which it occurred, and be subsequently re-deposited. (2) It may arise through the chemical combination of chlorine, through the medium of hydrochloric acid, with other sodium compounds. (3) It may be concentrated from the efflorescences given off by many active volcanoes, which boil off the H_2O from sea water, and use up most of the residues in making eruptive rocks. (4) It may be due to the evaporation of shallow basins of sea water in areas permanently, or periodically, cut off from the open sea; or (5) it may be of cyclic origin, as follows: The aqueous vapour present in the atmosphere undergoes condensation only upon (*a*) some few vapours, (*b*) solid particles of one kind or another. Amongst those which are most potent in this connection, particles of salt rank foremost. This salt dust, which is widely present in the lower strata of the atmosphere, is due to the action of the wind upon sea water, which it lashes into spray and drives far inland. Upon these salt dust particles much of the rain and snow that reach the Earth has been condensed. Flowing downhill and seawards, the water, with its minute charge of salt, finds its way into rivers, and thence, in usual course, back to the sea, where the cycle is re-commenced. But in the case of the areas of inland drainage, which occupy some 11,486,250 square miles, or nearly one-fifth of the total surface of the land, *the water does not return to the sea*, but is dissipated by evaporation, so that, however minute the quantity of dissolved matter it contained, in time the amount begins to tell, and in course of ages thick deposits are formed. It is mainly from such deposits that our chief supplies are drawn.

Saltando (*Music*). Jumping.

Salt Cake Process. *See* ALKALI.

Salting (*Eng.*) The deposition of salt in the boilers of ships. It is not injurious so long as the amount is small.

Saltire (*Her.*) Formed by a bend and bend sinister crossing each other. St. Andrew's Cross is a saltire. *See* HERALDRY.

Salt Lakes (*Geol.*) The majority of recent salt lakes occur within areas in which the rainfall of the hydrographical basin in which they occur is exactly balanced by evaporation. The Dead Sea, the Salt Lake, and the lakes of Central Asia are cases in point. In all of these the saltness is due to the continued accumulation of saline matters, derived in the first instance from sea spray, which has been carried down in rain water, and which, instead of being returned to the sea, as is usually the case under other geographical conditions, is left behind when the water evaporates.

Salt of Sorrel (*Chem.*) Same as Salts of Lemon (*q.v.*) *See also under* OXALIC ACID.

Saltpetre (*Chem.*) A common name for potassium nitrate. *See* POTASSIUM COMPOUNDS.

—— (*Min.*) *See* NITRE.

Salts (*Chem.*) Compounds derived from acids by the replacement of the whole or a part of the acid hydrogen by metals, or by groups of elements which act as metals. Examples:

Hydrochloric acid, HCl.	Sodium chloride, $NaCl$.
	Ammonium chloride, $NH_4.Cl$.
Sulphuric acid, H_2SO_4.	Sodium Sulphate, Na_2SO_4
	Sodium hydrogen sulphate, $NaHSO_4$.
Acetic acid, CH_3COOH.	Lead acetate $(CH_3COO)_2Pb$.
	Ethyl acetate, $CH_3COOC_2H_5$.

Salts derived from hydrochloric acid and the other halogen acids are called haloid salts. *See* HALOID SALTS. Salts like ethyl acetate, derived from an organic acid and an alcohol, or from an alcohol and an inorganic acid, are called ethereal salts or esters. *See* ESTERS. When the whole of the acid hydrogen is replaced by metal, the salt is called a NORMAL SALT. When the whole of the acid hydrogen is not replaced by metal, the salt is called an ACID SALT. An acid salt may be regarded also as a compound formed by the union of a normal salt with the corresponding acid; in some cases this appears to be the only way of regarding them, *e.g.* potassium quadroxalate, $KHC_2O_4 . H_2C_2O_4 2H_2O$. Calcium acid carbonate, $CaCO_3H_2CO_3$. When an acid is added to an excess of a base there are often formed in the case of weak bases BASIC SALTS; these may be regarded as compounds of the normal salt with the basic oxide, or as compounds derived from the basic hydroxide by replacement of part of the hydroxyl hydrogen by the acid radical: *e.g.*

$$\text{Basic bismuth chloride, } Bi_4O_3Cl_6 = Bi_2O_3 . BiCl_3.$$

$$\text{Basic lead acetate, } PbO . Pb(C_2H_3O_2)_2 . H_2O,$$

may also be regarded as $Pb \begin{cases} OH \\ OOC.CH_3 \end{cases}$

Very frequently two salts combine together to form

a complex salt, which is called a DOUBLE SALT. For example, if solutions of ferrous sulphate and ammonium sulphate are mixed together in molecular proportions, the compound ferrous ammonium sulphate, $(NH_4)_2SO_4 . FeSO_4 . 6H_2O$, crystallises out on concentrating the solution. This salt shows all the reactions of an ammonium salt, a ferrous salt, and a sulphate. But there is another kind of double salt formed in a similar way which does not show all the reactions of all the metals and acid which compose it; thus when sodium chloride solution is mixed with platinic chloride solution, a double salt is formed which does not show the ordinary reactions of platinum and a chloride, and on electrolysis only the sodium travels to the kathode. Double salts of this kind are now usually regarded as derived from complex acids. The salt just mentioned is regarded as derived from chloroplatinic acid, H_2PtCl_6, by replacement of the hydrogen by sodium. The term NEUTRAL SALT was formerly much used, and is still met with sometimes, as synonymous with normal salt; but it is best not used or only used when speaking of a salt which has a neutral action towards litmus. With regard to the action of salts on litmus, it is useful to bear in mind that salts of weak bases with strong acids turn blue litmus red, *e.g.* ferric chloride, lead nitrate; salts of strong bases with weak acids turn red litmus blue, *e.g.* sodium carbonate, sodium borate; salts of strong bases and strong acids are neutral to litmus, *e.g.* sodium chloride, potassium nitrate. *See* SOLUTIONS.

Salts in Food (*Foods*). Chloride of sodium (common salt), phosphates of lime, soda, potash, and magnesium are essential for the repair and growth of the body. Lime is required for bone formation, potash for nutrition of formed tissues. Iron is necessary for the formation of the red blood corpuscles. The absence of ordinary salt from food leads to disease and sometimes death.

Salts of Lemon (*Chem.*) Potassium acid oxalate or potassium quadroxalate—

$$KHC_2O_4 \text{ or } KHC_2O_4 . H_2C_2O_4 2H_2O.$$

It is used for removing ink stains and iron stains from linen. Poisonous.

Salt Water. In engineering phraseology this usually means SEA WATER (*q.v.*)

Sal Volatile (*Chem.*) A common name for ammonium carbonate. *See* AMMONIUM COMPOUNDS.

Samara (*Botany*). A dry, usually one-seeded fruit furnished with a projecting wing. The wing may be terminal, as in the White Ash, or it may surround the fruit, as in the Birch. Also called KEY FRUIT.

Samarium (*Chem.*), Sm. Atomic weight, 149. A rare element occurring in samarskite and thorite. It is characterised by its spark spectrum and by the absorption spectra of its salt solutions. Oxide, Sm_2O_3; very faint yellow powder; chloride, $SmCl_3 6H_2O$; topaz coloured deliquescent crystals.

Samian Ware (*Pottery*). The name given to an ancient kind of pottery, either black or red in colour, highly glazed, and with ornament in relief. It has a wide distribution.

Samovar. An urn, usually of copper, used in Russia for boiling water for making tea. It is generally heated by a charcoal fire.

Sample. A small portion of material from which the quality is to be judged.

Sampling (*Assaying, Met., etc.*) The selection of a portion of ore for analysis or assaying, such that its composition accurately represents the average composition of the whole quantity under consideration.

Sancte Bell, Sanctus Bell. *See* SACRING BELL.

Sand (*Geol.*) The term sand is applied indifferently to any finely comminuted mineral matter which has been formed by natural agencies, with the exception perhaps of the dust ejected from volcanoes. Thus there is shell sand, formed of broken shells; coral sand, of broken corals; volcanic sand, arising from broken-down volcanic rocks; and so on. But sand is usually understood to mean fine grained fragmentary mineral matter chiefly composed of quartz grains. In all cases sand of this description is of terrigenous origin, *i.e.* it has been derived in the first instance from the rocks of the land. The primary source of quartz sand is either the quartz of granites or the broken-down material of vein quartz. In no case do flints constitute the parent rock of sand of any kind. Quartz is liberated from granite usually by the chemical decomposition of the rock, started in the first instance by solutions of the humus acids, which in their turn are due to the action of bacteria upon dead organic matter. Quartz so liberated becomes reduced in size by various mechanical agencies, and is sorted out either by running water or by the action of the wind, so that grains of fairly uniform size become associated together. When sand grains are undergoing reduction by the action of running water, the reduction in the size of the grains proceeds at a slower rate with the smaller grains than with the larger, while the rounding by attrition does not, in this case, go on when the sand grains have reached dimensions such that the surface tension between the grain of sand and the water in contact with it balances the gravitational force. When a grain of sand is being worn down, its surface area does not lessen as fast as its weight does, but becomes proportionally larger, so that with each halving of the diameter of, say, a sphere, the ratio of its surface area to its weight is doubled. Thus after a certain stage of reduction is past, sand grains are buoyed up by moving water, and little or no further attrition of the sand grain is possible. Hence sea sand and river sand consist of quartz grains which are either angular or subangular, and are rarely or never round, unless they have been derived from a rock which has been formed under the conditions referred to below. But a very large proportion of the sand on the face of the globe has been formed subaërially. In desert regions, where a very high diurnal range of temperature occurs in consequence of the absence of moisture in the air, such rocks as granite break up under the heavy strain occasioned by these rapid changes of temperature. The quartz, among other substances, is set free by this disintegration, becomes further reduced in size as time goes on, and then begins to undergo transport solely by the action of the wind. This agent bowls the grains of sand against each other through very long periods of time, with the result that the sand grains finally assume a spherical, or, at least, spheroidal shape. So in desert sands, recent or fossil, a large proportion of the sand grains are rounded, instead of being angular, as sand grains of the same size would be if they had been shaped by running water.

Sandal (*Cost.*) A shoe consisting generally of a sole only, attached to the foot by thongs, cords, or loops. In some cases the sandal is supplied with

a heel piece and a cap for the toes. Sandals were worn by most of the ancient nations, and are still worn by some Oriental races. Ancient Egyptian sandals were sometimes manufactured from papyrus.

Sandal Wood, Red. The reddish brown heart wood of the stem of *Pterocarpus santalinus* (order, *Leguminosæ*) is used in medicine as a colouring agent, and also as a dye.

——, True. The true sandal wood of India is the wood of *Santalum album* (order, *Santalaceæ*), a small evergreen tree growing in South India and the Indian Archipelago. It is used in perfumery and in Indian medicine.

Sandarach. A resin used in varnish making; obtained from the tree *Callitris quadrivalvis*, which is found in the north of Africa and shipped from Mogador. Another variety has in recent years been brought to England from Australasia. Sandarach is hard and brittle, and occurs in tears which are of a yellowish white colour. It is sometimes erroneously called "gum juniper."

Sand Bag (*Foundry*). A bag made of some fabric of open texture filled with sand. By shaking the bag fine sand can be dusted over any surface in a mould to form a Sand Joint (*q.v.*)

—— (*Engrav.*) A leather covered cushion filled with sand, used by engravers to fix a plate at an angle convenient for working.

Sand Bank (*Foundry*). A sloping bed of sand on which iron pipes are often cast. The sloping position of the moulds facilitates the escape of the scum

Sand Blast (*Eng., etc.*) A jet of water and steam carrying fine sharp sand in suspension; used for sharpening files, abrading or "grinding" the surface of glass, and various other purposes. *See* GLASS MANUFACTURE.

Sand Box (*Eng.*) A box fitted to a locomotive, tram-car, etc., from which sand can be dropped on the rails in front of the driving wheels, to promote adhesion when the rails are slippery.

—— (*Foundry*). A MOULDING BOX *or* FLASK (*q.v.*)

Sand Burned (*Foundry*). A casting is said to be sand burned when a layer of partly fused silica adheres to the surface, owing to the metal having been poured at too high a temperature. The use of BLACKING (*q.v.*) prevents this fault.

Sand Dunes (*Geol.*) During storms, when the wind comes landward from the sea, considerable quantities of sand are caught up in the waves which beat on the shore. When the waves are driven upon the land, the sand grains carried by them are usually left behind, while the sea water oozes back alone to the sea. Large quantities of sea sand are thus left above high water mark, and these, sorted and re-arranged by the wind, make up sand dunes.

Sanderswood. *See* DYES AND DYEING *and* WOODS.

Sand Grain. *See* ENGRAVING AND ETCHING.

Sand Joint (*Foundry*). The parting surface between the separate parts of a mould.

Sandmeyer Reaction (*Chem.*) The reaction of diazobenzene salts with cuprous salts, described under DIAZO REACTIONS (*q.v.*)

Sandpaper (*Joinery, etc.*) Tough paper covered with finely crushed abrading material. Originally fine sand was used; hence the name. Crushed glass is now employed, and the name GLASS PAPER is therefore more correct.

Sand Pump (*Civil Eng.*) A centrifugal pump by which a mixture of sand and water is raised in dredging a sandy bottom. The pump discharges into a barge in which the sand settles, and the water is allowed to flow away.

Sand Sifter (*Foundry*). A machine used for sifting sand for foundry use.

Sandstones (*Geol.*) Rocks comprised of sand grains cemented by any one or more of various materials, such as limonite, calcite, bituminous matter, and variously coloured in accordance with (1) the nature of the sand grain, (2) that of the cement, (3) the tint subsequently imparted to the rock by infiltration, weathering, etc.

Sand Trap (*Paper Manufac.*) A long narrow box fitted with partitions, used for keeping back knots and mechanical impurities in pulp.

Sand Valve (*Eng.*) A valve used for discharging sand on to the rails in front of the wheels of a locomotive. Cf. SAND BOX.

Sandvent (*Foundry*). Holes of small diameter pierced through the sand of a mould by a rod or wire, in order to allow of the escape of the gases produced when hot metal enters the mould.

Sanger Shepherd Process (*Photo.*) *See* PHOTOGRAPHY IN COLOURS.

Sanguine. Of a blood red colour. In heraldry it is synonymous with the older term MURREY.

Sanidine (*Min.*) A glassy variety of ORTHOCLASE FELSPAR (*q.v.*)

Sanitary Wallpaper (*Dec.*) A variety of paper hangings printed from engraved copper rollers in oil colours. Ordinary paper hangings are printed in distemper colours. *See* PAPER HANGINGS.

Sanitation. Sanitation may be defined as the science of sanitary conditions, and thus comes practically within the province of the sanitary engineer. It is included in the term Hygiene, which also comprehends subjects generally dealt with by the medical man and the analyst. The subjects which come under the above definition of sanitation are numerous, but they appertain chiefly to the supply of pure air and water; the means adopted for the removal and disposal of fœtid and waste products; and the purity of food supply.

AIR.—The air we breathe is a mechanical mixture, and is composed of oxygen, about 21 per cent. by volume; nitrogen, about 79 per cent.; carbonic acid, (CO_2), about ·04 per cent.; watery vapour; small traces of ammonia. Ozone—an allotropic modification of oxygen—is also present sometimes, more especially on the sea coast. As a rule the greater the quantity of ozone present the greater is the purity of the air. The amount of CO_2 present is generally taken as a gauge for the amount of impurity, as if present in quantity it is generally associated with other and more harmful impurities. The amount of CO_2 varies from ·033 in the open country to ·054 per cent in the centre of cities. In badly ventilated rooms this percentage may rise to ·1 or even ·2. Air is polluted in many ways, but chiefly by the respiration of men and animals, by combustion, by emanations from decomposing matter of all kinds, and by countless particles of dust which have a complicated composition.

Bacteria of various kinds are also present, and these are more abundant in towns than in the country, while at a distance of 120 miles from land it is said that none exist. In inhabited rooms the ordinary impurities are derived from respiration and combustion. In respiration each adult gives off about ·65 of a cubic foot of CO_2 per hour, as well as watery vapours and organic impurities. In the combustion of coal and coal gas CO_2 is given off as well as sulphuric acid, sulphide of ammonia, water, and particles of unburnt carbon. An ordinary gas burner which burns 4 cubic feet per hour uses up the oxygen in 32 cubic feet of air, and produces about 8 cubic feet of CO_2.

VENTILATION OF ROOMS.—In order to get rid of these products, which act deleteriously on human beings, ventilation is necessary. In an ordinary dwelling house there are as a rule only two means of ventilation: the fireplace and chimney, which act as an outlet, and the windows, which may act as both inlet and outlet. A chimney acts better when there is a fire in the fireplace. The window is the best ventilator if used as it ought to be, and no ventilation can compare with what is called "perflation," or ventilation by means of the wind blowing through the room. If perflation is combined with sunshine, then a room can not only be ventilated thoroughly but also purified. In large buildings other means of ventilation are necessary, and may be either natural or mechanical. The former depends on the force of the wind and the differences of temperature for its action, while in the latter some form of mechanism such as a fan is employed. In both cases inlets and outlets must be provided. The following are a few of the appliances in use for ventilating purposes: TOBIN'S TUBES are upright inlet tubes fixed inside the room and rising at least 6 ft. above floor level. They generally have valves, and are occasionally fitted with hot water coils inside to warm the air as it passes in. SHERRINGHAM'S VALVE is a small inlet ventilator, with hinged flap, balanced so that the flap falls inwards, the current of fresh air being directed upwards. MCKINNELL'S VENTILATOR is both outlet and inlet, being composed of two tubes one inside the other, the outer acting as inlet and the inner as outlet. One of the most common outlet ventilators used is Boyle's mica flap valve, placed in an opening into the chimney of the room. Ventilating cowls are frequently used on churches, etc. These are generally either Boyle's, Banner's, or Buchan's, and act as outlets. With these proper inlets must also be provided. Ventilating grates and stoves are sometimes used, the most satisfactory of these being Douglas Galton's grate. ARTIFICIAL VENTILATION by fan is now frequently employed in churches, schools, hotels, theatres, etc., and, if the currents are properly directed, is the most satisfactory for large buildings. The air can be cooled, warmed, and purified as required.

WARMING.—In England the open fire is the principal method adopted in houses, and although the most expensive, is not only a ventilator of great value, but gives an air of comfort to a room. In recent years great improvement has taken place in the construction of open firegrates, and some of them, such as Teale's slow combustion grate, are extremely satisfactory and economical. Gas fires are now in common use, but although cleanly and convenient they are not to be recommended for use in bedrooms. STOVES of various patterns are also used, but there is always a chance of the air introduced being burnt if the stove is a ventilating one, and also of the production of carbon monoxide (CO), a very poisonous gas, if the stove is constructed of cast iron. The warming of large rooms, churches, etc., is usually carried out by means of hot water or steam pipes. The system most commonly employed consists of 4-in. iron pipes connected with a boiler heated by a furnace, in which the temperature of the water rarely reaches 212° F. In high pressure systems the water is above this temperature, and the pipes are of wrought iron and of smaller diameter.

WATER AND WATER SUPPLY.—All water for domestic purposes is derived originally from the rainfall, but before reaching the consumer it undergoes numerous changes which materially alter its purity. As a source of direct supply rain water is only occasionally used, and generally only where no other source is available. If collected in the country it is the purest of all waters, but is not pleasant to taste. Upland surface water is rain water collected on a gathering ground and led into a reservoir, and is a very common source of supply. The purity of the water depends on the nature of the gathering ground, but as a rule it is a good water, and if carefully filtered is clear and wholesome. The water from surface wells and springs is used chiefly in isolated houses and small villages. The purity of the water is influenced by the depth of the well, the amount of pollution of the soil by organic matter, and the construction of the well itself. Shallow well water is always to be looked upon with suspicion, especially if the well is not properly steined. The water is as a rule cool and clear and pleasant to taste. The water from deep, or artesian, wells, is pure and sparkling, but may be hard (*q.v.*) Water is also obtained from rivers, and in London the water supply is chiefly from this source. If no sewage is allowed to enter a river, and if suitable filters are provided, such water is as a rule satisfactory; but if any sewage pollution exists, more especially at a short distance from the intake, the supply must always be looked on with suspicion. In times of flood also the water is highly charged with vegetable matter, and the usual filtration is not sufficient to render the water fit for drinking purposes.

FILTRATION OF WATER.—Artesian well water is supplied direct to the consumer, as it requires no filtration; but as a rule all other supplies to towns are filtered before distribution. The filtering medium is fine sand and gravel, the thickness of each layer varying according to the quality of the water to be filtered. The real filtering medium is, however, the fine scum which forms on the top of the sand, although a certain amount of oxidation takes place in the water in its passage through the layers. The amount of water passing through these layers varies very much, and opinions differ as to the permissible amount, the minimum being 5 gallons, and the maximum 25 gallons per hour through each square yard of surface. *See* FILTERS *and* FILTRATION. For domestic clarification of water there are numerous filters in use, such as the ordinary carbon filter, Bischoff's Filter, and Maignen's Filtre Rapide; but for true filtration either the Berkefeld or the Pasteur-Chamberland filter is necessary. *See* CARBON FILTERS. Water for drinking purposes must not be too hard, especially if such hardness is permanent and not temporary, the former being due to the presence of chlorides, sulphates, and nitrates of calcium and magnesium, and the latter to carbonates of calcium. Temporary hardness can be lessened by boiling and by the Porter-Clark process on a large scale. *See* CLARK'S PROCESS. Soft water is better

for washing purposes, not only because it uses less soap, but bcause it has no effect on the texture of materials, which undoubtedly a hard water has. The amount of water necessary for household purposes varies according as a house is supplied with water closets and baths or not. Without these 10 to 12 gallons per head per day are enough, but with them 20 to 25 gallons are necessary. In manufacturing towns over 30 gallons are required. Where water is derived from a public supply, a storage cistern becomes a necessity, and this should be large enough to contain sufficient water to supply the household for 24 hours, and should be in such a position that it can be easily cleansed. It should also be fitted with a close fitting cover, and should be cleansed at least once every six months. All houses should in addition be supplied with a draw off tap from the rising main. The effects of drinking impure water are very serious, as if such water is polluted with specific germs, epidemics may occur. The specific diseases most frequently caused are cholera and typhoid fever.

SITE AND STRUCTURAL ARRANGEMENT OF HOUSES.—Too much importance can hardly be given to the selection of a site for erecting a house. In large towns and, generally speaking, in places where houses are aggregated together, it is frequently impossible to make a selection; but arrangements can be made on nearly all sites to ensure a healthy dwelling. The first consideration is the nature of the soil. Houses erected on the hard primitive rocks should theoretically be the most healthy, the next being the gravels, followed by sandstone, and, lastly, clay soils. Roughly speaking, the more moisture contained in the soil the less healthy is the site; but other circumstances enter into the question which must be considered, more especially the question in gravel soils as to whether such soil is virgin or not, and whether it has been heavily manured or not. The manuring of land, useful and necessary for agricultural purposes, makes the site, at least for some time, not a desirable one, owing to the amount of decomposable organic matter in such manure. Land also which has been made up with house refuse, road slop, and other refuse, is a most undesirable site, and should never be used as such, at least until all such decomposable matter has been completely removed. The subsoil under all houses, with the exception of those built on hard rock, should be drained by means of open jointed pipes, and the water should either flow into a receptacle some distance from the house, into the nearest ditch, or, in towns, into the general drainage system, with the intervention of a proper and special disconnecting trap. In addition, the whole site should be covered to a depth of at least 6 in. with proper cement concrete, so as to prevent the entry into the house of ground air, or the air in the interstices of the soil. In the erection of a house in the country it is possible to take the aspect into consideration, the best aspect being either south-east or east, preferably the former. Bedrooms especially should face the south-east, and living rooms the north-west, thus ensuring that sunshine shall permeate all the rooms of the house. If a house faces south, then the rooms on the north side get no sun, while those on the south get too much. In the internal structural arrangements of a house, the points to be considered, in addition to those already dealt with, are the position of the water closets, the bathroom, cistern, and sinks. All these should be in such a position that the waste pipes can be taken at once outside. The cistern should be placed in the roof and should be readily accessible. The walls, whether built of stone or brick, should have a good damp proof course above the level of the ground. This should on no account be omitted, as if damp does occur when the house is built it is a difficult matter to insert it. The damp course may be composed of slate, Doulton's ventilating air bricks, or other impervious material. The space between the concrete and the under surface of the floor should be well ventilated, so that there may be a free current of air under the whole house. Neglect of this may be the means of giving rise to what is erroneously called "dry rot," which is due to the growth of a fungus. When once the fungus obtains a hold on the woodwork it is most difficult to eradicate, and it may eventually be necessary to remove all the woodwork before a cure is effected. The thickness of the walls of a house is regulated in London by the London Building Act; but the 9 in. wall, common in London, although satisfying the requirements of such Act if the building is less than 30 ft. high, and does not comprise more than two storeys, is not quite satisfactory from a sanitary point of view. Bricks do not by any means make an impervious wall, and to keep the house free from damp all the outside walls should be hollow. The hollow, which may be 1 or 1½-in. wide, may be filled with pitch or cement. The roof should be covered first with wood, then with felt, and then with slates or tiles. Roofs are frequently made with slates or tiles without wood or felt put underneath, but this makes the top rooms of a house cold in winter and warm in summer. There should be a ventilated air space between the ceilings of the top rooms and the roof itself, the ventilators being in such a position that they can be opened in summer and closed in winter. The size of the rooms in a house will depend largely on circumstances, but no room should be less than 8 ft. high or have a less capacity than 1,000 cubic ft. Every room should be provided with a window and fireplace, so as to ensure satisfactory ventilation. All pantries, larders, and rooms used for the storage of food should be dry, well lighted, and ventilated. Wire gauze at least ¼ in. gauge should be used in window openings to prevent the entrance of flies.

DISPOSAL OF THE DEAD.—Every year this question becomes a more serious one. In view of the fact that the average number of deaths every year in England and Wales during the last ten years is over 550,000, it will be seen that serious consequences might arise if the disposal of the dead were not carried out satisfactorily. In this country there are only two methods of disposal, *viz.* earth burial and cremation, the former being very much the more frequent. In the choice of a cemetery the important points to be considered are the nature of the soil and the necessity of sub-soil drainage. The best soil for a cemetery is a porous, gravelly, or sandy soil, while clay is the worst. The more porous the soil is the more speedily does decomposition set in, and the products of such decomposition are more quickly resolved into harmless elements. The grave should not be more than 9 ft. deep, and the whole graveyard should be drained to this depth. The drainage should be run into the nearest sewer, or if into a stream, care must be taken that the water from that stream is not used for drinking purposes. The Regulations of the Home Office state that there must be 1 ft. of earth above each coffin in a grave, and that it shall be at least 4 ft. below the surface of the ground. There is no doubt, however, that decomposition proceeds more rapidly the nearer the surface the decomposing material is, and a body say 18 in.

from the surface of the ground would possibly be more quickly destroyed than one 4 ft. To prevent any nuisance, however, the regulations have made the depth 4 ft., and the regulations also state that any grave is not to be opened except for the burial of members of the same family for fourteen years. The coffins should be made so that the natural process of decay can go on rapidly, and for this purpose they should be made of light and porous material, as wickerwork or ordinary pine. The use of oak, hard wood of all kinds, and especially lead coffins should be discontinued, as they only hinder the processes which must eventually take place. Vaults of any description should not be permitted. The more quickly the earth comes into contact with the body the better, and any means which retards this should not be allowed. In a clay soil decomposition may be retarded for years, and in some cases the substance known as adipocere is produced. Cremation means the destruction of the body by fire, and in a properly constructed crematorium this can be carried out in two hours without the production of a nuisance. Only one objection besides a sentimental one can be raised to this mode of disposal of the dead, and that is, that it is possible for death from poisoning to take place and the body afterwards cremated, thus leaving no trace of poison. This difficulty, however, can in nearly all cases be surmounted by the authorities insisting on a medical certificate of death signed by two medical practitioners instead of one, and of post mortems being insisted on in any suspicious cases.

Removal of Waste Matter. — The waste matter which must be removed from houses may be classified as follows: (1) Slop water, waste water from sinks and baths; (2) excreta; (3) house refuse. It is also necessary to make some arrangements for the collection of rain water. For the removal of slop water, etc., there must be either proper sinks and pipes connected with the drains or cesspools, or the slop water can be collected in pails and thrown over the land. Excreta may be disposed of by means of water closets connected to the drains or cesspools, or the dry earth system may be adopted. House refuse is either collected by the sanitary authority or may be disposed of by the householder on adjacent land.

Sewerage and Drainage. — In towns and villages with a sewage system adequate means of drainage can be provided by means of proper pipes, traps, and connections. Sanitary authorities are empowered to make byelaws which shall state the size, fall, nature of traps, material, and means of ventilation of such drains. Every drain must be of adequate size, and must be constructed of stoneware or cast iron pipes. The diameter of the drain pipe will depend on the size of the house, but must be at least 4 in. For an ordinary house of six or eight rooms with bathroom this diameter is sufficient, but in larger houses it is necessary to use pipes with a diameter of 6 in. The drain must have a sufficient fall to the sewer, and this fall ought to be equal on the whole length of the drain. A 4 in. drain should have a fall of 1 in 40, a 6 in. drain of 1 in 60, and a 9 in. drain of 1 in 80 at least; but it is very desirable to have more than the above. A useful formula to remember is that each length of 2 ft. pipe should have a fall of half an inch, which is equal to a fall of 1 in 48. This amount of fall renders the drain self-cleansing. The whole of the drains must be laid on a bed of concrete 6 in. thick, and in a 4 in. drain 12 in. broad, and a 6 in. drain 18 in. broad. The drain should also be covered with concrete. With cast iron pipes it is not necessary to use concrete on the top, but the pipe should be laid on a concrete bed. The joints of cast iron pipes should be at least 2½ in. in depth, and made with molten lead, properly caulked. The joints in stoneware pipes must be made with cement. All drains should be tested with water, and should be able to withstand a pressure of at least 2 ft. head of water. Where necessary proper traps must be provided, the most important of these being the intercepting trap between the drain and the sewer. This should be placed in a manhole as near as possible to the main sewer, and should be self-cleansing. The trap must be provided with a cleansing eye and stopper, so that if necessary that part of the drain to the sewer can be cleansed. All rain water pipes should discharge over trapped gullies. The soil pipe must be constructed either of solid drawn lead or of heavy cast iron. The former should only be used if the soil pipe is inside the building. For a 4 in. drain pipe the lead should weigh not less than 74 lb. per 10 ft. length, and for an iron pipe the weight should be 54 lb. for every 6 ft. length, and should be $\frac{3}{16}$ in. in thickness. The lead pipe should have proper wiped plumber's joints, and the iron pipe should have socket joints made with lead properly caulked. The soil pipe, which must be 4 in. in diameter, should be continued upwards to a height of at least 3 ft. above the roof, and as far as possible from any windows or openings into the house. All pipes from sinks and baths should be of lead, efficiently trapped by a syphon trap, and the liquid from them should discharge into a trapped gully. All joints of these lead pipes must be proper wiped joints and not slip joints. The drain itself must be ventilated by means of an air inlet, which is generally placed at the manhole in front, and by outlets, one of which may be the continuation of the soil pipe and the other a special pipe 4 in. in diameter at the highest point of the drain. Traps are of various kinds, but the simplest is the ordinary syphon trap at the outgo of sinks. It is made by bending the lead pipe like the letter S, the lower bend of the letter forming the water seal. Numerous varieties of traps are on the market of a satisfactory character, but the old fashioned dip traps, bell traps, lip traps, and D traps must not be used. The waste pipes from kitchen sinks frequently become offensive, owing to the deposit of greasy matter in the interior. The best way of avoiding this is to use plenty of hot water and to occasionally cleanse with hot water and a strong alkali, as carbonate of soda crystals.

Water Closets.—In recent years great improvements have taken place in the construction of water closet apparatus. The patterns of closet pans and traps now recommended are of much simpler construction, are easier cleansed, and do not readily get out of order. These should be constructed of earthenware, the pan being of such shape and capacity that all excreta shall fall directly into the trap, which is to be an efficient syphon trap and must have sufficient seal, so that sewer gas cannot find its way into the water closet itself. There are numerous forms of water closet apparatus in the market which comply with the above principles, but there are still a number of closet apparatus in use which do not. The following are some of the apparatus in use: Valve closets are good closets if used carefully and if of good type. They require a flush of at least three gallons of water, and, as the apparatus is complicated, are apt to get out of order. Washout closets were at one

time much used, but are not satisfactory. Washdown closets are the best, and variations of this type are numerous. By far the great majority of closets erected have washdown pans and traps. The old hopper closet with spiral flush may still be seen, but this pan is very difficult to cleanse, and in poor class property is a continual source of nuisance. The short hopper pan with rim flush is quite a satisfactory closet for ordinary use, and is cheap and easily cleansed. The junction between the stoneware trap and the iron or lead soil pipe must be properly made with Portland cement if the soil pipe be of iron, and if of lead a flanged brass thimble must be inserted, the joint between the thimble and the stoneware being made with Portland cement, and between the lead and brass there must be a wiped or overcast metallic joint. If an iron pipe is joined to a lead pipe, there should be a brass thimble, and the joint should be made of lead and properly caulked. If one closet discharges into the same soil pipe as another at a lower level, an anti-syphonage pipe must be inserted to prevent the unsyphoning of the trap of the water closet. Such pipes are, as a rule, about 2 in. in diameter, and are taken from the top of the traps of the water closets and connected with the soil pipe above the higher water closet. Water closets are flushed either from a large cistern with check valve or by means of a small water waste preventing cistern of a capacity of 2 or 3 gallons. The former is now only used with valve closets, and the latter to all other kinds of water closets. These cisterns are of various patterns, and act by displacement or syphonage. Needless to say, no water closet should be supplied direct from the main without the intervention of a cistern, and no water closet should be supplied from the same cistern that supplies water used for drinking purposes. Trough closets, although at one time popular for schools, are now being done away with, as they are difficult to keep clean. Slop closets, where slop water is collected in a tank and made to discharge automatically, are used in some provincial towns; but, except that there is a saving of water, there is no other advantage. When no sewage system exists, the drains may discharge into a cesspool, which should be quite impervious and situated as far as possible from the house. It should also be cleansed periodically, and the rain water from the house should be collected separately, otherwise the cesspool will require very frequent emptying. In the dry system of removal of excreta, earth closets, pail closets, or midden privies are used, but these require careful supervision, so as to prevent nuisance. Earth closets are the most satisfactory if supplied with dry garden mould. The contents of these may be used in the garden for manure, or, if in town and collected by the sanitary authority, may be mixed with a certain proportion of ashes and sold to farmers for manure. HOUSE REFUSE consists of ashes from fires, vegetable and animal refuse, sweepings from rooms, etc. The best way to get rid of a large proportion of this is for each householder to burn his own refuse, which can easily be done in a modern kitchener grate, leaving only dry ashes, which may be utilised in the garden. This in most cases is not, or cannot, be done, and consequently a large expenditure is required in towns to remove such refuse. The refuse must be kept in a proper dustbin and covered, and should be removed at least once a week. In flats and tenement dwellings daily removal is a necessity. After collection such refuse is used either to make up low-lying land, used as a manure, or burnt in a destructor, the clinkers formed being used to make up roads, etc.

SEWERS.—Main sewers which carry off the water from house drains vary in size from 9 in. to 10 ft. Pipes are used if the diameter is not more than 18 in., but above that brick sewers are necessary, and these ought to be oval in section. The rate of flow in sewers should not be less than 2·5 ft. per second, and to ensure this the sewers should have a fall of 1 in 200 for 12 in., to 1 in 750 for a sewer 5 ft. in diameter. These sewers must be ventilated every 100 yards, and there may be either manholes in the centre of the roadway or pipes may be laid from these to shafts about 30 ft. high against buildings if possible. Various methods have been tried to abate nuisances from these ventilators, but none have so far proved very successful under all circumstances. One of the most successful is Reeves' system, where deodorisation certainly takes place by means of the production of free oxygen. The following formula given by L. Parkes is used to calculate the discharge for a sewer:

$V = 55\sqrt{D \times 2F}$, and $Q = V \times A$.
V = Velocity in feet per minute.
A = Sectional area of current in square feet.
D = Hydraulic mean depth.
F = Fall in feet per mile.
Q = Cubic feet of water discharged per minute.

SEWAGE DISPOSAL.—The methods adopted are: (1) Discharge of sewage into the sea or the nearest stream either in a crude state or after previous treatment by filtration, subsidence, or a combination of both with chemicals. (2) Discharge of sewage on land either by irrigation or by intermittent downward filtration. (3) Purification by means of septic tanks, the effluent being discharged into the nearest stream or into the sea. The first method is the one most frequently adopted, as, if there is no previous treatment of the sewage, it is probably the cheapest. The following are some of the patent processes:

Scott's . .	Lime and clay.
Sillar's A.B.C. .	Alum, blood, clay, and charcoal.
Coventry process	Alum, iron, and lime.
Anderson's. .	Crude sulphate of alumina.
Acton process .	Ferrozone and polarite.
Amines' . .	Lime and herring brine.

The SEPTIC TANK SYSTEM (*q.v.*) has only recently been put in operation, and, so far, in smaller towns has proved satisfactory. From a sanitary point of view it is the least satisfactory system. The disposal of sewage on land, if properly carried out, is the best; but this is only possible where suitable land can be had at a reasonable distance. SEWAGE FARMS, as they are called, have proved fairly successful, and, with the exception of cereals, crops such as rye grass and root crops can be grown satisfactorily. If chemicals are used, there is always a difficulty in disposing of the sludge, which has little or no manurial value. The chemicals used are alum; lime, either alone or in combination with phosphate of calcium or clay. The difficulties in dealing with sewage will be very much lessened if no rain water is allowed to discharge into the house drains, and this separate system has been adopted in several towns.

DISINFECTANTS AND DISINFECTION: Many diseases are caused by germs or bacteria, and it is necessary after the occurrence of one of these diseases for disinfection to be carried out to prevent further infection. Popularly, the term disinfectant is applied to a large number of substances which do not destroy such bacteria, and it is therefore necessary to clearly

distinguish between deodorants, antiseptics, and true disinfectants. DEODORANTS only destroy any offensive odour; ANTISEPTICS merely arrest the growth of germs; while true DISINFECTANTS absolutely destroy the germs, so that they become harmless. Numerous chemicals are used for disinfecting purposes, but only very few are true disinfectants, and in nearly all cases these are very poisonous salts. The most commonly used are corrosive sublimate, carbolic acid, and preparations of creosote; and to these may be added chinosol, a synthetic product. For ordinary use carbolic acid in a solution of 5 per cent. (1 in 20) is satisfactory; but this strength has a very deleterious action on clothing and bedding, and the same applies to most of the creosote preparations. Corrosive sublimate in the strength of 1 in 1,000 is a good disinfectant, but it is not advised, as it is extremely poisonous and destructive. Permanganate of potash, 5 per cent., is also a useful disinfectant, but in this strength is not suitable for disinfecting clothing. Chlorinated lime, or chloride of lime, as it is popularly called, in 5 per cent. solution, is a useful disinfectant, but has itself a disagreeable odour. The best and most satisfactory method of disinfecting bedding and clothing is by means of steam in a closed chamber, and all sanitary authorities should possess a suitable steam disinfecting apparatus. Washington Lyons' apparatus consists of a cylinder with a double casing or jacket. Steam is first introduced into the jacket, thus preventing loss of heat by condensation. The goods to be disinfected are placed in the chamber, and a door, which is lined with rubber seating and secured by screw clamps, is closed. Steam is then admitted to the chamber until the pressure reaches about 20 lb to the square inch, giving a temperature of about 260° F. The steam is superheated by having the pressure in the jacket higher than in the chamber itself. The articles are kept in the chamber for about ten minutes before the steam is allowed to escape. The door at the other end of the chamber is then opened and the goods removed. The whole apparatus is constructed so that when *in situ* one door opens into one room and the other into another, thus ensuring that the goods when disinfected shall not again come into contact with other infected articles. Other disinfectors are Thresh's, Reck's, and the Equifex, made by Defries & Co. In any of the above apparatus, if ordinary precautions are taken, no damage need be done to ordinary bedding, blankets, and wearing apparel. Leather and furs cannot, however, be disinfected by steam, but may be by dry heat cautiously applied. Articles which have previously been exposed to sulphur fumigation should not be disinfected by steam, because sulphuric acid is formed, and consequent destruction to the material ensues. It is also to be remembered that steam acts as a mordant, and permanently fixes any stains such as those caused by albuminous material, blood, food, or urine.

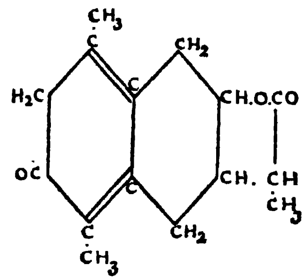
FUMIGATION: In addition to disinfection of bedding, clothing, etc., by steam, it is advisable in cases of infectious disease to fumigate the room, and this may be done either by means of sulphur or formalin. The former is better if the room is infected with vermin, as the latter has no effect on these; but in the majority of cases formalin is the most satisfactory agent to use. The strength of sulphur is usually 1 lb. to every 1,000 cubic feet of space, while in the case of formalin 25 to 30 formalin tablets are necessary for the same space. Formalin has no deleterious action on brass, delicate fabrics, or colours; while sulphur, especially if there is any moisture present, may injure these substances. After fumigation the room should be freely ventilated, and sunshine should be allowed to permeate the whole room if possible. The walls, ceiling, and floor of the room may be sprayed with a 40 per cent. solution of formalin, and the wall paper should always be stripped off. This is more especially necessary after cases of scarlet fever and diphtheria. For a more complete study of the subject the following works on hygiene may be consulted: Stevenson and Murphy (3 vols.), Hamer, Louis Parkes, Whitelegge, and Wynter Blyth.—P. C. S.

Sanserif (*Typog.*) A letter without serifs, as M.

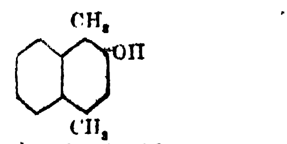
Santalum (*Botany*). An East Indian tree, *Santalum album* (order, *Santalaceæ*), yields SANDAL WOOD (*q.v.*)

Santonin (*Botany*). A powerful drug prepared from the dried immature capitula (or flower heads) of *Artemisia maritima* (var. *Stechmannia*; order, *Compositæ*).

Santonine (*Chem.*) Probable formula

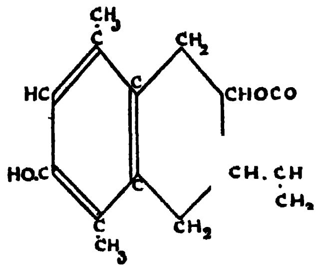


Forms white shining leaves or trimetric tables: melts at 170°; 1 part dissolves in 5,000 parts water at 17·5°, in 250 parts at 100°; much more soluble in alcohol: easily soluble in chloroform; its solutions are lævorotatory. The optically active forms show triboluminescence. It is used in medicine for round worms and threadworms. Poisonous: an overdose affects the vision, causing objects to appear violet, greenish, then yellow. It occurs in wormseed (the unopened flower heads of various kinds of Artemisia). The wormseed is treated with a thick milk of lime, water added and violently shaken; the calcium santoninate is extracted at 65° to 70° with alcohol; and the alcoholic solution decomposed with hydrochloric acid. The crude santonine is purified by recrystallising from alcohol, using animal charcoal first to decolorise it. It must be dried in absence of light. Santonine is the lactone of santoninic acid; it is also a ketone, as it forms both a hydrazone and an oxime. That it contains a naphthalene ring and a three carbon atom side chain is shown by the fact that santoninic acid and other acids derived from santonine yield dimethyl-β-naphthol and propionic acid—

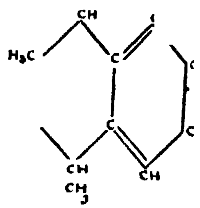


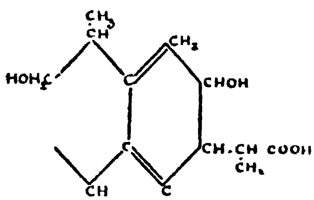
and CH_3CH_2COOH, when fused with caustic potash. When santonine is exposed to light it turns yellow, forming an isomeric compound called chromosantonine. Another isomer of santonine known as desmotroposantonine is formed when santonine

dissolved in concentrated hydrochloric acid is allowed to stand. When purified by washing with hydrochloric acid and recrystallisation from alcohol it forms shining needles, which melt at 260°, and are not changed by light; neither does it yield an oxime or a hydrazone; but it yields an acetyl derivative. It is probably the enol form of santonine:



When light acts on a solution of santonine in dilute acetic acid, Photosantonic acid is formed; when light acts on its solution in dilute alcohol, Isophotosantonic acid is formed. The fomulæ of these substances are respectively





Sap (*Botany*). A general term for the fluids contained in the tissues of a plant; the circulating fluids which convey nutritive material.

—— (*Met.*) The unaltered core of iron in the bars of blister steel, made by the cementation process at "spring heat."

Saponification. Generally in a technical sense means the chemical changes which result when soap is made by the action of alkali on fixed oils or fats; but it also includes other changes in which compound ethers are broken up. At one time the term was confined to the action of alkalies (including lime), but it now includes the agency of sulphuric acid, superheated steam, and enzymes peculiar to certain seeds. *Cf.* HYDROLYSIS.

Saponine (*Chem.*) A glucoside. It is a white amorphous powder soluble in water, and having the property of giving a lather to water when shaken. It occurs in many plants, and especially in the common soapwort. Hydrolysed by dilute acids to glucose and a crystalline substance sapogenin, constitution unknown.

Sapphire (*Min.*) The blue variety of Corundum (*q.v.*) The ordinary sub-variety is known as Oriental Sapphire; that with a reddish or bluish reflection is called Girasol Sapphire; and the sub-variety with a pearly reflection is the Chatoyant or Opalescent Sapphire. The chief localities for Sapphires are Ceylon, Pegu, Bohemia, near Expailly in France, and New South Wales. It is highly prized as a gem stone.

——, **Brazilian** (*Min.*) This is a blue variety of Tourmaline (*q.v.*); the colour is lighter than the true sapphire, and the stone is less hard. *See* PRECIOUS STONES.

Saprophyte (*Biology*). An organism which subsists on decaying organic substances.

Sap Wood (*Botany*). The new wood next to the bark of a tree. It is inferior in value to the heart wood, from which it is usually easily distinguished by colour, etc.

Saracenic (*Architect.*) The architecture of various countries during the period in which they were under the influence of the faith of Islam. It can be divided into Arabian, Moorish, Persian, Indian, and Turkish. These styles, though differing in many respects, have much in common. *See* MOORISH.

Sarcine (*Chem.*) HYPOXANTHINE (*q.v.*)

Sarcolactic Acid (*Chem.*) *See* LACTIC ACID.

Sarcosine (*Chem.*)

$$\begin{array}{l} CH_2NHCH_3 \\ | \\ COOH \end{array} \quad \text{or} \quad \begin{array}{l} CH_2.NH_2CH_3 \\ |\qquad\quad | \\ CO{-}O \end{array}$$

(Methylglycocoll.) Rhombic prisms; melts at 210° to 220°, with decomposition into carbon dioxide, dimethylamine, and other products; soluble in water; heated with soda lime it forms methylamine; acts as a weak base; forms characteristic platinum double salt. It is a decomposition product of creatine (*q.v.*); also formed by boiling caffeine with baryta water. It is prepared synthetically by the action of monochloracetic acid on methylamine:

$$\begin{array}{l} CH_2Cl \\ | \\ COOH \end{array} + H_2N.CH_3 = \begin{array}{l} CH_2NHCH_3 \\ | \\ COOH \end{array} + HCl$$

Sard (*Min.*) An orange brown variety of CHALCEDONY (*q.v.*)

Sardonyx (*Min.*) A variety of Chalcedony having parallel banding of alternate layers of red and bluish white or white. *See also* PRECIOUS STONES.

Saros (*Astron.*) *See* ECLIPSES, NUMBER OF.

Sarsaparilla (*Botany*). Is the dried roots of *Smilax officinalis* (order, *Liliaceæ*), and other species of Smilax imported from Tropical America and the East Indies.

Sash (*Carp. and Join.*) The portion of a window containing the glass.

Sash Bit (*Carp. and Join.*) A long twist bit used for boring sashes.

Sash Door (*Carp. and Join.*) A door having the upper part glazed.

Sash Frame (*Carp. and Join.*) A term sometimes applied to a SASH (*q.v.*), but more properly restricted to the outer frame of a window in which the sashes move.

Sash Tool (*Dec.*) A small brush made of hog bristles, used for painting window sashes. *See* PAINTERS' BRUSHES.

Satarra (*Woollen Manufac.*) An old type of woollen cloth, with fine lines weftways.

Sateen (*Textile Manufac.*) A form of weave used for cotton, woollen, or linen fabrics. Very largely adopted for cotton cloths requiring dyeing, printing, or mercerising. It has a very solid and smooth surface, like satin, of either warp or weft. The effect is produced by the rearrangement and regular distribution of the intersections in such a way that they are hidden from view. A WARP SATEEN is a cloth with a warp surface and a greater proportion of warp threads than weft; WEFT SATEEN is the reverse.

Satellite (*Astron.*) A term applied to the smaller bodies revolving round the planets or stars. Thus the Moon is the satellite of the Earth.

Satin. A plain silk fabric presenting an even, lustrous, soft surface, obtained by the long flushing or floating of the warp threads on the face of the work.

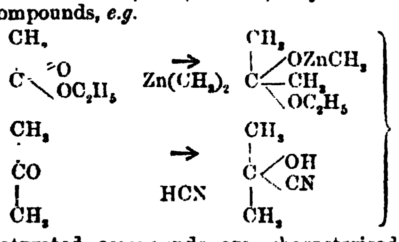
Satin Leather (*Leather Manufac.*) Leather finished with bright black polish to resemble satin. It is finished quite smooth, without grain marks.

Satin Spar (*Min.*) This term is used for the finely fibrous varieties of Calcite, Aragonite, or Gypsum; in all three cases the mineral is in veins with the fibrous structure running transversely. All are white or greyish white (rarely pink in the case of Gypsum), and show a satin-like surface when polished.

Satin Walnut. *See* WOODS.

Satin Wood. *See* WOODS.

Saturated Compounds (*Chem.*) Compounds in which each element is united to monovalent atoms or groups of atoms, the number of which equals the maximum valency of the element. Thus if oxygen is regarded as divalent, then water is a saturated compound; but if oxygen is regarded as tetravalent, then water is an unsaturated compound and should form additive compounds; a very large number of compounds crystallise with one molecule of water. On the above definition, acetic acid and all compounds containing a carbonyl group must be regarded as unsaturated, and, in fact, they all form additive compounds, *e.g.*



Saturated compounds as regards carbon.

Saturated compounds are characterised by their inability to enter into reaction unless an atom or atomic group, or more than one atom or atomic group, can be replaced by another atom or atomic group. Thus marsh gas can only react by having one or more hydrogen atoms replaced by other atoms.

Saturated Steam. Steam in the condition of a saturated vapour; a diminution of volume without change of temperature (*i.e.* isothermal compression) or a fall in temperature causes condensation to commence. *See also* VAPOUR PRESSURE *and* STEAM.

Saturation (*Heat*). A term applied to the condition of a vapour when it is at the maximum density and pressure which correspond to its temperature; condensation commences if the vapour be compressed, the pressure remaining constant. *See* VAPOUR PRESSURE.

——, **Magnetic.** When a magnet has been magnetised as strongly as possible, it is said to be SATURATED; the material of the magnet becomes less and less permeable as the magnetising force is increased, and the total number of lines of force which can be caused to pass through the iron thus tends towards a limit. In good wrought iron this limit is practically reached when the value of the magnetic induction B is about 20,000 lines per square centimetre; in cast iron the number is about 12,000. Higher values have, however, been obtained in laboratory experiments.

Saturation of the Air (*Meteorol.*) When the atmosphere contains so much moisture that it cannot carry any more it is said to be saturated.

Saturn, Planet (*Astron.*) Remarkable for possessing what appear to be three flat rings surrounding the planet; round the outside of these rings move eight satellites. Distance from sun, 886,000,000 miles. Diameter, 73,500 miles. Periodic Time, about 29½ years.

Saunders Blue (*Paint*). The term is a corruption of the French *Cendres Bleues*. Ultramarine ash.

Savannah. A plain or tract of land devoid of trees, but covered with other forms of vegetation.

Saw. *See* SAWS.

Saw Bench. The table or support of a machine saw, on which rests the material that is being cut. The term is most commonly applied to the table of a circular saw.

Saw Block (*Typog.*) A piece of wood similar to a carpenter's mitre block, with the addition of a right angle cut, on which furniture is cut to required lengths.

Sawdust. This is used for various cleaning purposes; for mixing in certain patent fuels; in moulding, to give porosity to the moulds; as a packing material, in the manufacture of oxalic acid, and for various other purposes in the arts and trades.

Saw File. A file specially made for sharpening saws. The commonest type is of triangular section, but files of other shapes are also used for sharpening special kinds of saws.

Saw Filing Machine. A machine used for sharpening large saws, such as band saws. The saw is fixed in a suitable holder, and files moved by the machine act upon the teeth in succession.

Saw Frame (*Carp., Eng., etc.*) A frame in which a thin or narrow shaped saw is fixed, being kept in tension by the frame. Hack saws and bow saws, fret saws and certain forms of machine saws are thus supported. *See* SAWS.

Saw Gullet. The space between two teeth. This space has to be enlarged by filing, as the teeth wear away through repeated sharpening; the process is termed GULLETING.

Sawing In (*Bind.*) Making slight indentations in the back of a book previous to sewing the sections together. The indentations are for the purpose of receiving the cords or bands (*q.v.*) to which the book is sewn, and are made by a tenon saw or a machine. In the case of *flexible binding* the back of the book is not sawn, the bands lying outside. *See* SEWING.

Saws (*Carp. and Join. Eng., etc.*) Saws may be divided into two main classes: (1) those used by hand, and (2) those driven by machinery. Of the first class, the HAND SAW is the most important; the blade is about 2 ft. long, sufficiently thick to ensure stiffness when in use, tapering in form, and having from 5 to 7 teeth to the inch. Of the same type are the RIP SAW, with large teeth, for cutting along the grain of wood, and the HALF RIP (these have 3 or 4 teeth to the inch); and the PANEL SAW, used in cutting tenons, etc., and having from 7 to 10 teeth per inch. CROSS CUT SAWS have a blade slightly curved or bellied along the cutting edge, and a handle at each end, requiring two operators; they are used in felling trees and in cutting across large balks and logs. For cutting across the grain of wood in small work the TENON SAW is used. The blade is very thin, and is stiffened by a rib or back of brass or steel; from this fact the term BACK SAW is sometimes applied. It has 10 or 12 teeth to the inch. A DOVETAIL SAW is a similar saw with still finer teeth, usually 14 to 18 per inch. For cutting along a curve or in a very narrow space, a saw with a very narrow tapering blade (without a back) is used; of this form are the COMPASS SAW, PAD SAW, and KEYHOLE SAW. When the blade is very narrow or very thin, it does not possess sufficient strength to enable it to be used without breaking, and is therefore supported in a frame, by which the blade is kept in tension and thereby prevented from sudden bending and consequent breakage. The BOW SAW is the type most used, in which the saw is fixed in a rectangular hinged frame of wood, and kept in tension by a twisted cord. A FRET SAW for hand use also has a rectangular frame, but made of steel, and the fine saw is kept sufficiently tight by the elasticity of the frame itself. A HACK SAW usually has a blade ⅝ or ½ in. wide, kept in tension in a metal frame; it is used for sawing metal, the blade being of hard tempered steel. Hack saws are not usually sharpened, as in most cases the blade breaks before its cutting power is exhausted, and a new blade is fitted.

The most important types of MACHINE SAW are the CIRCULAR SAW, BAND SAW, and JIG SAW, or JIGGER. The former is a circular disc of steel, varying in diameter from a few inches to several feet, according to the use for which it is required. The most important application of the circular saw is the cutting of logs and balks into deals, boards, etc., but some types are used for cross cutting. A GROOVING SAW is a circular saw having a thick blade projecting a small distance only above its table, and is used for rapidly cutting long grooves in wood. A BAND SAW is wholly distinct from all the preceding types. It consists of a long ribbon of steel, having teeth on one edge, the ends being brazed together to form an endless band. This band runs over revolving pulleys, so that the motion of the teeth is always in one direction; it has a great variety of uses, and is especially useful in rapidly cutting curved work. Band saws may be adapted for cutting metal as well as wood. A JIG SAW consists of a narrow straight blade, fixed in a frame, by which it is kept in tension; this frame is given a reciprocating motion by machinery. Two or more blades are often fixed in one frame, and the saw is then used for cutting simultaneously a number of boards from a single deal or log. Fret saws and hack saws are occasionally driven by machinery, a fret saw driven by foot power being a familiar tool in the workshops of amateurs. Various other types of machine driven saws are also made for special uses, but they usually follow one or other of the above types.

Saw Setting. If the teeth of a saw lay entirely in the plane of the blade, the saw would jam in the cut or kerf. To prevent this, the teeth are bent alternately to right and left by means of pliers, a punch, or a tool with slots fitting the teeth, termed a SAW SET.

Saw Sharpening. The formation of the cutting edge on the teeth of a saw, as distinguished from setting and gulleting.

Saw Spindle. The axis or shaft on which a circular saw is mounted and by which it is driven.

Saw Table. A SAW BENCH (*q.v.*)

Saxhorn (*Music*). A family of brass wind instruments invented by M. Sax, a Belgian, about 1840. *See* p. 437.

Saxifragaceæ (*Botany*). An order which includes the genus RIBES, the Currants (*R. rubrum*, the Red Currant; *R. nigrum*, Black Currant; *R. grossularia*, Gooseberry), and a number of garden plants.

Saxon Architecture. *See* ANGLO-SAXON ARCHITECTURE.

Saxophone (*Music*). A family of brass wind instruments invented by M. Sax, and played by means of a single reed. *See* p. 432.

Sc (*Chem.*) The symbol for SCANDIUM (*q.v.*)

Scab (*Foundry*). A place on the surface of a casting where the fluid metal has penetrated the surface of the mould, forming a lump or projection, which may be composed either of sound metal or of metal mixed with sand, and consequently unsound.

Scabbard (*Arm.*) The sheath of a sword. *See* ARMOUR.

Scabbling (*Build.*) Roughly reducing stones (at the quarry) to the desired shape.

Scabby (*Typog.*) A term used to describe work unevenly printed, owing to irregular distribution of ink and consequent patchy appearance.

Scabellum (*Architect.*) A form of pedestal used as a support for a bust or statue.

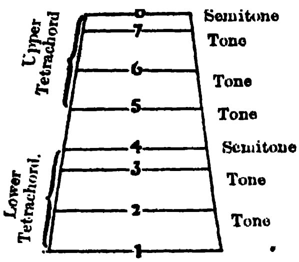
Scagliola (*Dec.*) An imitation marble composed of the same materials as MAREZZO (*q.v.*); but the process of manufacture is somewhat different.

Scalar Quantity (*Phys.*) A quantity which possesses magnitude, but not direction, as distinguished from a VECTOR (*q.v.*) Mass and density are examples of scalar quantities.

Scale (*Drawing, etc.*) (1) A line (straight or curved) which has been divided in some special manner. (2) A piece of wood, metal, ivory, etc., on which such a scale is drawn. (3) The ratio of the dimensions of a drawing to the corresponding dimensions of the actual object which it represents. *See* SCALE DRAWING.

—— (*Music*). The series of sounds into which an octave is divided. Scales are of two kinds: Diatonic and Chromatic. The DIATONIC SCALE, so called because in performing it the passage is chiefly *through tones*, is of Greek origin, and of two kinds or modes: (1) The Major mode; (2) The Minor mode. The MAJOR MODE consists of two Tetrachords

having the same steps, viz. Tone, Tone, Semitone; and are themselves separated from each other by a Tone. The steps therefore are:



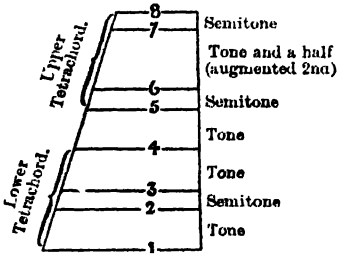
all the intervals being Tones excepting between the 3rd and 4th and between the 7th and 8th sounds, which are Semitones. Because there are between the 1st and 3rd sounds two tones (a Major 3rd), this mode is called the Major Diatonic scale. If C is taken as the starting note to form these steps, the first tetrachord will consist of C, D, E, F, the separating Tone reaching to G, and the second tetrachord consisting of G, A, B, C—all natural notes. Hence this is sometimes called the Natural scale. But if any other note than C be taken as a starting point, sharps or flats (*q.v.*) are required; *e.g.* taking B as a starting or keynote, the first tetrachord is—

| Tone | Tone | ½-Tone |
B C♯ D♯ E

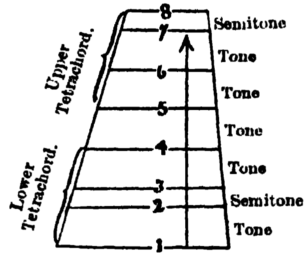
and the second tetrachord—

| Tone | Tone | ½-Tone |
F♯ G♯ A♯ B.

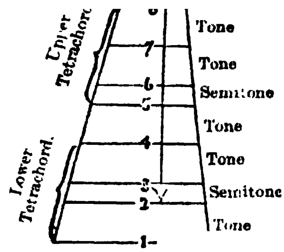
These sharps and flats are placed at the beginning of a piece, and are known as the key signature. For the sharps and flats necessary to each Major scale *see* KEY SIGNATURE (p. 332). The MINOR MODE originally consisted of the same sounds, starting a minor 3rd lower, *i.e.* taking the sixth note as the starting note. Modern music discards this Normal minor mode, except in the case mentioned below, but recognises two forms of the Minor mode: (*a*) The Harmonic form, and (*b*) the Melodic form. (*a*) The Harmonic form, as its name implies, is that employed by parts in progressing from one chord to another, and is the older of the two forms. It only differs from the original minor in having the seventh sound sharpened so as to give a proper leading note, *i.e.* a seventh sound of the scale a semitone only below the eighth. The order of the steps in the Harmonic form of the minor are:



(*b*) To avoid the awkward interval of the augmented second when taken melodically, the Melodic form of the minor scale came into practice, which gives the following order of steps in ascending:



This, however, with the exception of the third sound, is identical with the Tonic major (*q.v.*); and in order to preserve the identity of the Minor mode, the steps of the upper tetrachord are altered in descending to the Normal minor, the order of the steps being:

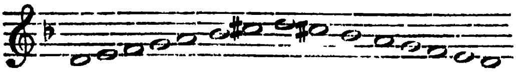


The CHROMATIC SCALE consists entirely of semitones, the octave being divided into twelve steps. There are two forms of the chromatic scale, *viz.* the Harmonic and the Melodic, the difference being one of notation only. The Harmonic form in the Major key consists of the seven notes of the Major diatonic scale with the Minor 2nd, 3rd, 6th, and 7th, and Augmented 4th added; in the Minor key it consists of the seven notes of the Normal minor scale with the Minor 2nd, Major 3rd, 6th, and 7th, and Augmented 4th added. The melodic form of Chromatic scale in the Major key consists of the seven notes of the Major scale, with the addition of a chromatic semitone after the 1st, 2nd, 4th, 5th, and 6th notes in ascending, and, in descending, is identical with the Harmonic Chromatic scale. In the Minor key it consists of the Normal minor scale, with a sharp (or natural) inserted after the 1st, 3rd, 4th, 6th, and 7th notes when ascending, and having exactly the same notes in descending, with the single exception that the Minor 2nd of the key is used instead of the chromatically altered keynote. The following shows the different scales, taking D as the keynote in each case:

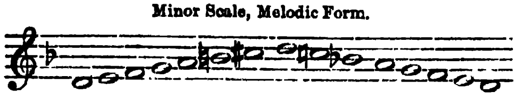
Major Diatonic Scale.

Minor Scale, Normal Form.

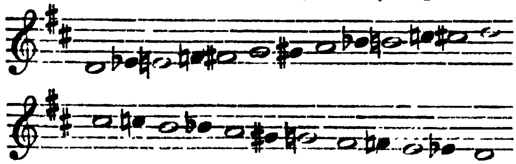
Minor Scale, Harmonic Form.



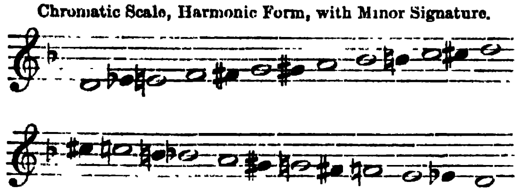
Minor Scale, Melodic Form.



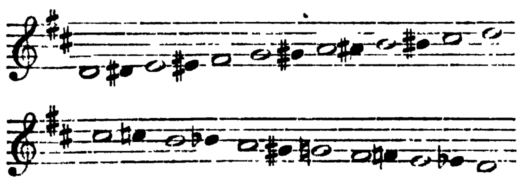
Chromatic Scale, Harmonic Form, with Major Signature.



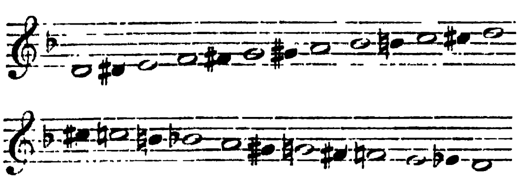
Chromatic Scale, Harmonic Form, with Minor Signature.



Chromatic Scale, Melodic Form, with Major Signature.



Chromatic Scale, Melodic Form, with Minor Signature.



It is not unusual to find incorrect notation in chromatic scales, the reason being that at times it minimises the number of accidentals in a passage. The ancient scales of the Church are shown under MODES (*q.v.*) *See also* KEY *and* KEY SIGNATURES.

Scale (*Trade Term*). (1) Material formed on the surface of an object, *e.g.* oxide formed on wrought iron during forging. (2) Material which has been carried into boilers or tanks suspended or dissolved in the water, and has been deposited on the walls or plates of the vessel.

Scale Board (*Typog.*) An obsolete term describing a material formerly used for obtaining accurate register (*q.v.*) Leads and thin strips of cardboard are now generally employed.

Scale Drawing. Drawing an object to scale means making a drawing in which all the dimensions are altered in the same proportion; the ratio of the actual size of the drawing to the actual dimensions of the object is termed the REPRESENTATIVE FRACTION, or the SCALE, of the drawing.

Scale of Hardness (*Min.*) *See* HARDNESS.

Scale, Thermometric (*Heat*). The division into convenient intervals, termed DEGREES, of a known difference of temperature. This difference is in practice that between the freezing and boiling points of pure water at normal atmospheric pressure. In the scale used in scientific work, the CENTIGRADE SCALE, the two fixed points, as the above two temperatures are called, are marked 0° and 100° respectively; in the English, or FAHRENHEIT SCALE, they are marked 32° and 212°, and in the REAUMUR they are marked 0° and 80°. Thus 100° Centigrade corresponds to 180° Fahrenheit and 80° Réaumur. For conversion from one to another it is convenient to use the following formula, in which F denotes the reading on the Fahrenheit, C the Centigrade, and R the Réaumur scales:

$$F - 32 = \frac{9}{5}C = \frac{9}{4}R.$$

Scaling (*Eng., etc.*) Removal of scale or deposits from a surface, *e.g.* from the inner surface of the plates of a boiler.

Scaling Hammer (*Eng.*) A hammer with a sharp edge, used for SCALING (*q.v.*)

Scandinavian (*Typog.*) A printing machine of the platen principle.

Scandium (*Chem.*) Sc. Atomic weight, 44. A very rare metal occurring in gadolinite and euxenite. The metal has not been obtained. Oxide, Sc_2O_3, a white infusible powder. Sulphate, $Sc_2(SO_4)_3$, forms a double salt with potassium sulphate. Spectrum (spark) is characteristic and very complex. The existence of scandium was predicted by Mendeleeff, and he gave it the name Ekaboron.

Scantling (*Build., etc.*) (1) A sample or pattern, *i.e.* a small quantity. (2) The dimensions of certain building materials, *e.g.* timber, stones, etc., as regards length, breadth, and thickness. (3) Timber less than 5 in. square.

Scapolite (*Min.*) A calcium-aluminium-sodium-chlorosilicate. Composition variable. Tetragonal; colour white, grey, or pale blue or green. It is chiefly found in metamorphic rocks, especially in those of calcareous origin. From Scandinavia, Finland, Greenland, and North America.

Scapula (*Zool.*) The shoulder blade; it is the principal member of the series of structures termed the SHOULDER GIRDLE, to which the fore limbs of an animal are attached.

Scapular, Scapulary (*Cost.*) (1) A narrow band of cloth worn across the shoulders and reaching almost to the feet. It forms part of the dress of certain religious orders. (2) A monastic hood and cloak.

Scarab (*Archæol.*) A gem carved on one side in the shape of a scarabæid beetle, and on the other side engraved as a seal; used by the ancient Egyptians as a seal and amulet.

Scarf Joint (*Carp.*) This term is applied to a variety of longitudinal joints between timbers (*i.e.* timbers fixed to each other in the same straight line). The essential characteristic of the joint is that the two members overlap, each being cut in some special manner, as distinguished from a butt joint, in which there is no overlapping. There is a great variety of scarf joints, differing in the form given to the cut surfaces and in the manner of wedging or keying up the joint.

Scarp *or* **Escarp** (*Her.*) A diminutive of the bend sinister, and half its width.

Scars (*Chem. Tech.*) The clinkers (chiefly sulphide of iron) which form in pyrites burners during the combustion of pyrites for the generation of sulphur dioxide in the manufacture of vitriol.

Scauper (*Engrav.*) (1) A tool used in wood engraving for cutting away the spaces between the lines. (2) A tool used by line engravers. *See* ENGRAVING AND ETCHING.

Scene (*Art*). (1) A landscape or view. (2) One of the divisions of an act of a play. (3) A screen or curtain suitably painted to form the background for the action of a play. (4) The stage with its surroundings.

Scheele's Green. Used as a pigment, though its poisonous nature has gradually prevented its use on wallpapers. It is arsenite of copper. Insoluble in water. Obtained by adding a soluble salt of copper such as the sulphate (blue vitriol) to a solution of potassium arsenite, when the pigment is precipitated.

Scheelite (*Min.*) Calcium Tungstate, $CaWO_4$, containing 70 to 80 per cent. of Tungstic acid. Tetragonal and hemihedral, occurring in lustrous short pyramids in various shades of yellow and brown. Its density is high, 4·5 to 5·0. Brittle. Named after Scheele, the Swedish chemist, who first discovered Tungstic acid in this mineral. From Brandy Gill and Mosedale in Cumberland, Cornwall and Devonshire, Bohemia, Saxony, Hungary, etc. Valuable as a source of Tungstates.

Scherzando, Scherzoso (*Music*). In a playful, jestful manner.

Scherzo (*Music*). A composition of a playful character.

Schiffs' Reagent (*Chem.*) A solution of magenta decolorised by sulphur dioxide; it gives a violet colour with many aldehydes. *See* ROSANILINE.

Schist (*Geol.*) The term schist is applied in France and Italy to any rocks which are fissile or split readily into thin slabs. The term is there used without any reference to the history of the rock, so that what would be called Shale, Plate, Shiver, or Blaes in Britain, as well as flagstones and also slates of all kinds, would there be termed Schist. Here, however, the use of the term is restricted to such rocks as split in certain definite directions in consequence of the development within them, by metamorphic causes, of some scaly silicate, such as mica or chlorite. Schistose structure is, in this sense, always a result of dynamic metamorphism. Any rock may be rendered schistose if it is subjected to powerful earth movements, operating at great depths below the surface and of such a nature as to give rise to a shearing movement, or flow, of one part of the rock over the next immediately below it. It is probably a result of continued physical and chemical changes in which a high temperature and the presence of water are factors of considerable importance in bringing about the metamorphic change. Schistose structure may be developed in any kind of rock, though the term schist is usually understood to imply the absence of any layers or bands containing much crystalline felspar. A rock of this latter kind would be termed a Gneiss (*q.v.*) The mineral character of a schist necessarily varies with that of the original rock affected. Thus, if potash felspar is originally present, as is the case in the arkoses of the Torridonian Rocks, Muscovite is found at the expense of the felspar, and the rock becomes a Muscovite Schist. If some original ferro-magnesian silicates are present, the rock may become a biotite schist or a hornblende schist, as the case may be. Some modifications arise through the temperature prevailing where the schist was in process of formation. Subsequent changes produced by (1) a later rise of temperature, (2) hydrometamorphism, may affect the character of the schist. Thus, if the ferromagnesian silicates are hydrometamorphosed, the rock may become a Chlorite Schist.

Schistose Structure (*Geol.*) *See* SCHIST.

Schleifer (*Music*). *See* ORNAMENTS (6), p. 479.

Schnell (*Music*). The German term for quick, as *Mässig schnell*, moderately quick. The comparative is *Schneller*.

Schneller *or* **Schnelzer** (*Music*). *See* MORDENTE, p. 413.

Schools of Painting. *See* PAINTING, SCHOOLS OF.

Schorl (*Min.*) A black variety of Tourmaline (*q.v.*) It is the commonest variety, and is a common mineral in plutonic and metamorphic rocks.

Schweinfurth Green. Sometimes called Imperial green. A somewhat obsolete pigment. It is an aceto-arsenite of copper obtained by adding acetate of copper solution to arsenious oxide (white arsenic) in water.

Schweitzer's Reagent (*Chem.*) A solvent for cellulose. *See* CELLULOSE.

Sciagraph. The plan of a building drawn in vertical section so as to afford a view of the internal structure.

—— (*Elect.*) A synonym for RADIOGRAPH, a photograph taken by the Röntgen Rays.

Sciagraphy. (1) In astronomy, the method of ascertaining the time by observing the shadows due to the sun, moon, or stars; dialling. (2) In art, the correct rendering of shadows: shading.

Science. "The classification of facts, and the recognition of their sequence and relative significance" (*Karl Pearson*).

Scimitar (*Arms*). A curved sword with the cutting edge on the convex side; a weapon peculiar to Oriental countries.

Scintillation. An expression of no very exact signification, *e.g.* the throwing off of sparks by a hot object, or an appearance of the same kind in the case of a brightly luminous or illuminated object.

Scintillation of Stars (*Astron.*) The light of stars when near the horizon does not appear steady, but scintillates or twinkles. This is a purely atmospheric phenomenon.

Sciolto, Scioltamente (*Music*). Freely; the expression is synonymous with *ad libitum* (*q.v.*).

Sclerenchyma (*Botany*). The term applied to thick walled, lignified cells met with in plants. The function of the tissue is to give support.

Sconce (*Furniture, etc.*) (1) A bracket fixed to and projecting from a wall, and intended to hold a light, generally a candle or candles. (2) The receptacle for holding the candle in an ordinary candlestick; the term is also applied to the brim which surrounds the receptacle.

Scoop Wheel (*Eng.*) A wheel resembling a water wheel, turned by power, and employed for raising water from a lower to a higher level; used occasionally in drainage and irrigation work.

Score (*Music*). Two or more staves braced together, so called from the bars being "scored" through the set of staves. Score is of five kinds: (1) full or orchestral; (2) vocal or open; (3) short or compressed; (4) pianoforte or organ score; (5) supplementary. (1) In a full score each part or set of parts of the orchestra (and voices, if any) are displayed on a separate stave. The various instruments are generally arranged in groups, *e.g.* the "Wood wind," the "Brass," the "Strings," the "Percussion"; but the order of the groups varies considerably in different scores. It will be impossible to give more than one arrangement here:

Wood wind
- Fl. Picc. (Piccolo)
- Flauti (Flutes)
- Oboi (Oboes)
- *Corno Inglese (Cor Anglais)
- Clarinetti in B (or A) (Clarionets)
- *Clar. Basso (Bass Clarionet)
- Fagotti (Bassoons)
- *Contra Fagotti (Double Bassoons)

Brass
- Corni 1, 2, in . . . } (Horns)
- Corni 3, 4, in . . . }
- Trombe in . . . (Trumpets)
- *Tromba Bassa (Bass Trumpet)
- Trombone 1 } or combined on one or two staves.
- Trombone 2 }
- Trombone 3 }
- *Tuba

Percussion
- Tympani in . . . (Kettle Drums)
- Piatti (Cymbals)
- Triangolo (Triangle)

- Arpa (Harp)

Strings (part of)
- Viol. 1 (1st Violins)
- Viol. 2 (2nd Violins)
- Viola

Voices
- Soprano
- Alto
- Tenor
- Bass

Strings (part of)
- Violoncello
- Basso (Double Bass)

- Organ

In military band scores the following instruments (or some of them) will be found, arranged somewhat in this order:

Piccolo in E♭,
Flute in E♭ (or together on one stave);
E♭ Clarionets·
Oboes;
1st B♭ Clarionets;
2nd B♭ Clarionets;
3rd and 4th B♭ Clarionets;
Tenor Clarionets in E♭;
Bass Clarionets;
Saxophones;
Bassoons;
1st Cornets;
2nd Cornets;
1st and 2nd Horns;
3rd and 4th Horns (or Saxhorns);
Baritones;
Trumpets;
Trombones;
Euphonium;
Bombardons (String Basses);
Side Drum;
Bass Drum;
Cymbals;
Triangle;
Carillon.

For examples of notation of all these instruments, see MUSICAL INSTRUMENTS (pp. 426–445) and TRANSPOSITION. (2) In vocal score each voice is written on a separate stave, with the proper clefs. The soprano clef, however, is seldom used now; in fact, the majority of modern music has the G clef for the soprano, alto, and tenor staves. In this case the tenor part is written an octave higher than it is sung. Modern vocal score therefore appears thus:

SOPRANO.

ALTO.

TENOR (*an 8va lower*).

BASS.

(3) Short score has the soprano and alto parts written on the treble stave, the soprano notes having the tails turned up, and the alto notes with the tails turned down, and the tenor and bass parts on the bass stave, the tenor notes having the tails turned up, and the bass notes with the tails turned down. Short or compressed score is also applied to orchestral works written on two staves only for performance on the organ or pianoforte, and very often having only the principal parts in full. (4) Pianoforte music is written on two staves, *viz.* the treble and bass braced together as in short score. Organ music is generally written on three staves, thus:

MANUALS.

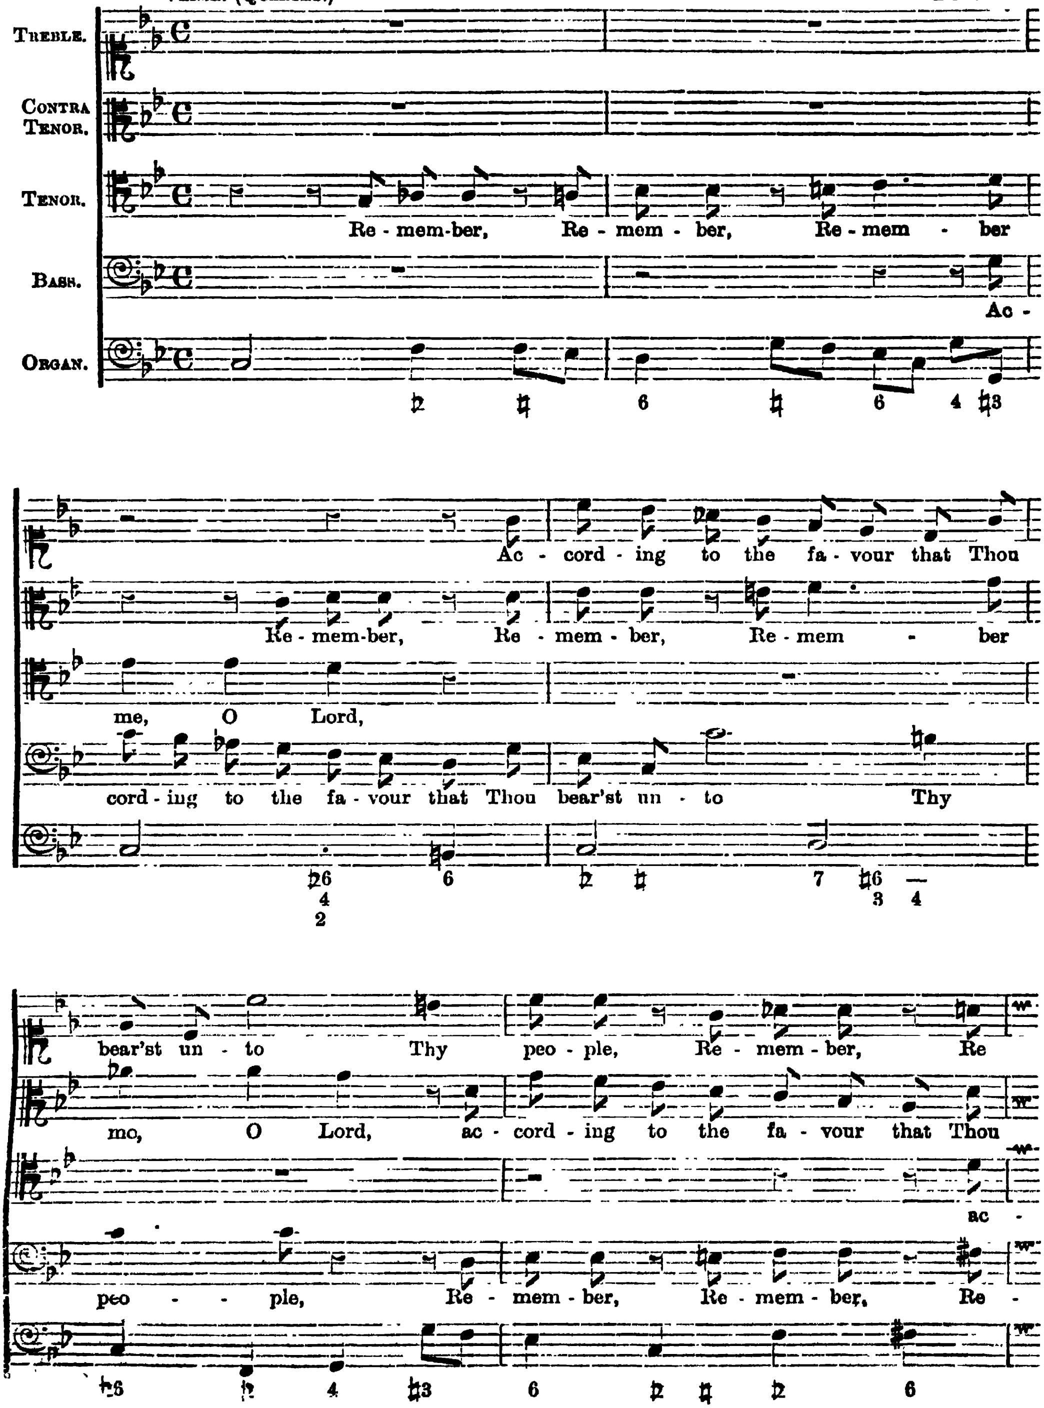
PEDALS.

In older music the organ, harpsichord, or pianoforte part of a vocal composition was printed on a single stave with the figuring of the chords. This was known as figured bass. The following examples show the beginning of the quartet from Purcell's anthem, "O give thanks," firstly, in vocal score with the figured bass organ part; and secondly, in short score with the organ part, as it should be played.

* These instruments are less frequently met with.

EXAMPLE OF VOCAL SCORE WITH FIGURED BASS.

VERSE. (QUARTET.) PURCELL.



EXAMPLE OF SHORT SCORE WITH ORGAN ACCOMPANIMENT.

(5) Supplementary score is an arrangement for certain instruments, such as the "percussion" or trombones, placed at the end of the full score, when owing to lack of space it is found impossible or difficult to print them on the one page. *See also* CLEF, STAVE, *and* TRANSPOSING INSTRUMENTS.

Scoria (*Geol.*) A general name for the larger fragments of vesicular lava ejected from a volcano during explosive eruptions. But an eruptive rock is said to be scoriaceous if it happens to be full of vapour cavities so as to resemble a sponge.

—— (*Met., etc.*) (1) Slag of a cindery character. (2) The recrement of fused metals.

Scorification (*Met.*) The addition of lead to copper which is required for rolling into sheets; the term refers to the production of scoriæ, which occurs on the surface of the fluid metal.

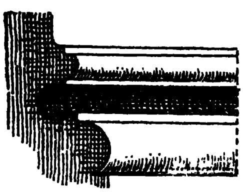
Scotch Dressing (*Cotton Manufac.*) *See* DRESSING.

Scotch Pig Iron (*Met.*) Iron from the Clyde districts, chiefly made from black band or clay ironstone; it is much used for ordinary foundry work.

Scotch Snap (*Music*). The peculiarity of a short note preceding a long one in Scotch melodies, especially the strathspeys.

Scotch Tuyere (*Met.*) A TUYERE (*q.v.*) cooled by water circulating in a pipe coiled round the tuyere.

Scotia (*Architect.*) A hollow moulding frequently used in the bases of columns in Greek, Roman, and Renaissance architecture. It separates the two torii in the Attic base. It is also known as a Trochilus, and a similar moulding used in Gothic architecture is known as a Casement or Casemate. *See* ATTIC BASE *and* CASEMATE.



SCOTIA.

Scouring. Cleaning by rubbing with sand and water or dilute acid; used in tin plate manufacture.

—— (*Leather Manufac.*) The scouring or cleaning of leather after the rough tanning has been done, and previous to polishing and finishing. Scouring may be effected by hand or machine, with brush, stone, brass, or steel tools, or by rotating the leather in a drum with sumach.

—— (*Woollen or Worsted Manufac.*) This term relates to the washing of wool, yarn, and cloth, the machines for each being entirely different in construction.

Scraper (*Bind.*) A steel implement used for scraping the edges of books in order to secure an even surface before gilding or burnishing.

—— (*Eng.*) The tool used in SCRAPING and SURFACING metal (*q.v.*) It usually consists of an old file ground to a sharp edge of convenient shape.

—— (*Joinery, etc.*) A flat blade of steel used in smoothing a wooden surface. The edge is usually ground and set at a right angle, and a smooth piece of steel is drawn along it in order to produce a wire edge or burr, which serves as the actual cutting edge.

Scraping (*Eng.*) The final process of preparing an accurately plane surface where a very good fit is essential: totally distinct from scraping woodwork, which aims at a good appearance only. The irregularities of the surface are found by rubbing a film of red lead and oil on a SURFACE PLATE (*q.v.*) or on an already finished surface which has to make a fit with the one being operated on. On placing the two surfaces in contact, patches of red lead appear on the projecting portions, and these are cautiously removed by the scraper, and the test is repeated. The process is slow and laborious, but the results which can be obtained in this way are marvellously accurate, and cannot be approached by any other method in engineering work.

—— (*Joinery, etc.*) Smoothing the surface work with the SCRAPER (*q.v.*) preparatory to final finishing, varnishing, etc.

Scrap Iron *or* **Scrap** (*Eng.*) Old iron, whether cast or wrought. The former is re-melted along with fresh pig iron for foundry use, and the latter can be re-welded if of sufficiently good quality.

Scrap Steel (*Met.*) Scrap steel is added to the charge in certain processes for the production of steel, *e.g.* the Open Hearth and Siemens Processes (*q.v.*)

Scratched Figures (*Typog.*) Figures with a line drawn diagonally across the face, as $\cancel{1}$, $\cancel{2}$, $\cancel{3}$: used in mathematical works.

Scree (*Geol.*) *See* SCREES.

Screed (*Plastering*). (1) A narrow line of plaster laid to the desired thickness, and when hard used as a guide for the floating rule. (2) A narrow ground of wood fixed as a guide for plastering.

Screen (*Carp. and Join.*) Framing, either panelled or having the upper part glazed; used as a partition.

—— (*Lantern Work*). A flat white surface, either opaque or transparent, according as the lantern is placed in front of or behind the screen. The former method is much the better. In this case the best screen is a surface coated with dead white plaster; a whitewashed wall is perhaps next best; then a good paper faced screen. The common linen screen is far too transparent, but owes its popularity to its portability.

——, **Electric.** A closed conductor within which a piece of apparatus (*e.g.* an electroscope) can be placed in order to protect it from external electrical influences. A fairly effective screen may be formed by metal gauze or even by a wire cage.

——, **Magnetic.** A closed or nearly closed case or cover of thick iron for protecting magnetic apparatus from external magnetic influences. The shielding effect is never as complete as in the corresponding case of an electric screen.

——, **Methuen's.** *See* METHUEN SCREEN.

——, **Photozincographic.** *See* PROCESS WORK.

Screes (*Geol.*) A term originating in the north of England, but now used elsewhere, and applied to the long trains of rock fragments which strew the slopes of a hill below a crag, and which are due to the weathering of the rock which forms the crag. In most cases they represent the amount of disintegration of the parent rock since the close of the Age of Snow.

Screw. If a helical groove be cut on a cylindrical (or conical) object a SCREW is produced. The portion of the original material which remains between the parts cut away in forming the groove is termed the THREAD of the screw. The distance between

consecutive turns of the thread is termed the PITCH of the screw. The DEPTH OF THE THREAD is the depth of the groove; the FORM OF THE THREAD is the shape of its cross-section when cut by a plane passing through the axis of the screw: if the groove be rectangular in form, a SQUARE THREAD is produced. *See also* SCREW THREADS. The cutting of the groove which forms the thread produces a new surface of peculiar character, which forms the sides of the thread; this is known as a SCREW SURFACE, and may be considered (mathematically) to be produced as follows: Let a fixed straight line be taken to represent the AXIS of the screw, and let another line, termed the GENERATING LINE, intersect it at a constant angle. Then if the generating line rotate uniformly about the axis, and at the same time the point of intersection move uniformly along the axis, the surface generated by the motion will be a Screw Surface. The pitch of the screw surface will be the distance which the point of intersection moves along the axis during one revolution of the generating line. If two (or more) grooves be cut round the same cylinder, parallel to each other, a TWO-THREADED (or MULTIPLE-THREADED) SCREW is produced. A screw usually turns in a NUT, an object having a cylindrical hole provided with a replica of the screw thread, into which the screw fits smoothly. A single turn of the screw relative to the nut causes a relative longitudinal movement between the two, equal in amount to the pitch of the screw. Screws in practice are usually of metal, wood being employed in a few instances only, *e.g.* for carpenters' bench vices, wood clamps, etc. Metal screws are cut by stocks and dies, screw cutting lathes, screwing machines, etc. (*q.v.*) The nut is formed by taps (*q.v.*) or by a lathe or machine. The process of cutting screws by the use of a chaser (*q.v.*) was once common, but is now almost obsolete, except in some kinds of light work, *e.g.* the formation of a thread on a thin tube, such as is used in some optical instruments. The uses of screws are readily classified under two heads: (1) As a means of fastening (*e.g.* wood screws, bolts and nuts, etc.); (2) as a means of producing regular linear motion (*e.g.* the leading screw of a screw cutting lathe, in a screw jack, screw gauge, etc.)

Screw Barrel (*Eng.*) A cylindrical roller or drum having a helical groove (*see* SCREW) cut in its surface for the reception of a chain which is wound up on the drum.

Screw Blade (*Eng.*) The blade of a SCREW PROPELLER (*q.v.*)

Screw Bolt (*Eng., etc.*) An ordinary BOLT (*q.v.*)

Screw Chase (*Typog.*) Screw chases are used chiefly for newspaper work. The type is secured by the action of set screws instead of quoins.

Screw Chasing (*Eng.*) Cutting screws by hand with a CHASING TOOL, a flat bladed tool having teeth corresponding to the form of the thread. This tool is moved along the top of the rest as the work rotates in the lathe. By properly judging the rate of motion a screw thread can be cut with fair accuracy.

Screw Clamp (*Join., etc.*) A device for holding the parts of a piece of work in place or for forcing them into position. The requisite pressure is applied by means of a screw. The tool may be made of either wood or metal.

Screw Composing Stick (*Typog.*) A form of composing stick in which the slide is secured by means of a screw and slotted nut instead of by a spring. *See* TYPOGRAPHY.

Screw Cutting (*Eng.*) This term is usually applied to the cutting of screws in the SCREW CUTTING LATHE (*q.v.*) Screws are also cut by CHASING, by STOCKS AND DIES, and by SCREWING MACHINES (*q.v.*)

Screw Cutting Lathe (*Eng.*) A lathe in which the slide rest carrying the cutting tool is made to travel along the bed with a uniform velocity, which is duly proportioned to the rate of rotation of the work in the lathe. This "travel" is obtained by the LEADING SCREW, a square threaded screw actuating a nut fixed to the slide rest. The rate of rotation of the screw is governed by a train of CHANGE WHEELS, connecting the leading screw to the mandrel of the lathe. The wheels are so chosen that the tool travels through a distance equal to the PITCH of the screw (*see* SCREW), while the mandrel makes one revolution.

Screw Dies (*Eng.*) *See* STOCKS AND DIES.

Screw Driver. The tool used for driving in or drawing out screws which are provided with a slotted head, whether in wood or metal work. The blade is often made broad, in order to give stiffness; but a circular section, of diameter not exceeding that of the screw head, is preferable. The handle should be broad, to afford effective leverage.

Screw Driver Bit (*Carp., Eng., etc.*) A screw driver blade made to fit a BRACE (*q.v.*)

Screw Feed (*Eng., etc.*) Mechanism in which the feed of a cutting tool, or slow motion of any other part, is obtained by a screw and nut.

Screw Gauge. An instrument for measuring the length or diameter of small objects with accuracy. A well cut screw, whose pitch is exactly known, turns in a nut fixed to the frame of the instrument; a stop is attached to the latter in line with the axis of the screw, so that by rotating the screw, a gap or opening of any desired width (up to the limit allowed by the dimensions of the instrument) may be formed. The object to be measured is placed in this gap, and the screw adjusted till the object fits exactly, without shake, between the stop and the end of the screw. The exact distance between the two latter may be read off on a scale engraved on the apparatus.

Screw Gearing (*Eng.*) (1) Worm gearing (*q.v.*) (2) Gear wheels whose teeth are not at right angles to the plane of the wheel. The teeth in this case may form portions of screw threads; such gearing is useful for connecting two shafts making an angle with each other.

Screw Head. The top part of a screw, by means of which it is turned. It may be either SLOTTED, as in wood screws, or SQUARE, HEXAGONAL, etc., to fit a spanner or key, or MILLED (*q.v.*) to enable it to be turned by hand.

Screwing (*Eng., etc.*) (1) The cutting of screw threads. Applied especially to cutting threads by means of dies worked either by hand or by a SCREWING MACHINE (*q.v.*) (2) Turning a screw or nut in order to cause it to advance or recede.

Screwing Machine (*Eng.*) A machine usually resembling a lathe in form, by means of which a succession of similar screw threads can be rapidly cut on the ends of bolts, rods, etc. The rod may pass through a hollow mandrel, and the dies be fixed; or the dies may rotate in jaws fixed on the mandrel,

and the work be held in a slide rest. The former method is adopted when a number of similar screws are being made from one length of rod. Various tools for cutting and finishing the screw, as well as the screwing dies, are fixed in a TURRET (*q.v.*), and can be caused to act on the work in succession. In some machines the whole of the operations are made automatic, when one workman can attend to a number of machines.

Screwing Tackle (*Eng.*) STOCKS AND DIES, TAPS, etc. (*q.v.*), used in producing screws by hand.

Screw Jack (*Eng.*) A portable device for raising heavy weights through a small distance. It consists essentially of a vertical screw working in a nut supported on a suitable frame or body. The screw is turned by force applied at the end of a lever handle or bar, which is put through a hole in the head of the screw; the screw rises slowly, exerting very great lifting force.

Screw Key (*Eng., etc.*) A SPANNER (*q.v.*)

Screw Mandrel (*Eng.*) A TRAVERSING MANDREL (*q.v.*)

Screw Micrometer. A piece of apparatus for the accurate measurement of small distances, based on the motion of a screw. A SCREW GAUGE is a form of screw micrometer.

Screw Nail (*Carp.*) An old and somewhat misleading term for a WOOD SCREW. *See* SCREW.

Screw Pile (*Civil Eng.*) A PILE (*q.v.*) with a screw at the lower end. It is driven into the ground by rotation instead of by blows from a falling weight. *See* SCREW.

Screw Plate (*Eng., etc.*) A hard steel plate forming a number of dies for cutting small screws. Screwed holes are made in the plate, and very often slots are cut in opposite sides of the hole, so as to form cutting edges. Screw plates are inferior to STOCKS AND DIES (*q.v.*), which are used for larger work.

Screw Press. A device for exerting pressure by means of a powerful screw, which acts on the object to be compressed.

Screw Propeller (*Eng.*) Often termed a Screw or a Propeller. It consists of a central HUB or BOSS, mounted on the propeller or screw shaft which projects from the stern of the vessel. From this boss project two (or more) BLADES, which form parts of two modified screw surfaces. *See* SCREW. The propeller is usually made of Manganese Bronze (*q.v.*), and may either be cast in one piece, or the blades may be attached separately to the boss. Two screws are often used in modern vessels, one being placed on each side of the keel post; this arrangement, termed TWIN SCREWS, necessitates, of course, the fitting of two engines and propeller shafts, which are completely independent of each other.

Screw Shaft *or* **Propeller Shaft** (*Eng.*) The steel shaft which communicates the motion of the engines to the propeller of a steamship. It is carried on bearings rigidly fixed to the lower part of the framing of the vessel. The longitudinal force on the shaft is balanced by a THRUST BLOCK (*q.v.*) The shaft and its bearings run in a tunnel, along which a man can pass in order to examine and lubricate the bearings.

Screw Stock (*Eng.*) *See* STOCKS AND DIES.

Screw Surface. *See* SCREW.

Screw Tap (*Eng.*) A TAP (*q.v.*) for cutting an internal thread.

Screw Threads (*Eng., etc.*) The threads of screws vary in two particulars—form or shape, and pitch. The form of a thread is the shape of its cross section; this is usually square, rounded, or angular. The top and bottom of an angular thread are rounded in the case of the usual English type, known as the WHITWORTH THREAD; in the American STANDARD THREAD they are flattened. These two forms of thread are shown in the figures. Fig. 1 shows the section of the Whitworth Thread; the angle is 55°, and the top and bottom are rounded

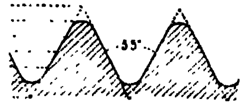


FIG. 1

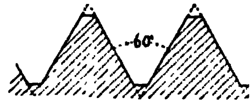

FIG. 2.

off to one-sixth of the depth. Fig. 2 shows the American Standard Thread, the angle being 60°, and the top and bottom being flattened. The width of the flat in each case is one-eighth of the pitch of the screw. The pitches of the principal threads are as follows:

(1) WHITWORTH THREADS.

Diameter in inches.	No. of threads per inch.	Diameter in inches.	No. of threads per inch.
$\frac{1}{4}$	20	1	8
$\frac{3}{8}$	16	$1\frac{1}{4}$	7
$\frac{1}{2}$	12	$1\frac{1}{2}$	6
$\frac{5}{8}$	11	$1\frac{3}{4}$	5
$\frac{3}{4}$	10	2	$4\frac{1}{2}$
$\frac{7}{8}$	9		

(2) GAS THREADS.

Diameter in inches	No. of threads per inch.
$\frac{1}{8}$	28
$\frac{1}{4}$ and $\frac{3}{8}$	19
$\frac{1}{2}$ and $\frac{3}{4}$	14
1 and upwards	11

(3) AMERICAN STANDARD THREAD.—The pitch follows very closely the Whitworth Thread given above.

(4) BRITISH ASSOCIATION or B. A. THREADS.—A standard for small screws used in electrical and other scientific work. The different sizes are numbered as follows:

Number.	Diameter in millimetres.	Pitch in millimetres.
0	6·0	1·0
1	5·3	·9
2	4·7	·81
3	4·1	·73
4	3·64	·66
5	3·2	·59
6	2·8	·53
7	2·5	·48
8	2·2	·43
9	1·9	·39
10	1·7	

(5) INTERNATIONAL STANDARD THREAD.—This is

also a millimetre thread, recommended by an International Congress in 1898:

Diameter in millimetres.	Pitch in millimetres.
6 and 7	1·0
8 and 9	1·25
10 and 11	1·5
12	1·75
14 and 16	2·0
18 to 22	2·5
24 to 27	3·0
30 to 33	3·5
36 to 39	4·0
42 to 45	4·5

Screw Tool (*Eng.*) A slide rest tool whose end is formed to correspond to the groove cut in forming a screw thread; it may be square, V-shaped, etc.

Screw Wrench (*Eng.*) A SPANNER (*q.v.*) with jaws whose distance apart can be adjusted by means of a screw, to fit different sized nuts.

Scribe, Scriber, *or* **Scribing Iron** (*Eng.*) A tool having a sharp point or edge, used for marking lines on metal or wood.

Scribed Joint (*Carp. and Join.*) *See* SCRIBING.

Scribing (*Eng., Carp., etc.*) (1) Marking lines on metal, wood, etc., preparatory to cutting the material to any required form. (2) Cutting the end of a piece of moulding to the profile of another piece, so that the two may fit closely together: *e.g.* the bars of a window sash are generally scribed at their ends, where they meet another bar or the frame of the sash. The mouldings thus intersect each other exactly: but there is no weakening of one member such as would be produced if the joint were mitred.

Scribing Block (*Eng.*) A support carrying a scribe, which can be fixed in various positions. The base of the support or block is usually an accurately plane surface which is laid on a SURFACE PLATE (*q.v.*) If the block be moved about on the surface plate, the point of the scribe moves parallel to the plate; hence lines can be marked on a piece of work, so as to be accurately parallel to a face of the work which rests on the surface plate.

Scribing Gouge (*Carp. and Join.*) A gouge which has the bevelled edge on the concave side; a PARING GOUGE. Used by joiners in making a scribed joint.

Scrim (*Dec.*) Thin canvas used for covering battened walls before papering.

Scrinium (*Archæol.*) A case, generally cylindrical in form, used in early times for holding writings, etc., *e.g.* parchment rolls.

Scrip (*Archæol.*) A wallet or pouch such as was carried by pilgrims. Used in Heraldry as a charge, often in conjunction with a pilgrim's staff.

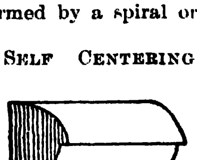
Script (*Typog.*) The name of a style of type imitating writing.

Scroll (*Carp. and Join.*) The ornamental curved end of a handrail.

—— (*Dec.*) An ornament formed by a spiral or involute curve.

Scroll Chuck (*Eng.*) A SELF CENTERING CHUCK (*q.v.*)

Scroll Moulding (*Architect.*) A Gothic moulding characteristic of the Decorated period and consisting of two half rounds, the upper one projecting slightly beyond the lower. *See also* ROLL MOULDING.



Scroll Opener (*Textile Manufac.*) The appliance used for keeping the cloth fully stretched in the process of scouring. It consists of a pair of scroll rollers and a tensioning frame for keeping the cloth in the centre of the main rollers of the scouring machine.

Scrubbers (*Gas Manufac.*) *See* GAS MANUFACTURE.

Scrutoir (*Furniture*). A writing desk with a hinged flap or door which, when open, forms a table for writing upon; an escritoire.

Scudding (*Leather Manufac.*) Removal of the SCUD, a term applied to the impurities, such as fat glands, hair roots, pigment cells, lime salts, etc. This is done in the wet state by working the skins over a beam with a blunt knife or a slate while in the limed or "pucred" state.

Sculls (*Met., etc.*) Skins of metal, slag, scale, etc., which form on the inside of foundry ladles, and remain after the fluid metal is poured out.

Sculpsit (*Engrav., etc.*) This Latin word, placed after the name of an individual on an engraving or on a piece of statuary, indicates the engraver and the sculptor respectively. Abbreviation, *sculp.* or *sculps.*

Sculptor's Varnish. *See* VARNISHES.

Sculpture, Schools of. The history of sculpture can be carried back much farther than that of painting, because the permanency of the materials used by sculptors has made possible the preservation of many works executed in very remote ages. It begins really with the scratched and chipped bones which represent the tentative efforts of prehistoric man, but its continuous record starts more than thirty centuries before the Christian era in that cradle of the arts, Egypt. The earliest known EGYPTIAN SCULPTURES suggest by the accuracy of their convention, and the technical skill that they reveal, a long preparatory period of which no traces now remain. The greater merits of the existing examples are the true understanding of individual character which distinguishes the works from nature, and the dignified sense of design which even the formalities of the style chosen do not entirely disguise. Contemporaneous with the later Egyptian school was that of ASSYRIA, which produced the great winged bulls, the exquisite bas-reliefs of hunting scenes and other incidents in the life of the period, and the representations of kings and dignitaries, which are all justly reckoned among the most memorable instances of the art of sculpture that the world has seen. We have in the British Museum several of the best of these carvings, and there are others of much importance in the Louvre. The next development was that of the GREEK SCHOOL. This began in a primitive fashion as early as 1000 B.C., and its archaic stage lasted for nearly five hundred years. Then came a brief transitional period, which was followed immediately by what is known as the Great Age of Greek sculpture. The chief artist of the transition was Myron, a copy of whose "Throwing Discobolus" is to be seen at Rome with other copies of his works. The first, and perhaps the greatest, of the sculptors of the Great Age was Phidias, a younger contemporary of Myron. He is thought to have been born about 480 B.C., and is known to have completed his great gold and ivory statue of Athene for the Parthenon in 438. The exquisite sculptures from

the Parthenon, which are preserved in the British Museum, are also thought to have been inspired and supervised by Phidias; some of them may have been actually executed by him, but the bulk were probably carried out by his pupils. Among the contemporaries of Phidias were Polyclitus of Argos, copies of whose works exist at Naples and Berlin. Early in the fourth century B.C. flourished Scopas, and Praxiteles, one of the greatest of the Greek sculptors, who executed the often mentioned "Aphrodite of Cnidus," the superb "Hermes" at Olympia, and probably the "Leaning Satyr" at Rome. To Scopas is assigned, but on questionable authority, the group of "Niobe and her Children," of which copies are preserved at Florence. The last sculptor of the Great Age was Lysippus of Sicyon, who is supposed to have been the author of the "Apoxyomenos" in the Vatican. Then succeeded a period of less distinction, during which both the taste and the power of the Greek sculptors degenerated. To the commencement of it belong two of the chief treasures of the Louvre, the "Victory of Samothrace" and the "Aphrodite of Melos"; but as it went on, affectations and a desire for sensation—illustrated in such works as the "Apollo Belvedere" and the "Laocoön"—crept in and destroyed the purity of the classic style. Among the ROMANS the art of sculpture had no real vitality. Hardly any original works were produced, and the sculptors, who were usually Greeks and often slaves, occupied themselves chiefly with imitations or copies of the earlier Greek masterpieces. The early Christians, too, though they to some extent encouraged painting, disregarded sculpture almost entirely. The first steps towards the foundation of a new school were taken early in the thirteenth century of the Christian era, when Nicola Pisano created a tradition which, though it was akin to the antique in its respect for beauty, was essentially inspired by the spirit of the times. This tradition was carried further by his son Giovanni, and after him it was developed by a succession of great craftsmen into a guiding principle which determined the whole direction of ITALIAN SCULPTURE. Towards the end of the fourteenth century appeared Ghiberti, who executed the great gates of the Baptistery at Florence, and Donatello, a sculptor of exquisite skill and refinement. Then came Luca Della Robbia, born in 1400, the head of a family which became famous by the beauty of the work which they accomplished in coloured and glazed terracotta; and lastly came, in 1474, Michael Angelo Buonarroti, the greatest of all the Italian sculptors, and the man in whom the movement which had been in progress for more than two centuries finally culminated. He may fairly be called the Phidias of the Renaissance; but, unlike the Greek master, he had no successors of anything like the same rank. In 1504 he finished his colossal statue of David at Florence, and in the following year he commenced the monument of Julius II., which was never finished. In 1524 he began the Medici tombs for the sacristy of San Lorenzo at Florence, which were completed nearly ten years later. These are perhaps his greatest works. While Michael Angelo was working there was growing up in France a school of much importance. The first man of note in it was Michel Columbe, who was born about 1430; but he was surpassed by his sixteenth century successors, Jean Goujon and Germain Pilon, the former of whom executed the "Diane Chasseresse," now in the Louvre, and the latter the group of the "Three Graces." With them began a long list of able sculptors, which includes many famous names—for instance, C. M. Clodion (1738—1814), J. A. Houdon (1741—1828), J. Pradier (1792—1862), P. J. David (1789—1856), F. Rude (1784—1855), and A. L. Barye (1796—1875); and moderns like J. B. Carpeaux, E. Frémiet, A. N. Cain, H. M. Chapu, J. A. Falguière, A. Mercié, Jules Dalou, and Auguste Rodin. By the efforts of artists such as these the French school of sculpture has been given in the history of the art a place of very great distinction. In ENGLAND the native school may be said to have begun with John Flaxman (1755—1826), a contemporary of the Italian Canova (1757—1822), and the Dane Thorwaldsen (1770—1844), and, like them, a follower of the classic tradition. After him came Chantrey (1782—1841), Westmacott (1775—1856), John Gibson (1780—1866), and M. C. Wyatt (1778—1862), and others of considerable ability. The greatest development of English sculpture has come, however, during recent years. It promises to attain in the future a position of much more prominence than it has reached in the past. In GERMANY also and BELGIUM there are recent schools, which are growing in importance; and there are some sculptors of ability in Russia and America.—A. L. B.

Scumbling (*Art*). (1) Softening the colours of an oil painting by blending with a neutral tint which is applied comparatively dry by means of a brush or the finger. (2) Softening the outlines of a drawing by rubbing with the stump or the blunt end of the chalk.

Scum Cock (*Eng.*) A tap or cock in a boiler used for drawing off the floating scum from the surface of the water.

Scutcheon (*Her.*) *See* ESCUTCHEON.

Scutching (*Cotton Manufac.*) A further process of opening (*q.v.*) and cleaning. The cotton in this case is fed in a uniformly rolled lap form, three or four being run together. *See also* COTTON MANUFACTURE.

—— (*Linen Manufac.*) After the flax has been steeped or retted and grassed, the bone or woody portion of the stem is cleared away from the fibre. The process, called scutching, consists of placing the flax in handfuls over an upright slab, and beating the ends of it with a blade till all the bone is cleared away. This is usually done in mills by means of revolving blades driven by water power.

Scutum (*Arm.*) A large oblong shield used by the Romans. It was constructed of some light material, covered with hide, and curved so as to fit close to the body.

Sdegno, Con (*Music*). With scorn.

Se (*Chem.*) The symbol for SELENIUM (*q.v.*)

Sea Beach (*Geol.*) Strictly speaking, a sea beach is a deposit of sand and shingle piled upon the shore platform by the action of the waves; but the term is often applied to the rock-shelf gradually hewn between tide marks by the prolonged mechanical action of the waves.

Sea Breeze (*Meteorol.*) *See* LAND AND SEA BREEZES.

Sea Cock (*Eng.*) A tap or cock in a tube leading from the sea water into the condenser of a marine engine.

Sea, Erosion by (*Geol.*) The mechanical erosion effected by the sea usually takes place between tide marks, and in the majority of cases this action mainly consists in the gradual reduction in size and the ultimate removal of rock material detached by
